At Manhattan, the tusks and skeleton of a mastodon or some similar animal were unearthed at the Thomas placer claim at a depth of 70 ft. The main gulch is yielding gravel averaging \$4.60 per cubic yard. The White Caps lessees' dump contains 1400 tons of \$16 ore, and 35 tons per day is being added to it. The east ore-shoot is being mined from the 165 to 300-ft. level and is 125 ft. long. High-grade ore is still being extracted from the Manhattan Crescent, and the Reilly Fraction operators have treated 12,000 tons. About \$9 per shift is being won from the Dexter No. 14 placer claim near the town.

The mines at Tonopah produced 11,731 tons of ore, worth \$277,250, during the week ended October 11. The West End mill yielded 28,335 oz. bullion and 28 tons of concentrate in September, and the Extension \$51,200 from 4847 tons of ore.

OREGON

BAKER COUNTY

The Sumpter dredge of the Powder River Gold Dredging Co. has been in continuous operation for 10 months and is handling 8000 cu. yd. per day of 24 hours. A total of 450 hp. is used by the various motors, and the gold production is reported to be satisfactory.

UTAH

JUAB COUNTY

The new mill for the Knight interests has been started and will treat ore from the Colorado, Iron Blossom, and Black Jack mines.

SALT LAKE COUNTY

The United States Smelting, Refining & Mining Co. has acquired the Last Chance mine at Bingham, at a price stated to be about \$100,000. The property is a valuable one and has produced \$1,500,000 in gold, silver, and lead.

It has been developed by three adits, the lower of which is 3200 ft. long.

The Lost Packer Mining Co., which operates a rich copper mine and smelter in the summer only in Custer county, Idaho, has declared a dividend of 25c. per share.

WASHINGTON

FERRY COUNTY

Further litigation is probable between J. L. Harper, R. A. Koontz, J. L. McCormick, S. L. Boyer, and others who are interested in the Republic Mines Corporation, Imperator-Quilp Mining Co., and North Washington Power & Reduction Co., with interests in the Republic district.

STEVENS COUNTY

The Copper King mine at Chewelah is shipping ore to the Granby smelter at Grand Forks, British Columbia, and returns leave \$12 per ton net. The vein being mined is 23 ft. wide. At the United Copper the lower adit is in 2700 ft., and small veins of copper ore have been cut. Eighty men are employed at the mine and mill.

CANADA

BRITISH COLUMBIA

The Hedley Gold Mining Co. has increased the wages of employees 25c. per day, taking effect on September 1. The Granby Consolidated Mining, Smelting & Power Co., with mines at Phoenix and Hidden Creek, and a smelter at Grand Forks, produced 22,688,614 lb. copper, 324,336 oz. silver, and 47,266 oz. gold, worth \$4,782,691, during its fiscal year ended June 30, 1913. The net profit was \$1,214,599, dividends paid were \$449,955, and surplus \$683,149. The total surplus is \$3,199,271. Ore reserves at Phoenix have not been fully maintained, and are 5,613,000 tons, containing 17.68 lb. of recoverable copper. At Anyox (Hidden Creek properties) the reserves are 7,759,000 tons of 2.2% ore, and the 2000-ton smelter here will commence early in 1914. During the week ended October 7, the Grand Forks smelter treated 22,979 tons of ore, yielding 262,000 lb. of copper, and for the year to date 945,529 tons and 16,609,997 lb., respectively.

ONTARIO

During September the Nipissing high and low-grade mills treated 156 and 6879 tons of ore, respectively, and the refinery produced 728,204 oz. silver valued at \$442,588. The

NIPISSING MILL, COBALT.

monthly report shows that the hydraulic giant is working on Keewatin between veins 19 and 22. The diamond-drill is on its third hole in the diabase of 408 near the Nova Scotia. No new veins were cut in the mine. A drift near the surface of No. 8 shows the vein to be 2 to 8 in. wide, consisting mainly of calcite and smaltite, averaging low-grade ore.

At Porcupine, the Hollinger mill treated 12,264 tons of ore during the four weeks ended October 8. This averaged \$17.80 per ton with 96.4% extraction, giving a profit of \$145,867. Working costs averaged \$5.18 per ton. The 425-ft. level is proving quite satisfactory, and the shaft will be sunk to 550 feet.

KOREA

Details of the August clean-up of the Oriental Consolidated stamp-mills and cyanide plants, which treated 27,962 tons of ore, are as follows: Tabowie mill, \$29,601; Taracol

mill, \$21,143; Kuk-San-Dong mill, \$5545; Maibong mill, \$15,650; Candlestick mill \$7010; Taracol tube-mill, \$59,233; Kuk-San-Dong cyanide plant, \$5163; Kuk-San-Dong dump plant, \$3455; and Candlestick cyanide plant, \$1914; making a total of \$148,714.

The rainy season is now over, and there has been an unusually small amount of rain this year, at present there being but 15 ft. of water in the Chorrie reservoir, or sufficient for a week's full run for the electric-power plant. Owing to the small amount of rain, the plants could operate at full efficiency during August, as there was no trouble with water in the mines. All plants ran steadily during August except the Kuk-San-Dong dump plant, which was closed the first 18 days of the month owing to lack of liners for the tube-mill. The extraction for August in the Taracol tube-mill was 87.2 per cent.

The September clean-up at the Oriental Consolidated mills was worth \$131,855.

MEXICO

SONORA

The Lucky Tiger-Combination Gold Mining Co., operating at El Tigre, reports that exploration work with diamond-drills has been done in the Gold Hill portion of the mine, and later followed the most favorable indication by a cross-cut from the second level on the Tigre vein, which resulted in the following message from the general manager, L. R. Budrow, on September 26: "Cut vein in cross-cut from Brown shaft, 20 in. wide, assaying 295 oz. silver and 3 to 10 oz. gold (\$193) per ton. Selected samples assay 800 oz. silver and 4 to 10 oz. gold (\$488) per ton. Its extent is unknown, but the lode looks exceedingly promising. Shall commence to drive on the lode and cross-cut from the third level (100 ft. below second level)." This is an entirely new vein, about 150 ft. east of and parallel with the Tigre vein, as is also the Sooy vein on the west. Some of the richest ore was opened around the Brown shaft and Gold Hill on other levels, and present indications add greatly to the value of the property. Notwithstanding the political difficulties existing in Mexico, the district in which the property is situated has been exceedingly quiet throughout the entire year.

NICARAGUA

The Bonanza and other mines have been sold to the Canadian Agency, Ltd., of New York, the transfer taking place on October 10.

Schools and Societies

COLUMBIA UNIVERSITY will hold on May 27, 28, and 29, 1914, at New York, a celebration of the fiftieth anniversary of the founding of the Columbia School of Mines. The present plans provide for three days of a social, academic, and historical character, but any other suggestions will be gladly received from those interested.

The POLYTECHNIC EVENING HIGH SCHOOL of Los Angeles opened on September 15. The department of chemistry is under the direction of M. S. Moore. The curriculum for the four half-years is: mineralogy and mining chemistry; introductory geology and mining chemistry; mining geology, mining, and ore dressing; metallurgy and mine engineering, respectively.

The AMERICAN PETROLEUM SOCIETY was organized September 10 at the Experiment Station of the U. S. Bureau of Mines, Pittsburgh, Pennsylvania. This organization is the result of an effort of the Bureau for the past seven years to bring together the men interested in the petroleum industry. The final organization was completed on September 10. This society will concern itself with the study of all phases of natural gases and petroleum, including the origin, statistics, conservation, drilling methods, production, transportation, storage, refining, and specifications for refined products. The first annual meeting will be held at a place to be selected in the spring of 1914, and the second in San Francisco in 1915.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

STANLEY DE LA MARE is in London.

CHARLES BUTTERS is in New York City.

M. K. ROGERS was in San Francisco recently.

R. H. CHAPMAN has left Yerington for Washington, D. C.

G. M. COLVOCORESSES is in the West on professional work.

GEORGE I. COHN has returned from Charcas to New York City.

SYDNEY H. BALL returned to New York from Europe recently.

W. BODYCOAT is with the Abosso Gold Mine, of Abosso, West Africa.

N. NESTOR-SHERMAN is with the Tata Iron & Steel Co., Ltd., of Sakchi, India.

C. W. PURINGTON expects to arrive in London from the Lena gold district about October 10.

ROBERT LINTON, who has been examining properties in Gunnison county, Colorado, has gone to New York.

E. C. ECKEL and E. E. ELLIS were in New York last week to testify in the Steel Corporation dissolution suit.

R. P. McLAUGHLIN will study the water situation in the oilfields of California for the State Mining Bureau.

SIMON GUGGENHEIM, MURRY GUGGENHEIM, and M. H. DODGE returned from Europe on the *Imperator*, October 9.

E. K. SOPER has returned to the University of Minnesota from Coahuila, Mexico, where he has been during the past year.

JAMES IRVING recently made an examination of the Arizona Venture Co.'s property situated in Mohave county, Arizona.

R. M. SYLVESTER, general manager for the Granby Power, Light & Smelting Co., has been made a director of the corporation.

N. M. MUIR has left San Francisco to become superintendent for the Arizona Belmont Mining Co., at Silverbell, Arizona.

LEON PERRET, general manager for the Lenskol Gold Mining Co., has engaged R. E. SMITH as his chief technical assistant.

A. J. EVELAND has severed his connection with Hornblower & Weeks and will hereafter devote his time to consulting work, with offices at 42 Broadway, New York City.

CHARLES HAYDEN and D. C. JACKLINE have been in Butte inspecting the Butte & Superior property. They left there for Seattle enroute to the mines of the Alaska Gold Mining Company.

A. H. LAWRY, general manager of the Montana-Tonopah Mines Co., is at Pearce, Arizona, inspecting the new mill of the Commonwealth Mining Co., a subsidiary of the Nevada company.

RICHARD B. STANFORD, formerly manager and consulting engineer for the Bonanza mine, Nicaragua, is now in New Orleans. ORVIL R. WHITAKER, of Denver, is consulting engineer for the Canadian Agency, Ltd., of New York, which has recently acquired this property.

Obituary

EUGENE A. BYRNES, a prominent patent attorney of Washington, D. C., and a charter member of the American Electrochemical Society, died on August 1, at Haven, Maine, where he had gone for his vacation.

WILLIAM R. DAVEY, of Lake City, Colorado, died at Portland, Oregon, September 11, from pneumonia, following an operation for appendicitis. He was 39 years of age, and a graduate of the Colorado School of Mines, class of 1898. For several years he had been in the federal government employ, at first in the Forest Service in Colorado, and for the past four years as a mineral inspector for the General Land Office in the First Field Division, embracing Oregon, Washington, and Idaho.

The Metal Markets

EASTERN METAL MARKETS.
(By wire from New York.)

NEW YORK, October 16.—The copper market is weak, with little or no demand. The copper stocks are generally weak and, with underlying conditions unchanged, there is no reason to expect anything more than a fractional change in the market. The London market is firm with spot and futures at £71 13s. 9d. New York quotes electrolytic at from 16.50 to 16.87, Lake 16.75 to 17, and castings 16.37 to 16.75. The lead market is weak. Ordinarily this is the busy season of the year, but the uncertainty due to the new tariff has unsettled the business to some extent. A conservative policy is being generally pursued. Zinc is weak and but little trading is reported.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

May	16.03	15.42	17.31
June	17.23	14.71	17.37

The expected effect of the Copper Producers' report in stimulating copper buying entirely failed to materialize, and the market was duller at the end of last week than it was at the beginning. On October 6 copper was being offered at 16½c. without bringing out any domestic buyers, though sales for export were made. The large producers pegged the quotation at 16½c., but metal was available at the lower figure up to January. On October 7 nothing was done ex-

cept wait for the statistics. When the figures came out buyers exhibited as little interest as before, and the situation remained unchanged. On October 10 small dealers were offering small lots at 16¼c. without doing much business. The big sellers adhered to the price of 16½c. without reporting any sales. The price in London declined, standard G. M. B. warrants closing at £71 5s. for spot and futures. The exports from New York for the week ended October 9 amounted to 5763 tons, or 8442 tons since October 1, as compared with 10,442 tons since last year. Whether this is the beginning of a decline in European consumption it is too soon to judge.

The following figures supplied by L. Vogelstein & Co., show the movements of copper in Germany from January to July, inclusive:

Imports	134,293
Exports	6,010
Consumption	128,283
Consumption during similar period of 1912.....	120,071
Imports from United States in 1913 period.....	115,349

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending	Oct. 1.....
Sept. 17.....	39.50
" 24.....	39.50
Oct. 8.....	39.50
" 15.....	39.00

June	41.30	41.00	39.75

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

1912.	1913.	1912.	1913.
Jan.	42.53	50.45	44.25
Feb.	42.96	49.07	45.80
Mch.	42.58	46.95	48.64
Apr.	43.92	49.00	50.01
May	46.05	49.10	49.92
June	46.76	45.10	49.80

Tin statistics at the beginning of October, 1913, showed many contradictory features, according to L. Vogelstein & Co. In the first place, and as the principal if not the only favorable factor, it is to be noted that the visible supply at September 30 this year is nearly 300 tons smaller than at the corresponding date of 1912, and the price £43 per ton or about 10c. per pound lower. The exact figures being 13,245 and 12,943 tons, £231 and £188 per ton in London, and 51 and 41c. per pound in New York, respectively. The net supplies were 3890 tons and deliveries 2996 tons for the nine months ended September 30 this year. While conceding that the drastic price reduction has partly if not wholly discounted the changed position, the trade is not hopeful of any permanent or extensive advance until the trend of events has taken a more favorable turn; that is, until the position begins to improve instead of uniformly getting worse as seems to be the case at present. Unfortunately, no such favorable change is in prospect, and we do not look for other than a fluctuating market over the immediate future. Meanwhile the position is not unsound.

*Ohio includes Michigan and Missouri.

The total petroleum production of the United States to the end of 1912 was 2,820,426,549 bbl., valued at \$2,338,032,130. Stocks decreased from 137,232,998 to 122,869,702 bbl. during the year. There was a total of 157,335 productive wells in the country at the end of the year. About one-third of the oil yield was used as fuel in power plants, etc., and railroads consumed 33,605,598 bbl. Imports of petroleum were valued at \$6,082,881, and exports of all kinds of oils to foreign countries totaled 1,883,479,897 gal. valued at \$124,210,382. Production of the world in 1912 was as follows:

Austria-Hungary.....	8,535,174
Canada.....	243,614
Dutch East Indies.....	10,845,624
Germany.....	995,764
Italy.....	86,286
India.....	7,116,672

United States.....	222,113,218
Other.....	250,000

Total.....351,178,236

Scotland and New South Wales produced 3,116,803 and 75,000 tons of oil shale, valued at \$4,171,174 and \$180,000, respectively.

*Abstract from advance chapter from 'Mineral Resources of the United States, 1912.'

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PRICE OF NATURAL OAS for domestic purposes in various states is as follows, in cents per 1000 cu. ft.: West Virginia, 18.12; Pennsylvania, 26.02; Ohio, 27.40; Kansas, 22.82; Oklahoma, 16.88; New York, 30.39; Indiana, 29.92; Louisiana, 22.84; Illinois, 22.85; Kentucky, 30.57; Texas, 39.73; and Alabama, 22.84 cents.

METALLURGICAL difficulties have resulted in the permanent closing of the Lancefield mine, Western Australia. The ore reserves total 200,000 tons, worth \$7.50 per ton, but the arsenic and graphite contained baffled all methods of treatment, one system alone having handled 600,000 tons yielding \$4,300,000. Highest recoveries were 80%, but gave no profits.

QUANTITIES of material handled daily at the Washoe plant of the Anaconda Copper Mining Co. are as follows: ore, 12,000 tons; lime rock, 2300 tons; coke used, 500 tons; coal for reverberatory furnaces, 500 tons; coal for power, 50 tons; and water used per minute, 35,000 gal. Men employed in and around Anaconda total 3000, with a monthly payroll of \$300,000.

MINERS employed at the South mine, Broken Hill, are mostly on contract, and during the half-year ended June 30, 1913, they averaged \$4.16 per 8-hour shift on development and stoping, and \$3.22 tramming ore and waste. The average daily attendance of underground men was 787. The cost of stope-filling was \$1.01 per cubic yard which amounts to 36c. per ton of crude ore mined.

THE Progress mine is situated at Reefton, South Island of New Zealand, and costs per ton during 1912 were as follows:

Mining	\$2.30	Crushing	\$0.05
Hoisting	0.72	Stamp milling	0.36
Transportation	0.38	Concentration (coarse)	0.15
Maintenance	0.80	Concentration (fine)	0.06
Pumping and baling... ..	0.02	Cyaniding	0.30
		Accumulating slime... ..	0.01
Total mining.....	\$4.22		
		Total milling.....	\$0.93

EXTENT OF ENRICHMENT IN DEPTH is a matter of great interest. According to J. F. Kemp, it depends primarily upon the vertical depth to which it will be admitted that descending, acidified, metal-bearing solutions, produced by the leaching of the oxidized zone by meteoric waters, may slowly diffuse themselves in the standing ground-water. Obviously, the chief reactions will take place near the ground-water level. One cannot reasonably expect the influence to extend very far. The production of oxidized and enriched ores of zinc is practically limited to a few feet above and below the water-level. Lead is very intractable, and its enrichment is practically a matter of oxidization and removal of other and more soluble associates above the water-level. The behavior of silver is a matter on which light is needed and on which there is a difference of opinion among engineers. Gold, though at first sight a comparatively insoluble metal, does yield to the solutions afforded by oxidizing pyrite, in the presence of manganese, as has been found by Emmons. To what depth, however, the slow diffusion of descending solutions would bring the enriching effects below the water-level is a question. Copper is the metal of preëminent importance in matters of secondary enrichment. Reported falling off in value as greater depths have been attained, has made the influence of this process of special importance. The appreciable decrease in copper percentages which were widely published fifteen years or so ago, regarding the Rio Tinto mines, called attention to it even at that early date.

UNDERHAND STOPING with square sets, according to J. C. Coldham, has become general in stoping the following at the Broken Hill Proprietary mine, Australia: (1) bridges of ore remaining from open stopes; (2) pillars which have generally become broken through pressure and creeps; (3) portions of the lode in which the ore is naturally broken; and (4) portions of the fire areas, where the action of the fires has caused a roasting of the ore, which has become a fine sand and mixed with the stope filling, forming a mass, the mining of which is difficult, owing to its soft, floury nature. This ground may be termed running ground. The chief advantages of the method are summarized as follows: (1) when the orebody is such that each fresh back must be caught immediately it is opened, the underhand method is superior to any method of back stoping, as the back must be held up only on the top floor of the stope, while in overhead stoping each floor presents the difficulties of a fresh back. The importance of this may be seen from the extreme case of running ground where the contract rate for top sets may amount to as much as 48c. per ton in excess of the rate for the lower sets; (2) with this method of working in vertical slices, much less back is left unsupported by filling than when working with a flat or rill face; (3) the filling cost is less when filling deep cuts than when filling flat, shallow cuts; and (4) should occasion arise, it is more convenient to fill close to the face when working out the ground in vertical slices. The method has proved itself more suitable than any other in working out bad ground.

GENERAL RULES for the prevention of accidents at the Copper Queen company's mines, in Arizona, include the following for underground work: 1. As all mining work is hazardous, extra care should be taken not only for your own safety, but for the safety of men working with you. 2. Watch for danger signals; they are often unnoticed if there is not sufficient light. 3. Every manhole and place of refuge shall be kept constantly clear, and no refuse shall be placed therein, and no person shall in any way prevent access thereto. 4. The general condition of the timbering in the mine shall be safe. The men shall take all the necessary precautions to insure the safety of the timber in the working places. 5. In all stopes where square sets are used, it shall be the duty of men working in stopes to see that the floors are properly centred on the caps, particularly after blasting, and spiked wherever deemed necessary. 6. When working in heavy or untimbered ground, care should be taken that there is plenty of room for a quick exit. All obstructions such as cars, wheelbarrows, etc., should be moved out of the way. 7. Existing winzes opening directly from the floor of the drift or stope must be kept covered by a substantial hatch, or planking, except when in use, at which time the passage to persons other than those working at the winze shall be barred off by a substantial rail across the roads of access to the openings. 8. The miners shall be responsible for the safety of the roof and walls of their working places. 9. In mining, care must be taken in approaching workings thought to be filled with water, and the bore holes must be kept at least 20 ft. in advance of the drive. 10. Planking over sumps and ditches must be kept secure. 11. No candle or lamp shall be left burning in a mine when the person using the candle or lamp departs from his work for the day. Sconces must positively be used, except when candlesticks or carbide lamps are employed. Lights must be placed so that timber cannot catch fire. 12. Employees shall, as soon as discovered, inform the foreman or shift boss of the unsafe condition of any working place. 13. Be sure that chutes are protected so that men cannot fall into them. 14. Men are strictly forbidden to carry tools upon their shoulders in any drifts where electric wires are installed. It is very dangerous and may result in death. 15. Two openings to surface are provided by law, except in the case of mines that are being opened. 16. Men should learn the different openings from their place of work, and their attention is called to signs at the intersection of drifts which direct them to shafts or outlets.

Monthly Copper Production

AHMEEK COPPER MINING CO., Kearsarge, Michigan. \$1,250,000 in \$25 shares; 24,796 shares owned by Calumet & Hecla; 1800-ton mill at Hubbell; concentrate smelted by Calumet & Hecla smelter.

Month.	Pounds.	Month.	Pounds.
April	1,503,535	June	1,281,960
May	1,061,995	July	1,020,500

ALLOUEZ MINING CO., Allouez, Michigan. \$2,500,000 in \$25 shares; controlled by the Calumet & Hecla, which owns 43,000 shares and \$250,000 in notes of the Company; ore is milled by the Lake Milling, Smelting & Refining Co., in which the Allouez owns a half interest.

Month.	Pounds.	Month.	Pounds.
April	603,210	June	556,675
May	475,535	July	398,565

ANACONDA COPPER MINING CO., Butte, Montana. \$108,312,500 in \$25 shares; controlled through Amalgamated Copper Co. by Thos. F. Cole, J. D. Ryan, and Standard Oil interests; 10,000-ton concentrator and smelter at Anaconda; 5000-ton concentrator and smelter at Great Falls, Mont.; also 70-ton electrolytic refining plant at Great Falls. Production figures include copper from all companies which ship custom ore to Anaconda smelters.

Month.	Pounds.	Month.	Pounds.
April	23,800,000	July	21,181,000
May	25,600,000	August	22,500,000

REGARDLESS of the unsettled conditions in Mexico and the paralysis of business which is claimed, the Department of Commerce reports that the trade conditions between that country and the United States during the past fiscal year are the best on record. The figures compiled show the imports from Mexico to have increased by \$11,500,000, while the exports to that country increased \$1,750,000.

THE story of the ninety-nine per cent matte, which was reported to have been 'frozen' in a furnace of the Arizona Copper Company, and would require from five to six months to recover, is worthy of the pen of some of our consular representatives, who can estimate the cost of several hundreds of miles of railway construction to the dollar and perform technical feats equally as wonderful as the making of a ninety-nine per cent matte.

YES, gentle reader, 'banket' is an obsolete form of banquet and it may be that the progenator of this perfectly good geological term saw in the African deposits the possibility of a sumptuous repast when he dubbed them bankets. However, the origin of the term is Dutch, and its application to the deposits of the Rand and Rhodesia is due to their likeness in appearance to an almond sweetmeat which the Boer school-boy calls by this name.

STATE GEOLOGISTS of Missouri, Iowa, Oklahoma, Arkansas, Tennessee, Ohio, Indiana, and Illinois, with Mr. C. D. White and Mr. W. H. Heron, of the United States Geological Survey, and Mr. Stuart Weller, of the University of Chicago, met at St. Louis recently at a dinner followed by a two days field conference in Ste. Genevieve county, Missouri, at which problems in geologic correlation were discussed. So fruitful was the conference that future meetings are planned and a permanent executive committee has been chosen, with Mr. H. A. Buehler as chairman.

THE protest against the revision of the mining law that we reprinted last week from the *Bisbee Daily Review* was, we find, but part of an article written by Mr. Russell L. Dunn and originally printed in the *Mining and Engineering World*. We gladly make acknowledgment to Mr. Dunn and to our Chicago contemporary and regret that the absence of a credit line in the *Review* misled us. Mr. Dunn was at one time a member of the editorial staff of the *Mining and Scientific Press*, and while we do not at all agree with his conclusions, we recognize freely the skill with which he has presented his argu-

ment. In this issue we present something on the other side from Mr. George Otis Smith, the director of the United States Geological Survey, who writes forcefully from the basis of wide observation and much study. We have other papers on the subject in hand and are glad to believe that the time is ripe for a real revision of the mining law.

Progress in Fuel Utilization

The community of interest in the field of metallurgy was well shown at the meeting of the Iron and Steel Section of the American Institute of Mining Engineers in New York last week. During the session a number of notable papers upon the use of powdered coal as fuel, and the recovery of waste heat from metallurgical furnaces were read and discussed at some length, and the results attained in the field of zinc and copper metallurgy were presented and listened to with interest by the steel metallurgists. Curiously enough, three of the papers had almost identical titles, though Messrs. R. K. Meade, H. R. Barnhurst, and W. S. Quigley treated the general subject of the use of powdered coal as fuel from slightly different aspects. These were preceded by two papers on the generation of steam by the waste heat of furnaces, read by Mr. G. C. Stone and by the secretary for Mr. F. Peter, professor at Leoben.

The present importance of the use of pulverized coal as fuel is illustrated by Mr. Barnhurst's estimate that 10,000 tons of coal in this form is burned daily in the cement industry alone. The development of direct-firing with coal dust has indeed advanced almost *pari passu* with the growth of the output of cement, the large quantity of coal used in the production of so cheap a commodity making necessary the use of fuel in a form which permits more efficient use of its heat content than is possible in any system of indirect firing. To a less extent, it has been applied to other fields of work, and its present use at the smelter of the Canadian Copper Company and the earlier experiments at the Highland Boy plant and at Cananea are well known to many of our readers.

The difficulties in the early work in all fields arose from the presence of moisture in the coal, insufficient grinding, and the attempt to use unsuitable types of coal. It is now possible to use any long-flame coal which contains over 25 per cent of volatile hydrocarbons, and coal containing as much as 25 per cent ash has been used in cement burning. In smelting, so high an ash content would not be permissible, especially in copper treatment, for if the ash is fusible it tends to clog the flues and waste-heat boilers, while if it is infusible it is an unwelcome addition to the already highly silicious charge on the hearth. Before pulverizing, the coal must be thoroughly dried. In addition to the bad effect of moisture on pulverizing and injecting the coal, each per cent of moisture in the fuel corresponds to a decrease of 52 degrees Fahrenheit in the temperature attainable in the furnace; a decrease which cannot be overcome by burning additional fuel. This bad effect is accentuated by the fact that only part of the heat is utilized in the furnace; thus if the

powdered coal contains five per cent moisture, the temperature in the zone of combustion is 1500, and the temperature of the outgoing gases is 600 degrees—the heat wasted in raising the water to the temperature of the escaping gases corresponds to nearly ten per cent of the total heat value of the fuel. Standard practice requires the grinding of the pulverized coal so that ninety-five per cent will pass 100 mesh and eighty-five per cent through 200 mesh.

The aim in coal pulverizing is to make a maximum of what the millman used to call 'slime,' namely, material too finely divided to permit measurement. Various types of mills have proved satisfactory; ball-mills, various tube-mills, Raymond, and Griffin mills. Certain types of these permit the burning of coal as fast as it is ground; in others it is caught in storage-bins. The ground coal is not explosive unless it is so stirred up as to form an explosive mixture with air.

In ordinary practice the coal is blown into the furnace by the use of twenty-five per cent of air, furnished either by a fan or by blowers which deliver it at higher pressures, the fan being preferred as cheaper. If a larger quantity of air is used, the flame becomes shorter, since the deflagration of the coal immediately in front of the nozzle is thus favored. The length of the flame attained depends, therefore, on the character of the coal, the amount of air used in its injection, and the draft. Regulation of the length of the flame is best done by manipulating the draft. It is, of course, necessary to admit an excess of air over that required for combustion, and the temperature attained can easily be controlled by regulating the amount of fuel admitted. The convenience and economy of this method of firing is leading to its increased use in open-hearth and puddling furnaces, and, within the limitations of local conditions, is likely to lead to its increased use in reverberatory copper smelting.

The high temperature of the gases escaping from such furnaces makes it especially desirable that some of their contained heat shall be recovered. This is commonly attained by the use of regenerators, but the gases escaping from these still contain recoverable heat. Unless their temperature exceeds 300 degrees Centigrade there is no economy in attempting to recover this heat, since the temperature difference between the gases and the steam generated is so small as to make the transfer of heat from the one to the other impracticably slow. The lowest practicable limit is perhaps attained at the Palmerton, Pennsylvania, plant of the New Jersey Zinc Company, described by Mr. Stone, where gases (at 450°C.) escaping from the spelter furnaces are utilized in a battery of return-tubular boilers which furnish the steam required for the gas producers. It is there found that three horse-power can be recovered in the waste-heat boiler for each ton of coal gasified in the producers, without interfering with the results attained in the spelter furnaces. With reverberatory copper-smelting furnaces the use of waste-heat boilers is standard practice, and the important paper by Mr. S. S. Sorensen, published in our issue of October 11, is of especial value, since it gives the comparative results attained by two different types

of boilers, and thus contributes greatly to that more exact knowledge of this subject which is much to be desired.

The Copper Situation

Publication of the September statistics of refinery output and deliveries of copper to the trade renders possible some interesting comparisons. Production during the nine months of 1913 has averaged a little over 134 million pounds of copper monthly, as compared with deliveries of nearly 143 million. This compares with an average of a little less than 132 millions average monthly refinery output for 1912 and average deliveries of 130 million. The increase of output has therefore been about $2\frac{1}{2}$ million pounds per month, and of deliveries 12 million. The excess of average monthly output over deliveries of 1,320,000 pounds during 1912 has been converted into a monthly deficit of over $8\frac{1}{2}$ millions. It is interesting to notice that the increase in output approximately corresponds to the increase in domestic deliveries, which are almost 2 million pounds greater for the average of the nine months. Deliveries for export, on the other hand, have averaged nearly 10 million pounds per month more than during 1912. The generally accepted explanation of this is that European stocks were allowed to run down to subnormal figures last year because of the impending outbreak of the Balkans, and that this year, in expectation of a speedy return of settled conditions, European consumers have been refilling their yards, doing their buying at the low points in the market price of the metal. Since exports and domestic deliveries are about equal in amount, it is evident that the increase in exports is greatly in excess of the natural growth of consumption unless it is assumed that the increase of domestic deliveries is less than normal. This may possibly be the case, for trade generally has been awaiting the passage of the new tariff act, questioning what its effect will be. It is natural that under such circumstances manufacturers, who are the immediate consumers of copper, should wish to meet the new conditions with as small stocks of unsold goods as is compatible with the safe conduct of business. European manufacturers, on the other hand, generally expect an increase in their business in this country and are stocking up to reap the cream of the profits before prices reach their new level of adjustment. The present situation, therefore, appears on the face of it, to be a natural rather than an adventitious one. It follows, then, that next year may be expected to show a relatively larger increase in domestic consumption and a relative slackening of the demand for export, the average of the two corresponding to the normal growth of consumption.

In the interest of completeness it must be added that there are those who doubt the validity of inferences drawn from the producers' statistics, which constitute only what may be called a cross-section through the copper trade at one point. The copper which has been produced by the smelters but which has not reached the refineries, the metal in the yards

of consumers, and copper in the hands of others than consumers all are unknown quantities which render exact equations insoluble. It is amusing to note that the suspicion is international in character, consumers here being unable to understand the reported decreases in European stocks simultaneously with record-breaking exports to Europe, while a correspondent of the London *Financial Times* has recently written to that journal to express his view that "the optimistic reports which have been circulated of late are manifestly inspired" and that to him "it would appear to be a recurrence of the game that has been so often played upon England by the Americans." Like our police investigations, the matter will doubtless eventually resolve itself into a fruitless search for the 'man higher up.'

The most interesting point is whether the abnormally low figure to which stocks of copper have attained constitutes any menace to stable conditions, and whether a sudden increase in the domestic demand may be expected to send prices soaring. Any expression on this matter can only be one of personal opinion; an opinion, moreover, that, like the railway time-tables, is subject to change without notice, since it involves so many elements that are necessarily unknowable. The past six months have shown that consumers can remain out of the market for unexpectedly long periods, and if we get over the remainder of the year safely it will have been demonstrated that stable conditions can be maintained on much smaller stocks of the metal than was previously supposed. This will be for the advantage of everyone, for the decrease of American stocks since February of nearly 100 million pounds will represent the doing away of an unnecessary insurance charge. For example, if a merchant doing \$100,000 in business per month found it feasible, through improved conditions, to reduce the stock on his shelves by \$60,000 and still do business successfully, his profits would obviously benefit by the decrease in carrying charges on his stock.

The flexibility of mine and refinery production at present in the United States is probably greater than is generally supposed. The September refinery output was only 3 million pounds less than the average for the past nine months, although the output of the Lake Superior district is estimated to have been 11 million pounds below normal. The 'copper in transit' of the large companies is always considerable in amount. Thus the Utah Copper reported about 15 million pounds 'in transit' on January 1 last, following a period of disturbed conditions in which its output had been reduced to only 4 million pounds per month. The Chino, then producing about $3\frac{1}{2}$ million per month, similarly reported nearly 11 million pounds of copper in transit. What inflexibility exists is due rather to the refineries, where the output of electrolytic tanks is not amenable to abrupt increases and decreases. Considering the industry as a whole and comparing the natural growth of consumption with the increase in output of many important properties and the impending output of large new mines, there seems no reason to expect any increase in what we have previously designated as the normal price of copper.

Plain Talk on Land Law Revision

By GEORGE OTIS SMITH

*Whatever the forum selected, public discussion in America tends to evoke more language than ideas. Most of us err in this way, and we all feel the influence when we think aloud before our assembled fellows, with the result that we sometimes strive less for common sense than for uncommon sound. Plain ideas are dressed up in borrowed or imported finery with all the tender care that a fond mother lavishes upon her little girl going to a first party, so that too often the practical man who knows the work-a-day world at first hand delivers an address conspicuous for the elegant words which completely envelop and conceal plain facts and solid opinions that deserve more appropriate treatment.

Plain talk is more becoming than oratory to a time like the present, when the signs point to large changes in the world of business and industry. The members of the American Mining Congress are men connected in one way or another with the business of taking out of the ground things that are useful. Mining is a productive industry of the first rank, and it is plain that our mines are fairly essential to human welfare. Here, then, if anywhere, do the problems of common interest to both the public and the mining industry deserve to be discussed in plain language that the everyday man uses and understands.

Mining on Public Lands

To consider now perhaps the most important matter in which this body is particularly interested, namely, the federal legislation needed to promote mining on public lands, it is imperative to recognize certain ideas that have won large popular support, if not adoption by the majority, especially as these ideas have never been written into our archaic mining laws. Some of these principles are: that the public possesses greater rights than any individual or corporation; private enterprise must be subordinated to the public good; big business is not necessarily either vicious or unfriendly to public interest, but big business more than small business is in need of a strong control by the people; the day of big business in the sense of unnatural and unrestrained monopoly and special privilege is passing; effective inspection and intelligent regulation of industry by the people's representatives will increase; the bright light of publicity should and will shine on the inner workings of all private business which either touches or controls the production and distribution of the necessities of life, and publicity is logically the first step in regulation by the people. All of these propositions must, I believe, be accepted as premises in the formulation of any new mining statutes whose purpose is to provide at all adequately for the present and the future.

To come now to the question of what is needed in mineral land legislation, a plain statement of

facts will help. Legislative programs too often resemble the hotel bill of fare which the average citizen has to ask the waiter to translate. In my opinion, we want these laws for the coal and oil and phosphate lands first of all for the sake of the citizens who wish to use the mineral product from these lands. Not that the other citizens are not to be served by the new legislation, but as consumers everyone is concerned with prices, and to benefit the many as well as the few, legislation must favor low costs. It should therefore put down as the first essential of mineral land legislation that no provision in the law should place any unnecessary charge, burden, or operating cost upon the operator. Accordingly, no royalty should be imposed with the primary purpose of revenue. The consumer will surely pay the tax, if the charge paid to the Government landlord is imposed for other than purposes of administration and of control in the interest of the consumer. The most recently issued water-power permits provide that the federal government shall receive a royalty which varies directly with the square of the average price paid by the public for the electric current. The less the consumer pays, the less the government landlord receives.

Risks and Uncertainties of Mining

A large burden which the mining industry now has to bear and which should be lightened is that made up of the various risks and uncertainties that attend it. In mining there is guesswork enough of Nature's own making to give the industry all the speculative flavor it needs. As I have pointed out in a paper published this month by the American Institute of Mining Engineers, any investment risk increases both cost and selling price, and whatever the origin of that risk, the ultimate consumer will find that he pays the carrying charge. For this reason, in order to lower the cost of coal, I favor a leasing law rather than the present method of selling government coal lands at an appraised valuation. Any scheme of selling an undeveloped resource involves uncertainties in valuation, and the risk thus created is liberally discounted by the operator—necessarily and properly, I may add, for his own protection, but the public pays the bill. Even more important is the feature that under lease the operator is relieved from all the burden of land investment.

The Oil Prospector

Other illustrations of uncertainties that can and should be removed will occur to those of you who are more familiar with mining than I am. I may mention, however, the unnecessary risk that has been forced on the oil prospector in the possibility of having his claim jumped by a more resourceful driller. Absolute protection during a proper period of exploration should be made a feature of every mining law. Another unnecessary and very costly

*Address before the American Mining Congress, Philadelphia, Pennsylvania, October 22, 1913.

risk has been mentioned by H. V. Winchell—the extralateral right embodied in our lode law. Mere mention of the 'apex' brings to mind litigation that has wasted the substance of Western mine-owners like a plague, many a long continued suit being almost as disastrous to the successful litigant as to his opponent. Even where lawsuits have been avoided, fear of them has constituted an element of risk that has surely found its place in the financing and operating of a mine on a lode claim.

Inducements to Development

Second in importance only to this matter of protecting the mineral producer from unnecessary operating costs is the need of offering to the developer of an unused resource an inducement commensurate with the hazardous or speculative character of his undertaking. This cuts both ways. To promote development, mining laws should attract the men having the knowledge and capital necessary to engage in the business of mining, but it does not follow that mining on the public domain should be set up like a public lottery, with the same big prizes for all comers whatever the risk taken. Too often in the past the practice has been for the majority of locators to sit by and watch a few real miners test out the ground, when if a strike was made, these hangers-on at once had valuable claims to sell. The 'wild-catter' who in his compliance with both spirit and letter of the law has risked his last cent in discovering oil, has received no more land from the government than the school-teachers, drygoods clerks, and barkeepers whose names have decorated the paper locations for miles about. The present system has passed out too many large premiums to those who did not even take a chance—at least their stake was only a picayune compared with the bonanza prize. This means unearned increment in large amounts, and in the end the consumer pays for it. To continue this kind of a mineral land lottery is bad economics. On the other hand, however, any law for the disposition of mineral land, whether by lease or not, should provide large rewards for the real prospector and the wild-catter, who so often stake their all against an uncertain and secretive Nature; when they lose they have no redress, and when they win, their discoveries usually add more to the nation's wealth than to their own pockets. They deserve to be in the preferred class; but why offer the same reward to the taggers-on, who simply rush in to grab a share in a sure thing?

Rights of the Individual

A third side of this proposition is the question of the inalienable right of each citizen to his share of the nation's mineral wealth. This vague right has possibly come to appear more definite and substantial in recent years because of magazine statistics setting forth our per capita share in the wondrous wealth represented by Alaskan coal, but even writers with much more information and sense also speak of the unconditional free grant of valuable minerals as the something-for-nothing that goes with American citizenship. There is more reason in figuring the citizen's right and interest in any unde-

veloped minerals as a double one: (1) that measured by the possibility of the mineral being mined and thus made useful at a cost to him that shall not be unnecessarily high; and (2) his right to an equal chance to undertake mining within the limits of his own ability. He has absolutely no right to a speculative profit from public mineral lands, and his profit as a producer should be measured by his own productive contribution. It follows that it is absurd to talk about free or unconditional grants of mineral land as a perquisite of American citizenship. The privilege should pass only on condition of productive labor. The real intent, and in fact the stated purpose, of our old mining statutes is development which means use, and some attempt has been made in each law to make that the condition of occupancy of mineral land. This principle seems absolutely right, and new legislation needs only to enforce the idea best set forth by E. B. Kirby at the Tonopah meeting of the Mining Congress—"Dig or get off the claim." As I remember his plain talk at that time, we do not need to blame either Congress or the Land Office for the paralysis of mining districts, but need only to look around and see the idle claims whose owners are waiting for something to turn up and somebody else to turn it up. The law needs to offer opportunity only to the mineral entryman who uses that opportunity. Equal opportunity is more theoretical than practical with men who are unequal in capacity and purpose. The use the citizen is to make of the land should be the measure of his right and privileges.

Area of Mineral Claims

In the matter of acreages, the various mineral land laws present some curious features. The law-maker appears to have harked back to the homestead idea, but it takes little experience to show that 160 acres, which will provide a home on the land, counts for little, for instance, in the opening of a coal mine that will have a half-million ton annual output and involves a half-million dollar investment. These legal obstacles naturally resulted in the creation of a class of dummy entrymen and speculative middlemen who grabbed government land for the purpose of selling it to the bona fide coal operators. Experience shows that it is a purposeless and bad economic policy for the government to dispose of such mineral lands in small lots simply to give everyone his chance. Let the particular use to which the land is to be put determine the appropriate acreage, and give the man who is to put the land to that use the chance to deal directly with the federal owner, and not force him to pay an idle middleman's profit.

With these purposes in mind, and with due regard for changed conditions both in the mining industry and in public opinion, how can federal legislation meet the nation's need? As a summary, I can do no better than express my conception of the main essentials of a new mining code, following in general the analysis of the whole problem recently outlined by the special committee of the Mining and Metallurgical Society of America:

1. Land classification is the duty of the landlord, private or federal, as a preliminary to the disposi-

tion of any or all of the natural resources the land contains. Separation of surface and mineral rights follows as the logical result of classification, wherever there is any reason to consider that there may be more than one estate in the land.

2. While the title to the surface of lands suitable for agricultural use should be granted in fee, thus continuing the wise policy of encouraging home making, public interest, and the need of protecting the consumer against private monopoly are believed to justify the retention in the government of such surface resources as timber and water-power, because their cheapest and fullest use is best secured by operation in large units. Even more important is the reservation by the government, at the time that the surface patent is granted, of all mineral wealth beneath the surface for separate disposition, under mineral land laws. In private transfers of land the reservation of mineral rights is becoming more and more the common practice.

3. The possessory title to the mineral should be retained in the government, not for the purpose of asserting any theory of 'sovereign patrimony' or 'regalian right,' but simply as a practical method of assuring development under the best conditions. Let us regard the federal government as a trustee rather than as a sovereign landlord, and the idea and purpose of proprietorship by the people becomes more easily understood.

Leasing of Mineral Lands

The application of the lease idea to the mining of precious metals, while logical in certain respects, is not at all of comparable importance with its application to what have been termed 'public utility' mineral resources, such as coal, petroleum, phosphate, and potash. The utilization of this class of resources is of prime importance and questions relating to their disposition have a practical rather than an academic interest. Leasehold has the advantage over permanent alienation in that it allows the government to exercise continued control in the public interest. Such control is essential in order to promote use and discourage speculative non-use, to prevent control of large land holdings by powerful corporations for such monopolization as works to the detriment of the consumer, and also to permit and even to promote consolidation of holdings and centralization of operation where large units are favorable to the public interest. To work out control of this type, the mining law should provide for prospecting permits that will give exclusive occupancy during short periods—long enough, however, for full exploration—under terms and conditions whose sole purpose should be to insure that only bona-fide prospectors will enter the land and that they will do purposeful work. The annual assessment farce has had a long enough run. The prospecting permit will ripen into a lease whenever the results of exploration justify the operation of the property on a producing basis. Where the proof of coal or oil or other mineral substance in commercial quantity is a discovery of the type termed 'wild-cat' in the case of oil, the prospector rendering such service to the industry and to the public should receive his lease upon purely nominal terms.

No bonus or rent should be exacted from the lessee, except possibly rent during any period of temporary cessation of production, and that simply as a means of discouraging non-use. The royalty on the product, whether figured on quantity or value of output or on net returns, should be no higher than is necessitated by royalties or other charges prevailing for similar products under private leases in the same locality. Wherever the price to the consumer could be directly affected by the royalty to the people's trustee, the royalty should be lowered to a nominal figure.

The essential features of the lease should be conditions enforcing full and continuous use, economy, and safety of operation, and control of occupancy. Transfers should not be prohibited, but simply made subject to approval by the people's representative. If in any region large units of production are seen to favor lower costs and longer lived industry, all for the public good, consolidation of holdings should be encouraged and transfers of leases permitted; but if the purpose of large holdings is monopolization in order to curtail production and raise prices, transfers to that end should be denied the executive approval necessary to make them effective.

Public Control

As I look ahead, and not so far ahead either, I believe I see the following propositions stand out plainly in the future status of mining on the public lands. The mining men, like the rest of the people, will see that this big productive business belongs in the public-service class; because its products are so largely necessities of life, the mining industry will be regulated by the people; the control of public mineral lands will be exercised largely through a leasing system, simply because in this way the public owner and private operator can best co-operate, and the purpose of this sympathetic co-operation will be to lower costs of production in order to permit reasonable prices to the consumer, and at the same time provide fair wages to the mine worker and adequate profits to the capitalist and operator—that will be public control, but not Socialism.

Diamond output of the Union of South Africa during the first half of 1913 was as follows:

	Carats.	Value.
Transvaal (Premier and others).....	1,081,995	£1,482,510
Cape Colony (De Beers at Kimberley).....	1,250,775	3,635,282
Orange Free State	273,560	839,834
Total	2,606,330	£5,957,626

The De Beers company will celebrate its twenty-fifth anniversary by granting certain holidays on full pay to its employees.

Mine-rescue work is receiving deserved attention in Canada as well as in the United States. In addition to the rescue and training stations at Blairmore and Lettisbridge opened in 1912, there are now stations at Kipp and Edmonton and a mine-rescue car furnished by the Canadian Pacific. All these are equipped with Proto rescue apparatus, oxygen pumps, oxygen reviving apparatus, electric hand lamps, and other equipment.

Blast-Hole Drilling in Open-Pit Copper Mining

*At Copper Flat, Nevada, the Nevada Consolidated Copper Co. is mining copper ores with steam-shovels in open pits. This mine is classed with the so-called 'porphyries' such as those at Bingham, Utah, and Santa Rita, New Mexico. The mines of this character have large orebodies containing from 40,000,000 to 400,000,000 tons of copper ore, with a copper content of 1 to 3%. The ore is capped by barren material, the ratio of which to the ore is so small that open-pit mining can be carried on more economically than underground mining.

The Copper Flat Orebody

The Copper Flat orebody covers an area about 3600 ft. in length and 1200 ft. in width, and has an

had to be blasted before the steam-shovels could dig it. On account of the height of the banks and the volume of the material handled, either 'gopher' holes or blast holes must be used in order to blast the ground and keep pace with the shovels. 'Gopher holes' are adits driven into the base of a bank with a cross-cut on each side at the face, forming a T. The explosives are placed in the cross-cuts, tamped, and exploded. A 'gopher hole' is expensive to drive and cannot be efficiently tamped, necessitating the use of additional explosives. Blast holes are put down vertically through the bank and are about six inches in diameter. These are chambered at the bottom with explosives to admit a sufficient charge to break the ground. Blast holes are quickly and

STEAM-SHOVELS AT ELY.

average thickness of about 220 ft. The overburden has an average thickness of about 100 ft. The ore consists of chalcopyrite, chalcocite, and pyrite disseminated through a highly altered porphyry. The stripping is a thoroughly leached and highly altered porphyry.

Seven 95-ton and one 70-ton Bucyrus steam-shovels are used to remove the overburden and mine the ore. The shovels operate on benches which are usually 50 ft. apart vertically, and are about 50 ft. in width. The ore is loaded into Ingolsby ore cars of 120,000 lb. capacity. Eighteen-yard Oliver side-dump cars are used to haul the stripping to the various dumps. Both the ore and dump cars are hauled by 65-ton, 6-wheel, saddle-tank locomotives. There are twelve locomotives of this class in use around the pits. Five 85-ton locomotives are used for the transportation of the ore to the smelter, a distance of 23 miles by rail.

During the calendar year of 1912 a total of 3,981,221 cu. yd. of ore and waste was excavated by the steam-shovels. Practically all of this material

cheaply drilled, and can be well tamped. To blast the material excavated in 1912, 2306 holes, having a total footage of 64,846, were drilled in ore, and 2226 holes, aggregating 83,263 ft., were drilled in stripping, or a grand total of 4532 holes, and 148,109 ft. Of these, but two holes, amounting to 110 ft., were drilled which could not be used.

Blast Holes

All blast holes are drilled with eight No. 5 and one No. 3 Keystone churn-drills. These are all traction, cog-hoist drills. The drills have been remodeled slightly to suit local conditions. Jars are seldom required, consequently the strings of tools are shorter than ordinarily. For this reason a shorter mast is used, thereby lowering the centre of gravity. When moving from one hole to drill another the mast is left up and the lower centre of gravity makes the drill less liable to tip on rough ground. All operating rods have been changed to levers and are put upon the inside of the bed instead of outside. The walking beams have been reinforced, and the spudding wheels on the beam are attached to steel I-beams. The material in several other parts has been made

*From Keystone Drill Magazine, and Colorado School of Mines Magazine.

specially of a cast steel instead of cast iron, to withstand the rough usage to which they are at times subjected. Probably many of the alterations would be unnecessary if more experienced drillers were employed. Many of the drillers have not run a drill more than six or eight months, yet they drill as many feet of hole each shift as some who have drilled for years.

Each drill has the following equipment:

- 200 ft. of 2-in. manila cable.
- 150 to 160 ft. of $\frac{3}{8}$ -in. wire sand line.
 - 1 standard Keystone rope socket.
 - 1 4-in. by 20 ft. drill stem.
 - 1 $5\frac{5}{8}$ -in. No. 100 'Mother Hubbard' bit.
 - 1 12-ft. sand pump (this is made from $4\frac{1}{4}$ -in. casing at the shops at Copper Flat).
 - 1 10-in. Keystone steam-driven blower.
 - 1 forge, consisting of a pipe 2 by 36 in. and a wood box 32 by 36 inches.
 - 1 right hand tool wrench for $3\frac{1}{2}$ -in. squares.
 - 1 left hand tool wrench for $3\frac{1}{2}$ -in. squares.
 - 1 single acting floor jack and circle.
 - 2 No. 6 Barrett lever hoisting jacks.
 - 1 spectacles.
 - 1 anvil billet and block (this consists of a piece of 75-lb. rail one foot long, spiked to a 2 by 12-in. plank).
 - 3 to 7 50-gal. barrels (3 are used in summer and 7 in winter).
 - 2 gasoline torches.
 - 2 16-lb. sledge hammers.
 - 1 set small tools, such as machinists' hammers, wrenches, and files.
- Small repair parts are also usually kept on hand, such as extra water glasses, gaskets, and pipe fittings.

Drilling Cable

The best length of drilling cable to use is 200 ft. At least 125 ft. are needed if the mast is to be lowered or raised. The rope will wear most where it is in contact with the spudding pulleys and sheave pulley, and in time must be spliced. Three splices will shorten the rope about 40 ft. After a rope has been worn out there is about 60 ft. of good rope left on the drum. Generally this 60 ft. can be spliced on to a rope having three or four splices, making a practically new rope for that drill. The other drill receives a new cable. By careful manipulation much rope can be saved in this way, and 200-ft. lengths are best suited for this purpose.

Bituminous coal is used under the boilers, and is mined at Castle Gate and Clear Creek, Utah. Water is delivered to the drills by pipe-lines from springs eight miles distant.

The drilling crew consists of one driller and one tool dresser. A foreigner, known as the coal boy, supplies two drills with coal from piles placed about every 100 ft. along the bench, and he also shovels the coal from standard coal cars to make new piles.

The drills are operated for two shifts of $10\frac{1}{2}$ hours each in every 24 hours. The day shift starts to work at 7 a.m. and at 12 noon shut down for lunch. Work is resumed at 12:30 p.m., and continues until 6 p.m. The night shift starts at 7 p.m. and follows the same schedule as the day shift.

All blast holes are drilled to a depth of 3 to 5 ft. below grade, that is, a hole of 55 ft. in depth is drilled for a bank 50 ft. in height. This removes all danger of the steam-shovels encountering unbroken rock. The holes are spaced about two-thirds of their depth apart. The slopes of the banks average 45° , thus the edge is a distance equal to the height of the bank back from the toe below. Holes for a bank 50 ft. in height are drilled to a depth of 55 ft., are spaced about 37 ft. apart, and are put as close to the upper edge as they can be conveniently drilled; generally about 10 ft. from the edge, or 60 ft. back from the base.

Method of Drilling

After a drill has completed a hole and moved to the next spot, the rear wheels are made as nearly level transversely as possible by running one wheel up on blocking if necessary. Usually blocking is not needed, but occasionally a rough piece of ground is encountered. The wheels are then blocked to prevent the drill from moving and the traction pin is removed. Two track jacks are placed beneath the front end of the bed, and are used to relieve the front wheels of the weight they usually support, also to level the front end of the drill transversely. Transverse leveling is imperative in order to keep the belt on the pulleys while the machine is running. If it is possible to drill at all, no attention is paid to longitudinal leveling. Drills are sometimes operated with the tools hanging almost to the end of the A-frame tool guide, and, again, with scarcely any room between them and the front of the machine. It is well, however, to have at least $2\frac{1}{2}$ ft. between the front of the drill and the tools. It is well to remember, in blast-hole drilling, that much valuable time may be lost in attempting to level a drill longitudinally. A 4-ft. piece of $7\frac{5}{8}$ -in. casing is used to guide the tools when drilling is started. This has two coils of old 2-in. drilling cable wrapped about it to prevent it from sinking into the hole, also to furnish a hold in removing it after the hole is finished. This short piece of casing is locally known as a 'conductor.' As mentioned above, the ground is blasted from 3 to 5 ft. below grade, so, for a few feet, the holes are drilled in broken ground. The 'conductor' keeps this broken ground from falling into the hole. Until the hole is about 4 or 5 ft. deep the drill must be run relatively slowly, but, below this depth, it is run at a speed of about 58 drops per minute. The hole is baled out every $2\frac{1}{2}$ or 3 ft. and the sludge is allowed to run down the bank below. After the hole is completed the tools are pulled up as far as possible, and are tied to the bed of the machine to prevent them from swinging while the drill is moving. The dart of the bailer is tied to the rope on the conductor and the conductor is pulled out of the hole. The bailer, or sand pump, is hauled up into the A frame, which prevents it from swinging enough to do any damage. The track jacks are removed, the traction pin is put in place, the blocks removed from the wheels and the drill is moved to the next spot.

When it is necessary to move a drill from one bench to another, a considerable distance, or from, or to, a place difficult of access, a locomotive crane

of 30-ton capacity is used. Three chains of proper length are used to take a hold on the drill; one is attached just above the front axle and the other two are attached to the two rear wheels. The mast is not lowered, nor are the tools taken off the machine; the fire is not drawn and the boiler is not blown out. In fact, the machine is ready for work as it is loaded upon a flat car. A barrel of water is put in the bed of the drill and all other equipment is put upon the flat car. When the drill is unloaded it simply moves to its place and starts drilling. The barrel of water is used until a pipe line is laid to the drill, so no time is lost after the drill is placed upon the ground.

Moving the Drill

Formerly, all moving was done by preparing roads

August, 1912, a series of holes 15 ft. deep were drilled by one drill, aggregating 2745 feet.

A working steam pressure of 100 lb. per square inch is used on all drills. The consumption of coal amounts to 600 lb. per shift. Twelve 50-gal. barrels of water will furnish the boiler and the drill-hole one shift. The following lubricants are required: $\frac{1}{2}$ pint engine oil, 1 pint valve oil, $\frac{5}{7}$ lb. cup grease per shift; $\frac{1}{2}$ gal. of gasoline will furnish illumination for one night.

The drills receive harder usage than that for which they are designed, and more or less repairs and renewals are necessary on that account. The use of the crane in moving has materially reduced repairs. By carefully noting the parts which break most frequently, and either changing the material

A BENCH AT ELY, SHOWING DRILLS AND STEAM-SHOVELS.

and running the drill on its own power. The advantages of moving a machine with the crane are that much time is saved in moving, alone; three men besides the driller and tool dresser can move the drill with the crane, whereas at least ten men are required to make roads and move equipment, otherwise. Frequently when moving a drill under its own power the drill has to travel a considerable distance along a track, and the rear wheels split many of the ties in so doing. The machine is jolted and strained appreciably, and the track is also tied up, thereby tying up a steam-shovel. If it is absolutely necessary to move a drill by its power, the tools are tied underneath the drill and dragged along the ground. A barrel of water is put in the bed of the machine, and the balance of the equipment is generally moved on a push car.

The average amount of hole drilled during a shift of $10\frac{1}{2}$ hours is 60 ft. William Gibson now holds the local record of seven holes 25 ft. in depth, drilled in one shift. This was done in mid-winter, with the thermometer well below zero. During the month of

of which they are made or increasing their size, renewals have been reduced to a great extent. Repairs are made in the field until the drill loses its efficiency. It is then taken to a well equipped machine shop, entirely dismantled and rebuilt. This allows all defective pieces to be noted and replaced properly.

Blasting

The friability of the ground is the chief factor of blasting. No set rules can be given for the most efficient use of explosives. The amount and kind of explosives to use must be determined by much experimenting. However, the following may be used as a basis upon which to start experiments. For holes 45 ft. in depth, use ten sticks of 60% semi-gelatine Red Cross powder to start chambering; the amount should be tripled for each succeeding chambering charge, that is, first 10 sticks, then 30 sticks, then 90 sticks, etc., until the chamber is large enough to receive the blasting charge. For a blasting charge use 25 lb. of black powder for every foot

of hole which has been drilled.

For holes 90 ft. in depth in solid hard rock, start chambering with 25 lb. 60% Red Cross powder, and triple each succeeding charge. Tamp the first charge with 20 gal. of water and triple the tamping with each succeeding charge. The blasting charge is 25 lb. black powder per foot of hole. A blast hole will break ground in back of it about one-quarter the distance it breaks in front. By the front is meant the side offering the least resistance. All blasting and chambering should be done by electricity, using electric exploders recommended by the powder manufacturers.

The following explosives are in use at Copper Flat: FF black powder for use in blast holes; stick Trojan No. 2 for use in blast holes in hard rock and for 'bulldozing'; bag Trojan for use in blast holes; 60% Red Cross powder for chambering; and 40% Hercules powder for chambering in soft ground.

During the year 1912 the following quantities and kinds of explosives were used:

	Lb. per ton.	Lb. per cu. yd. stripping.
Hercules 40%	0.0824	0.0910
Black FF	0.0762	0.2732
Stick Trojan	0.0689	0.1780
Bag Trojan	0.0439	0.1568
Gelatine 60%	0.0019	0.0037
Red Cross 40% N. G.	0.0059	0.0032
Red Cross 60% semi-gel.	0.0038	0.0031
Giant Ammonia 40%	0.0025	0.0015
Total	0.2855	0.7105
2.16 tons ore = 1 cu. yd.		

These quantities include explosives used in 'doby-ing' or 'bulldozing,' but in spite of that they show clearly the efficiency of the blast hole method.

China as a Tin Producer

China is one of the important tin-producing countries of the world, being surpassed only by the Straits Settlements and Bolivia. According to a recent consular report, the mine production is expected to reach 14,000 tons of tin for 1913. Nearly all the supply is brought from Yunnan to Hongkong, where it is refined and shipped to Europe and America or distributed to the Chinese market. The output of Yunnan is now hampered by limited water-supply, difficulty of transport, and the high cost of fuel and food. The Yunnan deposits have recently been described by one of the engineers engaged in the survey of a railway line from Nanking to Yunnan-fu, and it will be seen from the following statement that the Chinese production is likely to rapidly increase.

Ko-Chiu is situated in a depression on the summit of a range running northeast-southwest, latitude 23.18 N., longitude 103.10 E., is within about 21 miles of the treaty port of Meng-tze, and within 23 miles of the French railway station of Pi-Chi-Chai. Meng-tze, situated in the middle of a plain about 20 miles north and south by an average of 5 miles east and west, is a small town of 3000 inhabitants. Ko-chiu is at an elevation of 5916 ft., actual survey made by W. S. Dawley, on the survey

of the Pi-Chi-Chai Ko-Chiu railway, which it is proposed to build this fall. Meng-tze and the plain are at an elevation of 4725 ft. The plain and treaty port lie at the east of Ko-Chiu. There being no great supply of water at Meng-tze or on the plain, and no water at all at Ko-Chiu, the greatest part of the tin-bearing area cannot be worked, as water is essential to separate the ore from the sand. At present water even for drinking and domestic purposes has to be carried to Ko-Chiu from Meng-tze plain on mules. German interests have constructed a tin-refining plant at Ko-Chiu to turn out 50 tons of standard tin per day by coal-gas furnaces. It has never been fully worked, as all the coal has to be transported from Pi-Chi-Chai by mules, but as soon as the branch line is built, coal will be plentiful, and if water can be had the output will probably exceed 50 tons per day, as at present without a refinery the output is over 30 tons per day from the native smelters, which turn out tin averaging 84% pure, to be shipped to Hongkong for refining in native furnaces.

The Red river, which runs about 22 miles west of Ko-Chiu, is navigable by small boats up to a point nearly due west of Ko-Chiu (elevation 820 ft.), and a tributary rising to the west of Ko-Chiu falls nearly 4000 ft. in 22 miles. This is important, as at a point estimated about 18 miles southwest from Ko-Chiu about 10,000 hp. could be obtained. Ko-Chiu has a population of about 20,000 and is rapidly growing. Tin is found from the east side of the range, about 8 miles from Meng-tze, to the western bank of the Red river, an area 24 miles wide by about 56 miles long. It is required to deliver from the tributary of the Red river, before mentioned, to the town and mountain sides near Ko-Chiu and to the refinery, water to the extent of about 1,000,000 gal. per day of 24 hours, from a point about 18 miles distant and 3000 to 4000 ft. lower. The hydro-electric power would be generated (1) to supply the high-lift pumps with power, (2) to provide light for the towns of Ko-Chiu and Meng-tze, and (3) to supply power for mining purposes in Ko-Chiu and adjacent country. It is estimated that the total gross cost of such a scheme would equal about \$3,644,000, although this estimate might be considerably reduced, as a complete survey of the western slopes toward the Red river would in all probability result in a nearer source of supply being discovered.

Operations at the Braden mine, Chile, during August resulted in the treatment of 61,874 tons of ore, with 68.06% extraction, yielding 1,572,000 lb. of copper. Development advanced 31 metres in the Fortuna adit No. 2, in which the last 63 m. assayed 3.09% copper. No. 2½ Fortuna assayed in its last 9 m. 2.55% copper. Teniente No. 1 advanced during the month 61 m. In the latter opening an average assay of 4.39% was recorded in the last 72 m. July's assays in the same opening averaged 4.73% copper for a distance of 38 metres.

Mt. Morgan, Queensland, smelted 23,705 tons of ore in July, yielding 766 tons of blister copper containing 9384 oz. gold.

The Rand Banket and Its Gold Content—III

By C. B. Horwood

Structure of the Pyrite 'Pebbles'

The term 'concretions' denotes bodies of secondary origin, with superinduced structures of various sizes, usually spherical or lenticular; but, they may occur as layers, veins, crystals, or twin crystals, or as groups or aggregates of crystals. They originate by the aggregation of mineral matter around a central point, frequently about an original nucleus that may have been mineral matter, but more usually was organic. This growth is usually due to gradual accretion of mineral matter originally diffused through the rock; but sometimes the mineral substance has been introduced into the rock later by circulating solutions. Thus the growth has essentially been from within outward. Silicious, calcareous, or ferruginous concretions are the commonest. A concretion may be compact and homogeneous throughout or may consist of concentric shells. While compact externally, it may be much cracked and fissured internally. The cracks are widest toward the centre of the concretion and die out toward the circumference, as if the interior had contracted after the outside had dried and become consolidated. These cracks are often filled subsequently with mineral matter. That there is a great tendency for spherical concretions to assume either internal, radiating, or concentric structure is well known;⁸⁰ but, as far as the author is aware, no real attempt has been made to explain the reason of this. Apparently, the fact that such structures are exhibited by some of the pyrite 'pebbles' of the Rand conglomerate has been considered sufficient evidence for classing them as concretions. Later it will be shown that this may be a superinduced structure due to contraction; and if so, it does not necessarily imply a concretionary origin for the substance in which it occurs.

Crystalline and Concretionary Structures

In discussing, in 1907, the author's paper describing the Crown Reef occurrence, F. H. Hatch maintained that the 'pebbles' (specimens of which were exhibited at the meeting) were nodules with radiate structure, evidently of concretionary origin.⁸¹ Again, he and G. S. Corstorphine,⁸² referring to the presence of a considerable proportion of iron pyrite in the unoxidized portion of the Rand conglomerate, state that it occurs in grains that with the unaided eye can be seen to be sometimes round, sometimes partly

formed, and sometimes perfect crystals showing combinations of eube, octahedron, and pentagonal dodecahedron. Also, that larger rounded nodules of pyrite occur, some of which have quite a pebble-like appearance; and, further, they examined as many specimens of them as they had been able to obtain and in quite a number of them they had observed a radially fibrous structure, while others showed that the growth had been by concentric coats. They describe the appearance of specimens exhibiting radiate structure from the Buffelsdoorn mine,⁸³ and state that some from the same mine have a concentric structure. They point to the remarkable fact that almost every author who had previously referred to the rounded 'pebbles,' regarded them as owing their shape to attrition; but that, in their opinion, the bulk of the so-called 'rolled' pyrite owes its shape to growth by accretion.

Growth of Pebbles by Accretion

Merely to state an opinion that the 'pebbles' owe their shape to growth by accretion, or that they are concretions, proves nothing. It leaves the problem where it was before. Were they formed on, or only slightly embedded in, the soft ooze or matrix of a shingle deposit, in process of being laid down along some littoral, or in some estuary or delta? If so, they would have grown by accretion round some central point, making room for themselves by forcing aside the soft matrix; and would not have replaced quartz, as investigation with the aid of the microscope shows that they undoubtedly have done. Have they perhaps been formed in previously existing primitive cavities, spaces of discission or spaces of dissolution,⁸⁴ by precipitation from solution? It seems highly improbable that such cavities, if they ever existed, would have so effectively overcome the surrounding pressures as to have remained open sufficiently long to allow time for the formation of these 'pebbles.' Again, as already pointed out, it is hardly conceivable that they could be water-worn pebbles when one realizes the great age of the Witwatersrand conglomerates; the changes to which they have been subjected; how porous they must formerly have been, and how easily iron pyrite is decomposed and carried away in solution as iron sulphate by circulating solutions. Therefore, by what Posepny called negative indications⁸⁵ of metamorphosis, one

⁸⁰James Geikie, in his admirable work, 'Structural and Field Geology' (2nd Ed., 1908; Gurney & Jackson, London), devotes an interesting chapter to the discussion of 'Concretionary and Secretionary Structures,' from which the above description has been condensed.

⁸¹Abstract of the *Proc. of the Geol. Soc. Lond.*, No. 841, March 5, 1907.

⁸²'The Petrography of the Witwatersrand Conglomerates, with Special Reference to the Origin of the Gold,' by F. H. Hatch and G. S. Corstorphine, *Trans. Geol. Soc. So. Af.*, Vol. VII, Part III (1904); also, 'The Geology of South Africa,' by Hatch and Corstorphine (2nd Ed., 1909; Macmillan & Co.), pp. 142-144.

⁸³This is a banket mine, near Klerksdorp, about 100 miles southwest of the Rietfontein mines, and some 70 miles southwest of Randfontein.

⁸⁴See 'The Genesis of Ore Deposits,' by F. Posepny (2nd Ed., 1902), pp. 13 and 74 *et seq.* (published by Amer. Inst. Min. Eng.).

⁸⁵In treating of metamorphosis, he writes: "Frequently, however, there are only negative indications of the metamorphosis. It can be seen merely that the deposit is not an original rock, that it has not been deposited in pre-existing primitive or secondary cavities; and hence, that it must have been formed by replacement." F. Posepny, *loc. cit.*, p. 16.

is forced to the conclusion that, whether concretions or not, they must have originated by the replacement of some preëxisting matter.

Although in 1907, F. H. Hatch opposed the present author's conclusions that these 'pebbles' are metasomatic replacements of quartz and that possibly some are pseudomorphs after quartz pebbles, yet two years later he admits that the possibility of pseudomorphism after quartz must be considered.⁸⁶ Further, in support of this, he refers (as the present writer had done in 1907⁸⁷) to Kuntz's⁸⁸ description of the occurrence in the Meyer & Charlton mine, on the Central Rand, of conglomerate in which both quartz pebbles and matrix have been replaced by calcite.

Replacement of Quartz by Pyrite

The detailed study of the Crown Reef occurrence, already outlined, showed that the pyrite had replaced the quartz, either of the pebbles, or of the matrix, or of both as the case might be, the quartz going into solution while the pyrite was precipitated in its place. Further, it has been shown that the microscopical examination, in thin sections, of the Rietfontein Buckshot Reef demonstrated that in this case also, the pyrite pellets have been formed by the replacement sometimes of the quartzitic matrix and sometimes of the quartz pebbles of the conglomerate, the original structure and outlines of each being, in some of the pellets, still clearly discernible under the microscope. In others, which evidently represent a later stage, these outlines are obliterated and a radiate or concentric structure has been developed. Also, both the Rietfontein and Randfontein occurrences showed that in addition to the banket matrix being replaced, the angular slaty quartzite pebbles and the well rounded normal quartzite and quartz pebbles are pseudomorphically replaced by pyrite. Thus, in addition to merely negative indications, the detailed study of the actual occurrences combined with petrological investigation has now furnished direct evidence that these 'pebbles' are metasomatic products⁸⁹ that made room for themselves by the expulsion of an earlier material.⁹⁰ Close study underground; the examination under the microscope of thin sections of the 'pebbles'; similar study of transitional forms, such as those previously described, which fortunately have been preserved; and careful examination of hand specimens, have clearly shown that this is what has happened; and that as just stated, the pyrite sometimes replaced the quartzitic matrix, sometimes the quartzite or quartz pebbles, the former being apparently the more usual; and, further, that some 'pebbles' have been formed by the indiscriminate replacement of quartzite or quartz pebbles and matrix.

When the replacement took place it may, or it may not, have done so by equal volumes. From an examination of the plates accompanying this paper, it will be seen that around portions of the edges of the 'pebbles' there is frequently a growth of secondary crystalline fibrous silica.⁹¹ It is important to note that the direction of the position of the fibres is invariably at right angles to the edges of the 'pebbles.' This fibrous silica must obviously have been formed later than the 'pebbles.' Therefore, if replacement did not take place by equal volumes, then solution was more active than precipitation, the amount of matrix that was dissolved and went into solution having been greater than the amount of pyrite precipitated. If it were by equal volumes, some of the pyrite has since been dissolved; or after the deposition of the pyrite contraction of its mass has occurred. Thus, room was available in which this fibrous crystalline silica has been deposited. Probably the spaces now occupied by this silica never existed at any one time, in their entirety, as open cavities. If open spaces existed at all, they probably consisted of minute druses, or of pores in a porous mass. Precipitation of this silica probably took place either directly after or simultaneously with the precipitation of the pyrite; or (if the change was by equal volumes) simultaneously with its subsequent partial dissolution or contraction. The fibrous nature of the silica and the fact that the fibres invariably have a radial orientation round these pyrite bodies certainly suggest the influence, during its crystallization, of tensile stresses acting toward the centres of the pyrite bodies, such as might be due to the contraction of the pyrite.

Structure of Concretions

When discussing concretions, it was remarked that while perhaps externally compact, they may be much fissured and cracked internally; and, that these cracks are widest toward the centre, as if the interior had contracted after the outer portion had dried and hardened. These cracks are often wholly or partly filled with later mineral matter. Similar features are exhibited by many of the pyrite 'pebbles,' and analogy suggests the same explanation, indicating that the spaces now occupied by fibrous silica are due rather to contraction of the pyrite than to any balance between solution and precipitation having been primarily overcome by the former. The

⁸⁹Lindgren defines replacement or metasomatism as "the transformation of one mineral into another of different chemical composition, effected by practically simultaneous solution and precipitation." W. Lindgren, 'The Nature of Replacement,' *Econ. Geol.* Vol. VII, No. 6 (1912), p. 534.

⁹⁰See Posepny, *loc. cit.*, p. 17.

⁹¹Young has also noticed and called attention to the frequent occurrence (in association with pyrite 'pebbles') of this fibrous silica. R. B. Young, 'Notes on the Auriferous Conglomerates of the Witwatersrand,' *Trans. Geol. Soc. So. Af., Vol. X* (1907), pp. 18-23. In this connection it is interesting to note that, if the white powder found in the middle of many flints be examined under the microscope, in addition to minute organic skeletons composed of carbonate of lime, silicious sponge spicules will also be found. Some of the latter may be partly dissolved. In others, the original hydrated silica will be found to have been deprived of its water and converted into fibrous crystalline silica consisting of slender prisms crowded in radiate growth about centres. Presumably, this change has occurred by solution of the hydrated silica and its subsequent deposition in this form as secondary silica. However, it is possible that this secondary silica may be the result of a direct transformation of the hydrated silica or opal, but this is less likely. (See W. J. Sollas, *loc. cit.*, p. 149.)

small rounded or partly formed grains of iron pyrite, which occur in the matrix of the conglomerate, are too small for any appreciable contraction to have taken place. As regards the crystals of pyrite⁹² in the matrix, it is evident from their development⁹³ that the force of crystallization has come into play; contraction has not taken place, for the pyrite retains its sharp crystalline form, and therefore the definite arrangement of its molecules which determines that crystalline form has been retained, and the crystals are not partly or otherwise surrounded with secondary fibrous silica. The crystal faces of the pyrite cut across, project into, and are partly imbedded in the granules of the matrix, and sometimes also in the pebbles, without interstices or the slightest break in the contacts. The crystals fit closely into whatever the host material happens to be, in which they occupy exactly the spaces needed for themselves. Their metasomatic origin, unattended by contraction, is thus clearly demonstrated. The conclusion is therefore supported that, where space has been available around the 'pebbles', it has been due to the subsequent contraction of the latter, rather than to the pyrite having originally occupied less space than the material replaced. It is evident, at least in some instances, as will shortly be shown, that the pyrite does not now occupy so much space as the material dissolved; and there would seem to be sufficient reason for believing that contraction has taken place. This contraction may, or may not, have been sufficient to account for the whole of the space now occupied by secondary crystalline fibrous quartz. This is a matter to be discussed later.

Deposition of Metals

Sullivan⁹⁴ has pointed out that the immediate condition in which a metal is thrown down from solution by a silicate is of secondary importance, as the newly formed substance is subject to spontaneous change into a more stable form, as from an amorphous or colloidal to a crystalline structure;⁹⁵ and is also subject to the modifying and transforming influence of continually renewed portions of active solutions. He also proved, by numerous experiments undertaken in the chemical laboratories of the

United States Geological Survey, that the natural silicates precipitate the metals from solutions of salts, while at the same time the bases of the silicates are dissolved in quantities nearly equivalent to the precipitated metals, and that where exact equivalence is wanting it is attributable either to solubility of the mineral or to precipitation of basic salts.⁹⁶

Changes in Structure of Pebbles

As will be shown shortly, changes in structure have certainly occurred in the pyrite pebbles since the deposition of the pyrite. It is conceivable that the latter was first precipitated in an amorphous state and later assumed a crystalline form; perhaps existing first as marcasite,⁹⁷ and then, owing to molecular changes, as pyrite. The mere change from an amorphous to a crystalline mass would probably be attended rather by an increase than a diminution in volume, depending on the massing of the molecules in the crystals⁹⁸ and of the grouping of the crystals themselves. During precipitation some gaseous or liquid solutions and other impurities may have been enclosed, which later were either occluded or dissolved out, or both, causing contraction of the mass. That contraction has in some, if not in all, cases taken place is evident from the following considerations. In a few instances the struc-

⁹²The metals are precipitated as hydroxides, or basic salts, with metal silicate, and he points out that metallic sulphides could readily result from such basic compounds by reduction of the basic salts by a reducing agent. Aluminum and other silicates are present in the matrix of the banket, and an appreciable amount of that originally present may have been replaced by pyrite, which is present in the ore to the extent of about 2 to 3%. The petrological study of the banket shows that silicates, both those forming part of the groundmass or matrix and those present in the stony quartzite pebbles, as well as silica, have been replaced by pyrite. Sullivan's work indicates that in the case of solutions of salts of the metals the replacement of the silicates by sulphides has been accomplished in two stages. The same may perhaps apply in the case of the replacement of silica. A change from a sulphate representing the first stage, to a sulphide representing the second stage, might easily be accompanied by a reduction in volume. However, it is not really known in what form the metals were present in the solutions to which the mineralization of the banket is due; microscopical investigation of the banket certainly suggests that the replacement of silica and silicates by iron pyrite took place directly in one operation; in which case any reduction in volume would not be attributable to the double process, such, for example, as the precipitation of a sulphate and subsequent conversion to a sulphide.

⁹⁷The majority, if not all, of these 'pebbles' are composed of pyrite. Possibly a few consist of marcasite. Young states that at least some of them consist of marcasite, since specimens which have lain in the Johannesburg museum for more than ten years show a thick efflorescence of iron sulphate ('Further Notes on the Auriferous Conglomerates of the Witwatersrand,' by R. B. Young, *Trans. Geol. Soc. So. Af.*, Vol. XII (1909), p. 88.)

E. H. L. Schwarz pointed out to the present writer that an easy way to distinguish between the two is to rub the mineral with hydrochloric acid, when marcasite will show its tin-white color, while pyrite will remain yellow. Those 'pebbles' which the writer subjected to this test remained yellow.

⁹⁸The force of crystallization would here come into play. See 'Die geologische Bedeutung, des Wachstumsdruckes Kristallisierender Substanzen,' by K. André, *Geol. Rundschau*, Bd. 3, fasc. I (1912). Also, 'The Nature of Replacement,' by W. Lindgren, *loc. cit.* (1912), pp. 521-535.

⁹²Which are sometimes as much as $\frac{1}{4}$ in. or more in diameter.

⁹³Lindgren has pointed out that in metasomatic processes pyrite is one of the minerals which, contrary to the general rule, show such a strong tendency to crystallization that the crystal form asserts itself in rigid material. W. Lindgren, 'The Nature of Replacement,' *Econ. Geol.*, Vol. VII, No. 6 (1912), p. 533.

⁹⁴Sullivan, Eugene C., 'The Interaction between Minerals and Water Solutions,' U. S. Geol. Surv., Bull. No. 312, p. 61.

⁹⁵In this connection it may be recalled that metals are usually precipitated from solution in a fine state of division as amorphous powder. Copper, for example, is thrown down as a fine dark-brown amorphous powder in the cementation process for the extraction of copper from solution by means of scrap iron. Gold is precipitated on zinc in the extractor-boxes, in the cyanide process for the recovery of gold, as a fine black amorphous powder. When assaying gold, in the ordinary process of 'parting' (dissolving silver and any other impurities that may be present) with nitric acid, the gold comes down as a brown or almost black powder; possibly this is an unstable oxide, for on annealing it is quickly converted into crystalline gold of the ordinary color.

ture and outlines of the original quartzite or quartz pebbles or of the quartzitic matrix of the conglomerate have been retained in detail by the pyrite and are clearly discernible under the microscope, as though the interchange had been originally with either little or no change of volume. In others the original structure cannot be detected, and a radial structure is exhibited. The latter is due to radial cracks (like the cracks on the surface of mud after it has dried in the sun⁹⁹). When these cracks are sufficiently big, they become filled with secondary quartz, clearly demonstrating that this structure is not original but represents a later stage than that in which the structure of the replaced material is retained.¹⁰⁰ The total bounding space occupied by the pyrite, however, may be of the same size as before this alteration, as there is frequently no sign of any alteration having taken place in the original outlines or boundaries of the 'pebbles'; and the rock-mass itself has not been condensed into less space; indicating, in such cases, not a shrinkage of the pyrite from its boundaries, but that contraction has ensued¹⁰¹ within its mass. In the outcrops of Rietfontein 'buckshot' the pyrite of the pebbles weathers to a black oxide, which sometimes is all dissolved so that only the hollow spherical casts remain¹⁰²; the latter are divided into segments of spheres by radiating divisional walls formed of the secondary silica deposited in the radiating cracks, which were produced after the replacement of the original material by the pyrite and due to the subsequent contraction of the latter.

Concentric Structure

The concentric structure¹⁰³ can also be explained by contraction.

Davies¹⁰⁴ attributes the cracks occurring in septarian nodules and concretions to expansion caused by deposition of calcium carbonate in an argillaceous

⁹⁹Which result in a network of polygonal forms, exhibiting a tendency toward pentagonal and triangular shapes.

¹⁰⁰In this connection it will be interesting to recall James Gelkie's explanation of the highly puckered, crumpled, or contorted appearance sometimes exhibited by layers of chert in limestone. (Jas. Gelkie, *loc. cit.*, p. 121). He says: "The silicious solution may have been originally in a colloid or jelly-like condition, containing some percentage of water. Thus, when the material began to lose its water and solidify, the contraction of its bulk would give rise to much distortion and confusion—later accretions of silica filling up any fissures or cavities thus produced."

¹⁰¹Irving, J. D., 'Some features of Replacement of Ore-bodies,' *Jour. Can. Min. Inst.*, 14 (1911), pp. 395-471; *Econ. Geol.*, Vol. VI (1911), pp. 527-561, and 619-669; 'Types of Ore Deposits' (1911), pp. 220-298.

¹⁰²These are often more or less coated with carbon and sometimes contain a few small particles of gold.

¹⁰³It was evidently this structure that led Hatch and Corstorphine to assume that the growth of some of the pyrite pebbles had been by concentric coats. It is quite possible in some instances, where this structure is present, that the growth has taken place in this manner; but in most cases it is doubtless mainly due to contraction.

¹⁰⁴Davies, A. Morley, 'The Origin of Septarian Structure,' *Geol. Mag.*, March 1913. He points out that his theory, though arrived at independently, is not altogether new, as Seeley had previously come to the same conclusion (see Phillips's 'Manual of Geology,' edited by H. G. Seeley, Part I, p. 103). This article by Davies appeared after the first draft of this paper was written.

rock. He maintains that as each successive concentric shell became impregnated it would expand and tend to separate from the adjacent shell around which it was formed, exerting tensile stresses upon the latter, which would produce radial cracks growing wider toward the centre. He certainly shows how, under such particular conditions, expansion may occur. But, as regards the rest of his opinions, they do not seem to be supported by convincing arguments.

Radial and Spherical Cracks

Stresses exerted along radial directions would produce, not radial, but spherical cracks; radial cracks are produced by stresses along spherical directions. Also, if expansion had occurred, the radial cracks would grow wider toward the circumference, as is evident from the following: Consider, say, a section of a spherical concretion consisting of a series of spherical rings each of which is pulled outward by tensile stresses so that it takes up, say, the position previously occupied by the adjacent enveloping ring. This would happen if the material were plastic and elastic enough to expand circumferentially and occupy the larger circle. The resulting structure would be concentric, not radial. If, however, the material were not sufficiently elastic, then in order to lie along large circumferences, fracture of the rings would ensue, and only arcs of the smaller rings would lie along (and mark the positions of) the successively larger rings. As the tensile stresses would be more or less uniform, there should be no reason for more arcs in one case than in another, and the rings would split each into the same number of arcs, having the same orientation. Obviously, as the circumference of the concretion is approached the circles become larger and the cracks (that is, the gaps between the segments) also necessarily become wider. Thus, on the theory of expansion, generally speaking, spherical and radial cracks would occur together in the same concretion; and the cracks would be widest at the circumference. These two kinds of cracks, on the contrary, usually occur separately; and, the ordinary septarian cracks are widest toward the centre. This theory of expansion, then, does not explain the facts usually observed in concretions.

Formation of Pyrite Bodies

The pyritic bodies discussed in this paper have been formed not by impregnation, but by replacement of the host mineral; and so the argument of Davies in favor of expansion does not apply.

On mathematical grounds,¹⁰⁵ it can be shown that

¹⁰⁵For the considerations of the behavior on cooling of a heated spherical mass, I am indebted to a learned friend, a fellow of the Royal Society and a great mathematician and well known professor of applied mechanics and mathematics, who is so modest that he prefers that his name should not be mentioned.

While discussing contraction in a spherical mass, it is interesting and instructive to compare the conditions often obtaining around centres of igneous intrusions. W. H. Weed ('Ore Deposits near Igneous Contacts,' *Trans. Amer. Inst. Min. Eng.*, Vol. XXXIII, 1903, pp. 715 to 746) has pointed out that on igneous contacts vein-fissures occur, cutting both the igneous rocks and the contact rocks above them. These are caused by contraction due to crystalliza-

contraction in a spherical mass would produce either radiating cracks or concentric spherical ones, or both. Thus, if a section of a hot spherical mass be considered, it will certainly have some property that is much the same in all radial directions; but which is somewhat different in all circumferential or round

FIG. A.

FIG. B.

directions. See Fig. A. Call O P a radial, and Q P Q a round direction.

If there is much more contraction along the round than along the radial directions, actual fracture may result, producing radiating cracks and a series of pyramids with their vertices at the centre. This may often be seen in the round trunk of a tree that has been drying. As it contracts more in the round direction it cracks as shown in Fig. B, fracture ensuing along radial planes, because the tensile stresses are greatest on such planes. Since the mass becomes greater as the circumference is approached, so contraction will be greater and the cracks wider. A hot cylinder of mineral matter on cooling, supposing it to contract more in the round than in the radial direction, would have crystallization arranged along radial lines; and if it cracked, it would do so along radial lines as indicated in the figure; if actual cracking did not occur it would be in a state of internal strain along those lines. In a similar manner, if contraction occurs more in the radial than in the

round direction, every point equidistant from the centre would be in the same state of strain (and therefore also of crystallization); and if this were sufficient to produce fracture, a series of concentric rings would result.

In the case of the pyrite 'pebbles,' the angles, such as AOB and BOC in the accompanying figure, are approximately equal, which is what one would expect as a result of the contraction, on slow cooling, from without inward of a homogenous approximately spherical mass, for the stresses and strains would be distributed in a uniform manner and there should be therefore no reason for one angle to differ from another. When concentric structure is present, one would expect by analogy the rings to be about equidistant, which they are.¹⁰⁶ There is good reason to believe that these 'pebbles' were formed under high-temperature conditions;¹⁰⁷ there are many reasons for this

position, such, for example, as the presumably easy solubility of the silica at the time that it was replaced by pyrite, suggesting intense chemical activity of the solutions.

Radial Cracks

The cracks producing the radial structure in these 'pebbles' are widest at the circumference and have their vertices at the centre. It has already been shown that this would be so whether they had been produced by expansion or by contraction. The development of this structure results in a series of cones of pyrite having their vertices at the centre. Good examples of this can frequently be seen in pyritic nodules from the chalk beds of England. In these the writer has noticed that the bases of the cones tend to assume square or pentagonal forms;¹⁰⁸ and the spherical or otherwise rounded nodules frequently exhibit, instead of smooth contours, rough 'warty' ones, as a result of the tendency of the individual bases of the pyramidal cones to assume sep-

tion and cooling of the igneous rock and the shrinkage of the metamorphic zone above it. He points out that, as shown by Pirsson ('Complementary Rocks and Radial Dikes,' *Amer. Jour. Sci.*, Vol. 1, 1895, p. 116), the radial fissures, which form so remarkable a feature of certain igneous centres, are not due to the initial expanding force of the intruded magma, but to contraction-cracks. If the latter extend to a sufficient depth to reach still molten magma, they will be filled and dikes will be formed; if not, the cracks become channels for pneumatolytic vapors and later circulating waters, and true mineral veins may be formed. He points out that in addition to radial cracks, the shrinkage would also tend to produce cracks parallel to the borders of the intrusion (that is, concentric ones). In the Witwatersrand district the parallel cracks are marked by longitudinal, or strike, dikes, and the radial ones by transverse dikes. Here the former were intruded first and have been faulted by the latter.

In consideration of the later portion of this paper, his further remarks might conveniently be added here. He goes on to show that as circulating solutions traversing contact-zones would course through the more basic differentiated part of the magma, which is richer in metals than the normal magma, there would be a combination of conditions favoring ore formation; and so it is easy to understand why ore deposits occur in or near contacts of great igneous masses.

¹⁰⁶To study mathematically why these angles and distances are about the same is a difficult problem, and involves the consideration of the stresses in a spherical mass at high temperature cooling from the outside and yielding suddenly when the stresses reach a certain value.

¹⁰⁷Contraction need not, however, necessarily be due to cooling from a high temperature. Whatever its cause, if it takes place fairly uniformly throughout the mass, the results would be similar. It is only fair to state that in the case of either the flints or the pyrite nodules (which latter so often exhibit radiate structure) in the chalk beds of England, so far as the writer is aware, there is no direct evidence for assuming that they have been formed under high-temperature conditions.

C. Gilbert Cullis informed the writer that the oölite grains from the Bahamas show concentric structure; those from Salt Lake (Utah) show both concentric and radiating structure; at both these places oölite grains are being formed at the present time; while in practically all fossilized oölite grains both structures are seen. This is interesting, and it may be that in the first two cases the concentric structure is due either to contraction or to concentric growth, or to both; that in the second case radial structure is present only in the older grains; and that in the fossilized grains the radial structure has developed with time owing to slow contraction.

¹⁰⁸Which also suggests contraction. See a previous footnote about sun cracks.

arate projecting boundaries, made up of crystalline faces, rather than be merged in one continuous smooth circumferential surface; doubtless the soft yielding nature of the chalk, which in this case was the host mineral, was a favoring factor. These nodules and also the 'pebbles' of the Rand sometimes present a crumpled appearance, suggestive of subsequent contraction.

Radial Pebbles

In Fig. 11, the pyrite 'pebble' on the right exhibits radial structure, resulting in a circumferential series of radial cones having their vertices toward the centre. It will, however, at once be remarked that the central portion of this 'pebble' is a typical illustration of septarian structure with radiating cracks

FIG. 11. PYRITE 'PEBBLES' SHOWING RADIAL STRUCTURE, IN MAIN REEF LEADER.

dying out toward the circumference. It is fortunate that both structures are to be seen so well in this photograph, for here, probably, is indicated the clue to the whole problem. The outer series of cracks, which extend to the circumference and are responsible for the radiating cones of pyrite, obviously represent the main series of fractures. It has been shown that such cracks can be produced by either expansion or contraction. Which of these has operated in this case? The Davies theory of expansion pre-supposes impregnation of the host mineral by the secondary one, whereas these 'pebbles' have been formed not by impregnation but by replacement of the host mineral. Furthermore, the microscope reveals no indication of expansion, such as signs of pressure having been exerted by the replacement product against the enclosing rock. The conclusion is that these outer series of cracks have been caused by contraction. It is noticeable that they die out as the central portion¹⁰⁹ is approached. This indicates that the outer portion cooled, contracted, and shrunk on to this central portion. The latter was probably at a higher temperature than the former and still semi-plastic, which would result in little tongues of it (minute dikes and apophyses, so to speak) being forced up tiny fissures in the contracting crust similar to the way that the secular cooling of the earth's crust is supposed to result in crumpling and fracturing of the crust and consequent dike

intrusions. In this way, the reason the radiating cracks of the more central portion die out toward the circumference is simply explained. Irving¹¹⁰ has recently remarked that the observed facts show that in by far the greater number of metallic replacements there has been an appreciable decrease in volume, which finds expression in widely distributed cavities. In the pyrite 'pebbles' of the banket a decrease in volume is represented by porosity in the replacing material, as revealed in the form of later cracks either of definite form and orientation resulting in radiate or concentric structure, or quite irregular ones, such as those shown in Fig. 6 and 7, appearing in Part II of this series of articles. That this decrease in volume is due to subsequent contraction is evident (apart from considerations already discussed) from the fact that the boundaries of the 'pebbles,' in many cases, do not coincide completely with those of the original quartzite or quartz pebbles; or (in the case of replacement of the matrix, or matrix and pebble) of the pyrite 'pebble' as originally formed, the outlines of which are still clearly discernible (see Fig. 5, 9, 12B, and 14, printed in the *Mining and Scientific Press*, October 18). In such cases portions of the present boundaries fall within the original ones and the intervening spaces are filled with secondary fibrous silica. Had the pyrite, at the time of replacement, occupied less space than the material dissolved, the surrounding pressures would assuredly have closed any cavities due to differences in the spaces occupied before and after the change. Thus one is impelled to the conclusion that the change occurred by equal, or practically equal, volumes, and was frequently followed by contraction of the pyrite and deposition of secondary fibrous silica. Herein, apparently lies the explanation of the fibrous nature of the latter, with its fibres at right angles to the circumferences of the pyrite 'pebbles.' Pressure promotes solution,¹¹¹ therefore diminution of same retards solution and also causes a slackening of the speed of flow of the mineralizers, tending to cause precipitation. Thus it is easy to understand how subsequent contraction of the pyrite would cause diminution in pressure within the original boundaries, and consequently would retard solution and also tend to start precipitation of the silica simultaneously with the contraction of the pyrite. The contraction would set up tensile stresses, exerted in directions at right angles to the surface of the pyrite, resulting in the silica being drawn out into fibres during the process of its crystallization.

Although contraction has occurred, it does not therefore follow that the original volume of the pyrite was equivalent to the original volume of quartz (or quartz and silicates) dissolved. This may or may not have been the case in a metasomatic exchange.

(To be Continued)

Coal mine fatalities in the United States during June totaled 174, and for the first half of the current year a total of 1257, as against 1226 in the same period of 1912.

¹⁰⁹The darker portion in the plate.

Development of Converter Practice

By HERBERT HAAS

In the *Mining and Scientific Press* of November 2, 1912, there appeared an excerpt from the well known paper by John Hollway, 'A New Application of a Process of Rapid Oxidation by which Sulphides Are Utilized as Fuel,' presented before the Society of Arts (London), February 14, 1879. In the accompanying editorial, entitled 'Development of Converter Practice,' as is usual in articles dealing with the history of copper converting, Pierre Manhès receives sole credit for having developed the first successful copper converter notwithstanding the fact that Paul David, who was then Ingenieur-Directeur of the Védennes works (Vaucluse), of which Manhès was the owner and furnished the means for the trials, did a great deal of original work, and as metallurgical engineer and co-worker of Manhès should at least share equally with him in the honor of being the first to devise a successful copper converter. Nor can I agree with a possible inference from that editorial, namely, that John Hollway made his experiments to devise a process of bessemerizing copper matte. On reading his article critically it becomes apparent that what he advocated and was trying to do is pyrite smelting as practised today. Because he used the term 'bessemerizing' and gave to his experimental apparatus the name 'converter', a number of well known metallurgists ascribe to him the important initial work of bessemerizing. As a matter of fact, Hollway wanted to get away from the bessemer converter, and so states in his article, and describes a furnace as being more practical in carrying out his idea, namely, to produce matte from pyrite ore without the use of extraneous fuel.

Using Sulphides as Fuel

Robert Stiehl, in his chapter on pyrite smelting, in R. D. Peter's 'Modern Copper Smelting,' accurately remarks: "To John Hollway of England is due, therefore, the credit of being the founder of the smelting process advocated in these lines" 'A new application of Bessemer's process of rapid oxidation by which sulphides are utilized for fuel.' "When metals are extracted from their ores by fusion the necessary heat is always obtained by burning coal, coke, or other form of carbon. I wish, however, to remind you that sulphides can be made to burn in air, and are thus combustible substances, while oxides are bodies that have already burned, which as you know is the conventional expression for entering into combination with oxygen. The metallic sulphides, consequently, are natural combustible minerals, and my object is to prove that they can be utilized as a source of heat in certain metallurgical operations. The most important of the mineral sulphides is pyrite, both on account of its occurrence and the extent of its deposits." But Hermann A. Keller, in his chapter on 'Bessemerizing copper mattes', in the same work, as well as James Douglas,¹ again refers to Hollway as an

experimenter trying to apply the converter to the conversion of copper sulphides. Hollway had in mind the treatment of sulphide ores, and their conversion into a molten state with a corresponding concentration of the copper sulphide into a regulus, without the use of extraneous carbonaceous fuel, but did not attempt to convert matte into copper.

A few quotations from his article will bear me out in my views. "These experiments were carried out with the ordinary bessemer plant, but for many reasons a bessemer converter is not suitable for the reduction of *cold pyrite to matte*, nor has it any arrangement for allowing the *matte to accumulate out of the reach of the blast*." "The blowing being resumed, liquid sulphides accumulated on the tuyere hearth of the vessel, and *pyrite and sand were continuously introduced during the eight hours*."

Form of the Furnace

"It is probable that the form of furnace eventually adopted will be a *modification* of the ordinary blast-furnace, fitted with tuyere hearth * * *, the blowing would be continuous, the hot charge coming down to a fusion zone, the height of which over the tuyeres would be determined by the amount of air blown in, and the frequency with which the blown products are withdrawn, varying likewise with the composition of the charge. The products could be withdrawn by tapping, as with a *common blast-furnace, the matte being run off from a reservoir below the tuyeres, where it would collect. Being thus unacted upon and undisturbed by the blast, rich matte, or even metallic copper, could be produced.* By continuing the oxidation and producing Cu_2S , and *some metallic copper*, the gold and silver would be found with the metallic copper."

Application of the Welsh Process

In this last sentence Hollway discloses that he wanted to make use of the well known Welsh process of bottom smelting; the concentrating of silver, gold, and impurities in a small amount of metallic copper which, if separated from the white metal, would leave the latter remarkably free from impurities, thus facilitating and cheapening the refining process of the bulk of the copper. This well known property of certain metals and metalloids to form with copper saturation products, alloys, or 'solutions,' in preference to remaining in the 'white metal' was made use of later by David in his ingenious *sélecteur* or best selecting process of making copper bottoms in the converter, in lieu of the Welsh practice of doing it in the reverberatory furnace. He provided his converter with a pocket, in which was collected the copper reduced during the first 10 minutes of blowing on white metal. This copper acts as a collector or *sélecteur* for the impurities, like arsenic and antimony, tellurium and selenium, gold, and, to a lesser extent, silver. This small amount of copper (aggregating about 10% of the total amount converted per charge) is tapped and

¹Trans. Inst. Min. & Met., Vol. VIII, 1899.

leaves the rest of the copper reduced afterward (by continuing the blowing on white metal) remarkably pure and free from impurities. The importance of this practice for small works has been fully discussed by Paul David, Jannettaz, James Douglas, and others.

To continue Hollway's article: "If desired, the products could run directly into suitable reverberatory furnaces, when, after the *matte* had settled, the slag could be run off while yet in a molten state, and in which the *oxidation of the matte could be completed.*" Evidently it was Hollway's intention to oxidize this matte or white metal by the then used methods of reaction smelting, by roasting a portion of the matte and having the dead roasted and partly oxidized calcine (sulphates and oxides) react with the molten sulphides, as was done in the well known Nicholls process.

Hollway's Experiments

These quotations should prove conclusively that Hollway had not in mind the conversion of copper matte into blister copper, but that he wanted to smelt raw pyrite in order to get the copper in it into a more concentrated form, that of matte, which he wanted to collect in a hearth "*removed from the action of the blast.*" His experiments are indeed interesting as being the first authenticated attempt on record at pyrite smelting. His logic was sound as far as the well recognized facts were concerned, that sulphides can be made to burn in air and the metallic sulphides consequently are natural combustible minerals, but he made the mistake of trying to conduct the two distinct operations of smelting and of refining (which the bessemer process really is) at one and the same time and in the same apparatus. Starting with a pyrite ore, with 2 or 3% copper, and requiring the addition of $\frac{1}{2}$ to $\frac{3}{4}$ ton of silicious ore, the concentration of this small copper content in the original furnace feed into blister copper would have required the handling of 60 to 100 tons of material for every ton of copper. This presents many practical difficulties, unless the two operations of smelting and converting are conducted separately. He approached this problem more as a laboratory worker than as a man who has practical knowledge of furnace operations. A parallel approaching Hollway's work is found in the Knudsen process, which attempts to smelt and convert simultaneously. The Knudsen 'converter' is, however, lined with magnesite. This process was at one time in operation at Sulitjelma, Norway, and was also tried at the United Verde smelter, Jerome, Arizona.

The Copper Converter

Reviewing briefly the essential features of the development of the copper converter, it will be found that the idea of applying the converter to the conversion of copper matte occurred to several soon after Sir Henry Bessemer's address at the Cheltenham meeting before the British Association on August 11, 1856, "on the manufacture of malleable iron and steel without fuel." Gossage, Baggs, and Keates secured patents to apply the process to copper matte in 1856. Four years later, Hunter secured

a similar patent. In 1862 the Glass and Lecere patents followed.² In 1866 Peter von Rittinger, better known through his extensive work on ore dressing, advocated the adoption of the Bessemer process to copper sulphides, and made experiments in Hungary, in 1867, at the Schmollnitz works. In *Oesterreiche Zeitschrift für Berg-und Hüttenwesen*, 1886, pages 68-71, there is a description of his attempt to convert matte in the reverberatory furnace by passing a pipe through the matte and blowing air through the molten bath. This 'Zugutebringen der Kupferrohleche durch Verblasen derselben nach Bessemer Art' (Beneficiation of copper mattes by blowing according to Bessemer's process) met, however, with no more success than the previous attempts of others.

Bessemer Converter in the Urals

More successful was the work done at the Wotkinsk smelter in the Urals, in 1866, after Sememikow, a mining engineer, and director of the Bogoslovsk mining district, had proposed the application of the bessemer converter to the blowing of copper matte to black copper. The blowing was, however, only carried to the white metal stage, with 72 to 80% copper. The matte converted contained 31.5% Cu, 25.3% S, 39.4% Fe, and the concentrated product had the composition 77.5% Cu, 19.3% S, 1.76% Fe. The slag assayed 34.46% SiO₂, 4.73% Al₂O₃, 3.06% CaO, 55.26% FeO, 2.13% CuO, 0.11% S, and metallic copper 1.7%. About 1300 lb. was handled per charge. An English type of then standard steel converter was used. This blowing operation, taking about 20 minutes time, obviated at least one roasting and re-smelting of the matte by a slow and tedious process, the white metal thus obtained by converting being dead roasted and smelted to black copper in a reverberatory furnace.³ The patents of Rath in America in 1866, of Dixon in England in 1869, of Gibb, Gelsthorp, and Tessie du Motay in 1870, and of Lavoissier in 1874 evince the interest men gave to this matter of devising a successful process for the bessemerizing of matte.⁴ In 1878 and 1879 Hollway made his interesting experiments in pyrite smelting.

The Védennes Smelter

In 1880 Pierre Manhès and Paul David attacked the problem at the Védennes smelter, in Vaucluse, France, of which Pierre Manhès was the owner, and David the engineer in charge. Fortunately, they did not know of the many failures that had preceded their work, or it might have discouraged their efforts. They made their first experiments in a small steel converter, holding a charge of about 110 lb. It had a wind-box in the bottom, and the tuyeres were vertical, thus admitting the blast into the molten metal from the bottom. They began with a matte containing 25 to 30% copper, which was first melted in a reverberatory furnace. The lining was made of sand. The operation went along

²Bulletin de la Société Scient. Industrielle de Marseilles, 1901, pp. 78-79.

³Berg-und Hüttenmannische Zeitung, 1871, p. 7 et seq.

⁴P. David, Bulletin de la Société Scient. industrielle de Marseilles, 1901, p. 78.

nicely until the matte had been concentrated into white metal. Then, after the tuyeres had been cleared, there was a violent boiling and foaming of the charge, and a portion of the charge was thrown out. It is quite possible that the slag had not been removed and that when blowing on white metal began, the well known phenomenon of 'foaming' was the result. This takes place when the white metal is blown with the slag still covering it. As the oxidation of the white metal proceeded, and the copper was thrown down, being immediately above the tuyere orifices, and having no heat producing impurities to give off, it chilled. The tuyeres clogged, and the blow came to a premature end. Variations of the copper and iron content of the matte had no appreciable influence on the result.

Difficulties with the Early Converters

But Manhès and David were not discouraged by these first failures. They soon discovered that the chief difficulty appeared to be the clogging of the tuyeres by the chilling of copper, which cut off from the superimposed white metal the wind supply and thus stopped the blowing operation. They exchanged the vertical tuyeres for horizontal ones, placed a few inches above the bottom of the converter. The wind-box was changed into a hollow ring which supplied the blast to the different tuyeres. This arrangement is similar to the one used later on blast-furnaces instead of the bustle pipe and tuyere pipes, the main delivering the air into this wind-box, this type of furnace having been used at Bisbee at one time (1902-1903). With this construction they overcame the difficulties first encountered, the copper remained liquid until the entire charge was blown, even in this small apparatus.

In view of Holloway's work and that of Manhès and David, it is significant that the latter two started with matte, recognizing from the start the essential differences between a bessemerizing operation and a purely smelting operation, starting with raw ores. Another departure they made from steel bessemerizing is that they initially intended to have the sand lining furnish the silica required for slagging the iron, whereas Holloway painstakingly tried to avoid the attack on the gannister lining of the converter by attempting an impossible silicious slag. Since the extent to which iron and silica combine with each other in the acid copper converter is left to the free disposition of these two substances, the natural slag is a basic one, and for this reason a basic lining is the successful lining of the copper converter of today.

The Eguilles Plant

After these preliminary trials, conducted over a period of one year at Védennes, the process was introduced on a larger scale at Eguilles, near Sorgues, Vaucluse. The new works consisted of three blast-furnaces, two reverberatories, and three converters. In 1884 the plant was increased to five blast-furnaces, two reverberatories, six converters, and two refining furnaces.⁵ As a variety of mattes had to be treated (mattes high as well as low in iron and

correspondingly low and high in copper), with the variety in custom ores handled and treated, it frequently happened when blowing low-grade matte that the enriched matte or white metal would be *below* the tuyeres, so that the blowing was on slag, and the charge could not be blown to a finish, yielding copper. This difficulty was first overcome by removing the enriched matte or the white metal to another converter and finishing the blow in that manner. But it soon led to the adoption by Paul David, in 1885, of a cylindrical form of converter that could be turned around its central longitudinal axis. With this construction the relative position of the tuyeres could be changed (raised or lowered), so that a variety of mattes could be blown in the same converter and in one operation. It also reduced the blast pressure needed. It is this cylindrical form of converter that was introduced at Livorno, Italy (known as the Leghorn converter), and adopted later by the Copper Queen Con. Mining Co. for its Bisbee works.

Soon after success had been achieved by Manhès and David at Védennes, the Société de Metallurgie du Cuivre (procédé Pierre Manhès) was formed to exploit the process. Vernis, who had formerly worked at the Eguilles works, built and operated for one year the first converters in America, those of the Parrot Silver & Copper Co., at Butte, Montana. Franklin Farrel, of course, was instrumental in introducing the process in the United States, and deserved the credit of 'pioneering.' This is all the more creditable, because the Anaconda was then, as it is now, the largest copper producer in Montana, its production then being nearly 50% of the total state production, whereas that of the Parrot works was materially less. The Parrot works was the only works which at that time shipped black copper, or blister copper, the other works shipping rich matte.

Ore Reserves of Australian Mines

The following data were recently compiled by the *Kalgoorlie Miner*, and cover the larger properties in ten districts:

Name.	Short tons.	Value per ton.
Great Boulder	731,260	\$13.28
Golden Horse-Shoe	799,800	7.28
Ivanhoe	1,080,850	9.74
Kalgurll	250,000	9.60
South Kalgurll	252,480	5.70
Lake View & Star	423,720	6.82
Perseverance	856,740	5.58
Oroya Links	126,740	6.08
Chaffers	104,000	6.90
Sons of Gwalla	560,000	7.68
Bullfinch Prop.	158,300	12.42
Inglston Consols	60,000	11.76
Queen of the Hills	86,000	10.92
Fenlan	70,000	19.20
Corinthian North	158,600	5.92
Edna May	20,000	20.40
Sand Queen	30,000	19.20
Royal Standard	56,000	8.76
Black Range	15,000	10.80
Mountain Queen	23,780	6.96
Burbank's Main Lode	34,000	9.60
Marvel Loch	13,000	6.24
Ida H.	15,000	15.30
Great Fingall	21,150	6.34

The New Tariff on Mineral Products

A comparison of the duties under the old tariff and the present Underwood-Simmons law which recently was put into effect by President Wilson, is shown in the following table:

Schedule A—Chemicals, Etc.

	Old tariff.	New tariff.
Acid, sulphuric, or oil of vitriol, ns. pf.....	¼c lb	free
Alumina, hydrate of, or refined bauxite:		
not over 64% alumina.....	4-10c lb	15%
over 64% alumina.....	6-10c lb	15%
Alum, alum cake, patent alum, sulphate of alumina, aluminous cake, containing not over 15% alumina and over 0.3% iron oxide....	¼c lb	15%
containing over 15% alumina or not over 0.3 iron oxide.	¾c lb	15%
Alumina, manufactured compounds of, not specially provided for	25%	15%
Ammonia, carbonate of.....	1 ½c lb	¾c lb
muriate, or sal ammoniac...	¾c lb	¾c lb
phosphate of		1c lb
liquid anhydrous	2 ½c lb	5c lb
Ammoniacal gas liquor.....	20%	10%
Barium, chloride of	25%	¼c lb
dioxide of	25%	1 ½c lb
carbonate of, precipitated..	25%	15%
Cobalt, oxide of	15%	15%
Baryta, sulphate of, or barytes, including barytes earth:		
unmanufactured, per ton...	\$1.50	15%
manufactured, per ton.....	\$5.25	20%
Lead pigments:		
Litharge	2 ½c lb	25%
Orange mineral	3 ¾c lb	25%
Red lead	2 ½c lb	25%
White lead	2 ½c lb	25%
All pigments containing lead dry or in pulp, and ground or mixed with oil or water not specially provided for.	2 ½c lb	25%
Lead, acetate of, white.....	3c lb	1 ¼c lb
nitrate of	2 ¼c lb	1 ¼c lb
acetate of, brown, gray, or yellow	2c lb	1c lb
all other compounds of, not specially provided for....	25%	20%
Potash: Bicarbonate of, refined	25%	½c lb
chlorate of	2c lb	½c lb
chromate of	2 ¼c lb	1c lb
bichromate of	2 ¼c lb	1c lb
cyanide of	12 ½c	free
nitrate of, or saltpeter, refined	½c lb	\$7.00 ton
permanganate of	25%	1c lb
prussiate of, red.....	8c lb	2c lb
yellow	4c lb	1 ¼c lb
Salts and all other compounds and mixtures of which bismuth, gold, platinum, rhodium, silver, or tin constitute the element of chief value	25%	10%
of uranium	free	10%
Soda: Benzoate of.....	20%	5%
chlorate of	1 ½c lb	½c lb
nitrate of	2c lb	½c lb
bicarbonate of, or supercarbonate of, or saleratus...	¾c lb	¼c lb
other alkalies containing 50% or more of bicarbonate of.	¾c lb	¼c lb
hydrate of, or caustic.....	½c lb	¼c lb
phosphate of	25%	¾c lb
hyposulphite of	¾c lb	¼c lb
sulphide of, containing not over 35% sulphide of soda containing over 35% sulphide of soda.....	¾c lb	¼c lb

	Old tariff.	New tariff.
sulphite of	25%	¼c lb
chromate and bichromate of	1 ¾c lb	¾c lb
yellow prussiate of.....	2c lb	¾c lb
borate of, or borax refined.	2c lb	¼c lb
crystal carbonate of, monohydrate, and sesquicarbonate of	¼c lb	¼c lb
sal soda	1/6c lb	¼c lb
crystals, not concentrated..	1/6c lb	¼c lb
concentrated	¼c lb	¼c lb
cyanide of	25%	free
sulphate of, crystallized, or Glauber salts	\$1.00 ton	\$1.00 ton
Zinc, oxide of	1c lb	10%
white sulphide of	1 ¼c lb	15%
lithophone	1 ¼c lb	15%
pigments containing, but not containing more than 5% lead, ground dry.....	1c lb	10%
when ground or mixed with oil or water.....	1 ¾c lb	10%
chloride of and sulphate of	1c lb	½c lb

Schedule B—Earths, Etc.

Firebrick, not over 10 lb each; not glazed, enameled, painted, vitrified, ornamented or decorated in any manner...	\$1.25 ton	10%
glazed, enameled, etc., as above	35%	15%
more than 10 lb each; not glazed, enameled, etc., as above	30%	10%
glazed, enameled, etc., as above	35%	15%
Brick, magnesite, chrome, and brick not specially provided for; not glazed, enameled, etc., as above.....	25%	10%
glazed, enameled, etc., as above	35%	15%
Roman, portland, and other hydraulic cement, in packages	8c 100 lb	free
in bulk	7c 100 lb	free
Cements, all other, not specially provided for.....	20%	10%
Lime	5c 100 lb	5%
Plaster rock or gypsum, crude ground or calcined.....	30c ton	10%
	\$1.75 ton	10%
Clays or earths, unwrought or unmanufactured, not specially provided for.....	\$1.00 ton	50c ton
wrought or manufactured, not specially provided for	\$2.00 ton	\$1.00 ton
China clay or kaolin.....	\$2.50 ton	\$1.25 ton
Fuller's earth, unwrought and unmanufactured	\$1.50 ton	75c ton
wrought or manufactured..	\$3.00 ton	\$1.50 ton
Fluorspar	\$3.00 ton	\$1.50 ton
Asphaltum and bitumen, crude, if not dried or advanced in any manner.....	\$1.50 ton	50c ton
if dried or otherwise advanced in any manner...	\$3.00 ton	50c ton
The weight of the casks or other containers shall be included in the dutiable weight.		
Mica, unmanufactured, valued not above 15c lb.....	5c lb & 20%	4c lb
valued above 15c lb.....	5c lb & 20%	25%
cut or mica splittings, built up mica	10c lb & 20%	30%
manufactures of, wholly or in chief value	10c lb & 20%	30%
ground	20%	15%
Marble, breccia, and onyx, sawed or dressed, over 2 in. thick	\$1.00 cu. ft.	75c cu. ft.

	Old tariff.	New tariff.		Old tariff.	New tariff.
Marble or onyx slabs or paving tiles, not less 4 superficial inches, not over 1 in. thick	8c sup. ft.	6c sup. ft.	hammered iron not specially provided for.....	6-10c lb	5%
over 1 and not over 1½ in. thick	10c sup. ft.	8c sup. ft.	beams, girders, joists, angles, channels, T's, columns and posts or parts or sections of columns and posts, deck and bulb beams, and building forms, together with all structural shapes of iron or steel—not assembled or manufactured, advanced beyond hammering, rolling or casting, value 9-10c lb or less.....	3-10c lb	10%
over 1½ and not over 2 in. thick	12½c sup. ft.	10c sup. ft.	valued over 9-10c lb.....	4-10c lb	10%
If rubbed in whole or in part, in addition	2c sup. ft.	2c sup. ft.	punched or fitted for use, or whether assembled or manufactured	45%	10%
Marble or onyx mosaic cubes, not over 2 cu. in., if loose. ¼c lb & 20%	¼c lb & 20%	20%	sashes, frames	45%	10%
If attached to paper or other material	5c sup. ft. & 35%	35%			
Marble, breccia, onyx, alabaster and jet, wholly or partly manufactured into monuments, benches, vases, and other articles, or of which these substances or either of them is the component material of chief value	50%	45%	Iron or steel, boiler or other plate, not thinner than No. 10 W G, cut or sheared to shape or otherwise, or unsheared—value 8-10c less per lb.....	3-10c lb	12%

BUTTE, MONTANA

WASHOE SMELTER RESUMES WORK.—EAST BUTTE MINE.—
BUTTE & SUPERIOR ZINC.—ELECTRIC RAILWAY COMPLETE.
—CORBIN COPPER CO.—EXTRALATERAL RIGHTS.—BARNES-
KING AND BUTTE & BALLAKLAVA.—U. S. ASSAY OFFICE.—
LEACHING PLANTS.

The Anaconda smelter is at work again after the 10 days' shut-down required to clean and repair the flues leading to the big stack. The flues had been used continuously for ten years without inspection, and hereafter it is proposed to clean and repair them every five years. The amount of dust taken from the flues and its value make large figures, namely, 12,000 tons of dust, valued at \$300,000. When removed from the flue, the dust had to be wet down to keep it from blowing away. It will be briquetted for re-treatment.

Now that the East Butte Copper Co. is engaged in increasing its smelter capacity from 1,250,000 to 2,000,000 lb. per month, it behooves the management to be sure of sufficient ore reserves in the mines to keep the smelter busy. To this end the main shaft is being deepened to the 1800-ft. level, or 600 ft. lower than the present stopes. Also, the Dutton shaft, which the old Pittsmtont management never sank below the 600-ft. level, is to be unwatered and deepened, on the assumption that sufficient exploratory work had not been done previously to justify the abandonment of the shaft. On the whole, the future of East Butte seems brighter than at any time in the past, and its efficient management is to be complimented for having so ably resuscitated a doubtful-looking venture.

At the present rate of production of zinc concentrate, nearly 6000 tons of concentrate per month, the Butte & Superior is probably the largest zinc mine in the world.

The electrification of the Butte, Anaconda & Pacific railway has been completed, and it will not be long now before electric will be substituted for the present steam locomotives. The trial run of a train recently between Anaconda and Butte, was witnessed with keen interest by officials of the local railway and also by A. J. Earling, president of the Chicago, Milwaukee & St. Paul Railway system. Mr. Earling was particularly pleased with the success of the test, in view of the fact that his Company is contemplating the electrification of a long stretch of its main tracks through Montana.

Reports from the East state that the Corbin Copper Co. has raised sufficient funds to enable it to sink the Gambrinus shaft in Butte and properly to explore the ground. It is not made clear whether the funds are also sufficient to complete the purchase of the property in case the development should justify that step.

The deep orebodies of Butte are a continual source of anxiety to their owners. Shafts are sunk to great depths before cross-cutting to the veins, and it often proves difficult to say with certainty to which outcropping vein the discovered orebody belongs. Now comes new proof of this in a suit just brought by the Anaconda Copper Mining Co. to enjoin the Pilot-Butte Mining Co. from working a certain orebody on the 2000-ft. level of that mine. The Anaconda company asks that the Pilot-Butte company be restrained from working on the disputed orebody until sufficient development work has been done by both parties concerned to satisfy them of the real conditions. The Pilot-Butte company admits that the vein in question has its apex in Anaconda ground, but believes that it junctions with the Pilot vein 1600 ft. below the surface, from which point down it should belong to the Pilot-Butte because of the older location of the Pilot vein.

The Barnes-King Development Co. continues to prosper. Since December of last year the Company has mined 37,000 tons of ore from the North Moccasin property with net bullion returns of \$302,000, or \$8.23 per ton. Mining and milling expenses absorbed \$128,000, the former North Moccasin owners were paid \$130,000, and \$43,000 was retained by the Barnes-King company.

As the rumor still persists in Boston that the Anaconda

Copper Mining Co. is negotiating for the purchase of the Butte & Ballaklava Mining Co., it can be once more authoritatively stated from Butte that the story has positively no foundation in fact.

In spite of the vigorous efforts of local congressmen to stave off the sentence, the United States Assay Office at Helena seems doomed to disappear. Congress has not made the necessary appropriation for its further operation, and lamentations fill the air locally. The United States Assay Office has been an institution of historic interest in the community, even if Congress can find no justification for its continuance.

Increased activity and production characterize the experiments with copper leaching on the east side. The Butte-Duluth company reports 2850 tons mined and milled during September. This ore yielded 27 lb. of copper per ton at a reported total cost of \$2.64 per ton, or 9c. per pound of produced copper. If these costs allow for proper amortization on equipment, the showing is certainly creditable and argues well for the success of the process and of the mine. The Company is mining its ore by open-cut methods, drilling holes for blasting by churn-drills as in the porphyry coppers. Churn-drilling is also under way in blocking out and proving the orebodies.

RHODESIA

THE GIANT PROPERTY.—PROSPECTING IN THE TERRITORY.—
NATIVE LABOR SITUATION.

The Giant Mines of Rhodesia, Ltd., has been a particularly unfortunate property lately. A few years ago the mine was one of the leading profit earners of Southern Rhodesia, but today, although it continues to yield fairly satisfactory returns, it is clear that the property is falling from its hitherto high estate and the future seems full of uncertainty. A year or two ago it was announced that, on account of faulting, the vein had been lost on the lower levels. Despite extensive and costly boring operations and the employment of an eminent geologist in the person of G. S. Corstorphine, of Johannesburg, the Company so far appears to have met with little success in the re-discovery of the lode, a banded ironstone body associated with chloritic and talcose schists. The troubles of this Company have lately been further increased by subsidence of ground. During July the tonnage treated was substantially reduced, and there was a consequent decline in profit, due to trouble with ore passes during the

HUNTINGTON MILL PLANT, CAM MINE, MASHONALAND.

month, this being the outcome of caving-in of certain stopes. One who knows the underground workings of the Giant can scarcely be surprised to learn that some of the levels are occasioning the management considerable anxiety, and large quantities of the hanging wall have fallen in. The vein is lenticular in character, in some places narrowing down to a few feet, and in others attaining widths of over 100 ft. In the past the management stoped the mine with little regard to pillars or means of supporting the roof, and the Company now has to pay the penalty for the faulty methods pursued then. It was anticipated that the returns for August and the current month would be substantially better than those obtained in July. Notwithstanding, it cannot be denied that the mine is in

anything but a satisfactory state at present, and whether the lost vein is found or not, the management will have an anxious time. While on this point of insecurity of workings, it may be remarked that the Giant is far from being the only mine in Rhodesia which is open to criticism in this respect.

The dry season in Rhodesia, which extends throughout the so-called 'winter' months, from April until the end of October, is the best and most favorable time of the year for the carrying on of prospecting operations. In the first place, a prospector can count on the absence of rain for at least five months, and he is not subject to the tropical deluges of the summer; transport is easier, and the climate more pleasant. In the second place, about June the tall rank grass becomes dry, bush fires spread all over the country, and rocks which are obliterated after the rains can be examined *in situ*. During this dry season there has been the usual exodus of prospectors from Salisbury, Bulawayo, and the other mining townships, to the *veldt*, and a considerable number of discoveries have been reported. What their value is can only be determined after further development and preliminary crushing. While there have been large numbers of men investigating promising localities in both the Matabeleland and Mashonaland provinces during the past few months, it is doubtful whether there has been as much prospecting activity this dry season as in former years. The country is just beginning to recover from a period of severe depression which was accentuated by the severe drought of last summer; consequently there has not been nearly so much money for the exploration of outlying areas as in more prosperous times, and it is noticeable that, while new properties are being staked, groups of claims continue to be abandoned and forfeited to the Government in numerous localities. In the Gwelo district alone, about 100 claims were forfeited a week ago, and upon instructions from the Secretary for Mines, are now open and may be re-located.

At the quarterly meeting of the Rhodesian Chamber of Mines, held in Bulawayo at the beginning of September, P. B. S. Wrey, who presided, mentioned the signing of an agreement between the Portuguese Government and the local authorities providing for the recruiting of natives by the labor bureau in the Tete district of Portuguese East Africa. In the past, the Witwatersrand Native Labor Association has drawn extensively from this area, but on account of adverse health conditions, the Union of South Africa Government recently took steps to reduce the importation to the Rand of tropical natives, these including natives from the Tete district. The granting of recruiting facilities to the Rhodesian native labor authorities in this densely populated district is of great importance, and is partly due, no doubt, to the satisfactory mortality statistics referred to by the chairman at the meeting. Thus what is the Union of South Africa's loss is Rhodesia's gain. Referring further to the native labor position, Mr. Wrey stated that the average number of natives employed in Rhodesian mines for the first six months of the current year was 31,909, which is 3500 less than the average number employed during the same period in 1912. Toward the end of the current year, however, the demand is likely to be keener, as a larger number of local natives than usual may be expected to return to their homes for the plowing season, while several large new plants will be working and need help. Taken on the whole, the native labor outlook is decidedly hopeful at the time of writing. 'Boys' are coming in freely, and although mines like the Shamva and the Cam & Motor will soon call for a substantial augmentation of the complement at present available, there is little doubt that a sufficient number will be forthcoming when called for. At the same time, there is scarcely likely to be a large surplus, and accordingly the granting of facilities for recruiting in the Tete district will be greatly welcomed by both the mining and agricultural industries.

During the first six months of the current year the mineral output of Southern Rhodesia shows an advance in value of £85,894 in comparison with the corresponding six months of last year. In gold the increase amounts

to 21,439 oz. and £89,655 in value. The increase in coal sales was 2900 tons; in scheelite and wolfram, 327 tons; and in the value of diamonds declared, £5877. In respect of silver, lead, and chrome iron ore, there were decreases of £1770, £1582, and £9513, respectively. The total production for the six months of the year was valued at £1,521,387, while the output of gold for July constituted a record. It is probable that this rate of output will be maintained until the close of the year, when an increase in production is practically certain. In any case, the mineral output for 1913 should constitute a material increase over that of 1912.

DEADWOOD, SOUTH DAKOTA

BLACK HILLS BULLION PRODUCTION.—OPERATIONS AT THE DAKOTA, BISMARCK CONSOLIDATED, RATTLESNAKE, HILL CITY, AND BLACK HILLS TUNGSTEN MINES.

That the mining industry of the Black Hills is in a flourishing condition is reflected in the receipts of the United States Assay Office at Deadwood during the last quarter ended September 30. According to L. P. Jenkins, the assayer in charge, the purchases of bullion amounted to \$2,018,500, all of which came from Black Hills mines. During the history of the office there was but one quarter's business in excess of this amount. This does not represent the entire production of the Black Hills for the period, as the output of smelting ores, which are shipped to Omaha and Denver, are not included. At the present rate of production the year 1913 should exceed 1912, which was the banner year for the district, according to the U. S. Geological Survey figures.

Announcement is made by the Forest Service that a number of tracts of land within the reserve will be opened for homesteading. The land in question is in the limestone range, and is particularly adapted to the raising of small grain, hay, and potatoes, and includes considerable good grazing land. The tracts are within easy reach of the mining towns of the Black Hills, and were they cultivated might reduce the high cost of living among the miners. P. H. Bertschy has resumed work on his leases on the Dakota ground, at Trojan, and is shipping his output to the New Reliance mill. Formerly he shipped to the L., D. & W. mill at Terry, but when that plant suspended operations in August he stopped work.

An assessment of one cent per share has been levied by the Bismarck Con. Mines Co., operating a property adjoining the Wasp No. 2, at Flatiron. It is expected that this assessment will take care of all current liabilities and provide a working fund which will enable the property to be put on a good footing. Since starting last spring the mill has attained its normal tonnage of 250 tons per day, with practically no repair expense, and mining operations have been accomplished at a minimum cost. Everything would seem to point to an ultimate success, and the future of the property is promising.

At the Rattlesnake mine, in the Galena district, good progress is being made in the erection of the 20-stamp mill and cyanide plant. The machinery equipment was purchased from the North Star mine, at Custer, and is in excellent condition, having had but little use. The cyanide department is all new, and the whole plant will be operated by electricity. C. B. Harris, of Galena, is manager of the property.

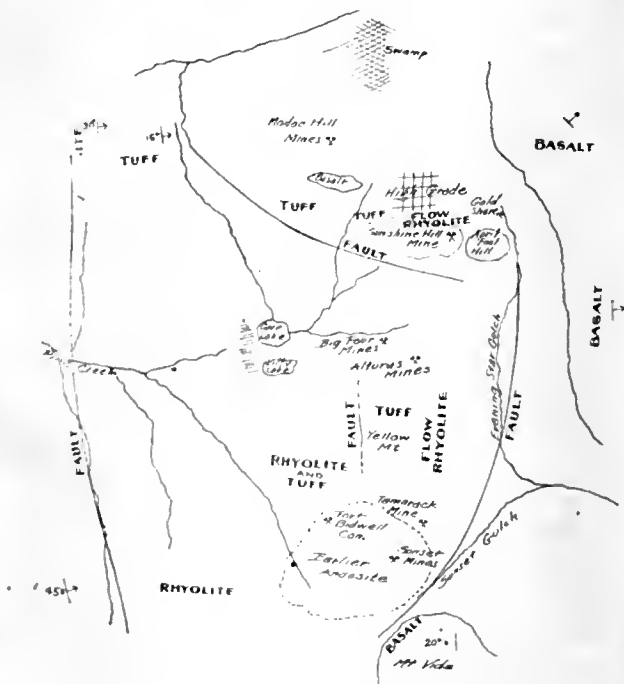

A double-drum hoist, 4-drill air-compressor, drills, steel, cages, pumps, boilers, etc., in fact a complete mining output, has been purchased by the Hill City M. & D. Co., and will be immediately removed to the property and erected at the main shaft, which is now 100 ft. deep. The shaft will be sunk to 300 ft. and a level opened at the bottom and at the 150-ft. point. H. B. Lake, of Hill City, is president. Denver people are interested in the Black Hills Tungsten Co. and are making an earnest endeavor to put the mining of wolframite on a commercial basis, having just completed a small concentrating plant near Hill City. The plant is being tested, and results will be awaited with much interest. The district in which the plant is situated is known to contain a large amount of low-grade wolframite ore.

HIGH GRADE, CALIFORNIA

PRESENT CONDITIONS IN A PROMISING DISTRICT.—WORK GOES ON STEADILY AT A NUMBER OF PROPERTIES.—GOOD ORE AND GOOD CONDITIONS.

Within the last two years since the ill-advised boom the men who have stood by the district have made substantial strides toward the placing of High Grade in the productive list. The Modoc mine is in good ore on the 50-ft. level, where they are extracting \$200 to \$400 ore from a body 6 or 7 ft. thick. A large contract has been let for winter's wood for the hoist, the only one here. Lately officers of the Company visited the property and were pleased with the progress being made. Orders were given to extend the work on the 50, 100, and 200-ft. levels. There is a commodious shaft-house containing boiler, pump, and hoist, and a blacksmith-shop adjoins. A fully equipped assay office is in charge of George Kline.

C. H. Miller & Detweller, lessees on the Sunshine prop-

SKETCH MAP OF HIGH GRADE DISTRICT.

erty, are sinking a winze from the main level. They have an ore-shoot running from 8 in. to 2 ft. wide, much of which shows gold. The ores averages \$60 to \$80. Lessees are expected to start work on the north drift soon. Some very high assays were secured on this property when first opened, and the present work should show good results as the ground is developed. Fred Sahrott, lessee on the Yellow Jacket, has a nice body of ore opened on the south face of the mountain, with a drift on the vein from a shaft about 40 ft. deep. A shipment to the smelter has just been made.

The Big Four company has given a lease, but will also do considerable development work. The orebodies on this property are large and range in value from \$450 to \$200 per ton. There are a 5-stamp mill, several adits, a shaft over 100 ft. deep, with another about 30 ft. deep. The Alluros property has a shaft 110 ft. deep, from which a cross-cut to the east has been driven to intercept a vein being worked on an adjoining property. The ore is principally a sulphide, assaying \$68 per ton. While few men are employed at the Gold Shore property to the east of the Sunshine, an adit is being driven steadily to cut the vein which crosses the ground and from which float ore assaying over \$400 per ton was taken. A shaft sunk on a cross-fissure gave assays of \$15 to \$35. The Brodus or Evening Star group has done much surface work and a quantity of ore has been exposed on the Klondike vein. There is a shaft over 20 ft. deep and a number of open-cuts in ore worth \$20 per ton. Richer ore has been found as float. The Consolidated property will soon be working

a number of men, the order having been given to extend the present level or main adit on the Mountain View. The equipment here includes a 5-stamp mill and 1000 ft. of aerial tramway from the Sugar Pine tunnel to the mill.

At the Griffith mine the shaft has been deepened and is in ore of a high grade. Some of this shows black manganese and hematite with coarse gold. The body is 1 to 2½ ft. wide. The shaft is protected by a shaft-house and blacksmith shop. The O'Connor property is steadily being developed by two cross-cut adits which will intercept the veins at 600 and 1500 ft. depth. This will, when developed, make one of the largest properties in the district and, judged by the veins at the surface, gives promise of some ore. The property includes a millsite, and all conditions favor large operations.

The Fox property has an adit driven 300 ft. to cross-cut the veins. Some work is yet necessary before the ore will be reached, which will be at about 250 ft. depth. The Coombs property has a nice showing of ore in an adit, which cuts the veins at about 100 ft. depth. The value is from \$40 to \$50 per ton. The Discovery group is being developed by opening new veins, and some rich finds are being made as the work progresses. This property, the original one of the district, under proper development should make a fine property. Very rich ore is to be found at the surface and in a shaft of 20 ft. depth. Several hundred feet of exploratory adits and drifts have been driven. The Sunset group is being steadily worked through a drift run from a main adit. A small quantity of ore is in sight. Some work is being done on an out-crop which gives promise of rich ore. One of the latest discoveries was on the Baty group, on the Eugene claim, where coarse gold was found at the surface. Sinking to determine width and direction of the vein has been in progress, and an adit on the Luckyboy will be driven to intercept this vein. The ore is of high grade as indicated by panning.

On the west side of Mt. Vida considerable work has been done by Snider and Lynch, who have driven an adit 150 ft. in rich ore which pans high. They are developing their ground. Nance and Callahan have claims adjoining and are sinking a shaft on ore of much promise. On over 20 prospects the work has been done for the year, and all indicate a value up to the average of the district. I have personally visited all the properties being worked, also several of the prospects, and made my own selection of ore and pannings, and find values verifying those given at the several properties. The gold is mostly fine and crystalline in structure. At the Brodus property the size was somewhat coarser, and on the Baty property a little coarser than on the Brodus. Whatever the sulphides show, an average of ¼ to 2½% is indicated. Assay values of 5 gold to 1 silver have been the average on all ore mined. Preparations have been made to continue work throughout the winter at the several properties. The economic conditions of High Grade should make this camp one of the great producers.

MELBOURNE, AUSTRALIA

BROKEN HILL SOUTH.—A BENDIGO MINE.—ANOTHER OSMI-
RIDIUM DISCOVERY.

The half-yearly report of the Broken Hill South Silver Mining Co. presents some unpleasant features, despite the fact that a net profit of \$554,000 was made. Big as it is, that does not compare favorably with the profit of \$1,028,000 made in the previous half-year, out of which dividends of \$824,500 were paid, and this year, with but little more than half the profit, the amount paid was \$776,000; that is to say, \$222,000 more than was earned. A main cause of the decrease in profits is the decline in the prices of metals. This has had a marked effect upon the revenue from the sale of lead concentrate, the Company's chief source of income. But the decline in the metal market is by no means the only cause of the Company's present position. There was also a reduction in the output of ore, though this was to some extent offset by an improvement in the grade treated, and also in the recoveries. Another source of trouble has been the rise

In costs, development costs in the mine having advanced as much as 132.5% in 12 months, while the advance in total working costs has amounted during the same period to 15%. The sinking cost totals \$34 per ton of concentrate.

The South New Moon mine, one of the leading Bendigo producers, has paid dividends totaling \$2,425,000. The Company was formed in 1871, but its first dividend was not paid till 1890. The amount of assessments on the 32,000 shares owned has been almost \$4.25 per share, and the dividend paid about \$72 per share. The equipment expenditure has amounted to less than \$100,000, and the output has been 381,324 tons yielding 223,891 oz. of gold, exclusive of residue.

In the issue of July 26 mention was made of an osmiridium discovery on the west coast of Tasmania. Now another one, two miles distant, but in the same line of country, is reported. The prospectors claim that the osmiridium occurs in a lode, but that is a matter on which one may well be more than skeptical. If it be a lode formation, then something unique has been discovered, and a tremendous impetus should be given to the use of the metal, the price of which has been fast increasing of late.

NEW YORK

THE COPPER SITUATION.—MINING IN MEXICO.—AMERICAN INSTITUTE OF MINING ENGINEERS DISCUSSES IRON AND STEEL PROBLEMS.

The announcement that the miners at Rio Tinto have struck makes the copper situation still more interesting. The output at Rio Tinto is about 6,000,000 lb. per month, and this is a considerable amount, superimposed on the 12,000,000 lb. or so which is still lacking from the normal Lake Superior output. It is the latest of a series of events which have conspired to help the sellers of copper, and apparently they have needed its aid, for the metal exhibits little sign of going above 17c., even with the decreases in the supply and the heavy European demand. Progress is being made toward the settlement of the strike in Lake Superior, and a committee of mine-managers has stated to the Copper Country Commercial Club that the 8-hour day will be introduced before the end of this year, and a time will be set each week for the making of complaints by the operating force. On the other hand, the one-man drill must be retained, a minimum wage scale will not be adopted, and the Western Federation will not be recognized. The companies are making fair progress in getting men, and it is to be expected that within a comparatively short time the strike will be settled on essentially the lines mentioned. The Utah Copper Co. produced 11,817,428 lb. copper during September, and has been steadily breaking record after record of output. This and other companies are making hay while the sun shines. Last year at this time, Utah Copper was shut down by a strike and the copper production for the fourth quarter of the year was very small, but now it is making up for it.

The American Smelting & Refining Co. is badly hampered in Mexico. The smelting plant at Chihuahua is running at about 80%, that at Aguascalientes at half, and the Monterrey plant at one-third capacity. The plants at Matahuala and Velardena are shut down, but are in shape to resume work when railroad traffic can be restored. Some of the companies in northern Mexico are not at all disturbed; at El Tigre, for example, operations are in full swing. The Teztlutlan Copper Co., in Puebla, has had to shut down, while, on the other hand, the Mexican United Co., in Guanajuato, has started sinking three shafts, and the Mexican Mines, Ltd., has resumed operations after having been shut down for some time. The San Toy, in Chihuahua, has been steadily at work since June last.

The autumn meeting of the American Institute of Mining Engineers, held in New York on October 16 and 17, was devoted to the discussion of papers on iron and steel, and was under the auspices of the iron and steel committee, of which Albert Sauveur is chairman. The first session was held in the United Societies building, 29 West Thirty-ninth street, at 10 a. m. on October 16, Mr. Sauveur in the chair.

The first paper read was by W. A. Forbes, on blast-furnace gas cleaning. This was followed by a paper on the slagging gas producer, by W. H. Blauvelt, which evoked good discussion. Then followed a paper on the generation of steam by waste heat from furnace gases, by F. Peter, read by the secretary, Bradley Stoughton. A brief paper on the same topic by George C. Stone, giving the result attained at the Palmerton plant of the New Jersey Zinc Co., followed, and the two were discussed together, bringing out some interesting comparison with practice at other places. The concluding paper of the morning session was by W. R. Shlmer on over-oxidation of steel. This provoked animated discussion, in which H. M. Howe, A. S. Cushman, and a number of others joined. At noon, lunch was served in an adjoining room, and the social hour thus afforded seemed to be as highly appreciated as the technical sessions. The first paper of the afternoon, at which J. W. Richards presided, was by Richard K. Meade, on the use of pulverized coal as fuel. This was a statement of practical conditions, and was followed by a more general paper on the same topic by H. R. Barnhurst. W. S. Qulgey also contributed a paper on the same topic. The discussion was general and excited much interest. This was followed by two papers on briquetting practice, by E. Stuetz, and F. A. Vogel, which also called forth good discussion.

The session on the morning of October 17, at which Mr. Sauveur presided, was chiefly devoted to the three papers by H. M. Howe discussing A₂ and A₃ in carbon-iron alloys which naturally evoked much interest and called forth good discussion. G. K. Burgess and J. J. Crowe presented a paper on this topic, and also a paper on the thermal and microscopic examination of steel. Luncheon was served at noon, as on the preceding day. At the afternoon session Dr. R. W. Raymond presided, and the paper by W. A. Ruder on grain growth in silicon steel, carried over from the morning session, was presented. This was followed by a discussion of the effect of various elements on the absorption of carbon by steel, by R. R. Abbott, presented in abstract. Lively discussion was evoked by a paper by J. H. Hall, on shock tests of cast steel, though another paper by the same author on the life of crucible steel furnaces was not so thoroughly discussed. A paper by G. H. Clevenger and B. Ray on the influence of copper on steel was presented in abstract by D. A. Lyon. This led to good discussion, in which A. S. Cushman took a leading part, giving the results of tests on 60-ton lots, which generally confirmed the results obtained by the laboratory study of Messrs. Clevenger and Ray. The meeting was concluded by an informal subscription dinner at the Engineers' Club, where only about 60 members and guests were present, the date conflicting with the dinner and evening session of the New York section of the Electrochemical Society.

COBALT, ONTARIO

MINERAL PRODUCTION OF NORTHERN ONTARIO.

The first official report since 1908 on the silver, cobalt, nickel, and gold mines of northern Ontario has just been received. W. G. Miller, who compiled the report, states that the Cobalt district, besides being one of the world's most productive silver areas, controls the market for cobalt and arsenic and is among the three or four areas that have the largest output of nickel. As a general rule, however, these ores are so complex that the nickel is not saved in the smelting process. Statistics show that up to the end of 1912 the Cobalt mining district has produced 155,815,839 oz. of silver, valued at \$81,731,115. The quantity of cobalt, nickel, and arsenic produced cannot be determined. Up to the end of 1912 the total dividends from the mines amounted to \$39,834,740, without including the profits from two or three privately owned companies. This is approximately 50% of the value of the output and constitutes a unique record. If the dividends for the present year are added, the total distribution will be approximately \$45,000,000. It is interesting to note that the discoveries in the Cobalt district were directly due to the building of the Temiskaming & Northern Ontario railway, and that while the railway cost only \$18,500,000, the mines have paid \$45,000,000 in dividends.

General Mining News

ALASKA

VALDEZ

The Granby Consolidated company, of British Columbia, has purchased the Midas mine at Solomon gulch, near Valdez, for \$123,000. The first cash payment of \$25,000 was made at Valdez on October 1. The property was staked in 1900 and has passed through several hands. Development has covered about 1800 ft. to date, and a large tonnage of ore averaging 4% copper and \$2 per ton in gold and silver has been blocked out.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—The Copper Queen company is erecting a new hoist on Copper Queen mountain near the postoffice. The head-frame is complete. Development by the Higgins Leasing Co., on property above the postoffice, is full of promise. J. Letson is in charge. The Wolverine & Arizona Mining Co., with W. Roberts in charge, is also opening satisfactorily. New stations and ore pockets are being cut on the 1600 and 1700-ft. levels of the Calumet & Arizona Junction shaft. At 1800 ft. a large pumping plant is to be installed. W. Gohring is mine superintendent. About 300 tons of lead ore is being shipped weekly to El Paso from the Shattuck-Arizona mine.

Bisbee, October 16.

GILA COUNTY

(Special Correspondence.)—At the Arizona Commercial mine sinking to the 1400-ft. point has been commenced. A carload of ore has been shipped to the Old Dominion smelter No. 3. In a cross-cut 50 ft. of vein has been opened to date and 31 ft. of it is in ore. The face of the cross-cut at 50 ft. was also in ore. The ore will average about 6% copper and contains a heavy content of iron. At the Iron Cap, stoping is being carried forward on No. 8 level. Seventy-five feet remains to be driven on the 650-ft. level before connection with the Eureka shaft of the Arizona Commercial is established. Shipments this month will exceed those of September.

Underground work continues at the Inspiration and new headings are being started. Although the Joe Bush orebody has all been blocked out and ready for caving, it is expected that this shaft will soon be in operation again, as a new electric hoist has recently been installed. On the fourth level the drift to the main shafts has now reached a point opposite the two shafts and as soon as the stations are cut at these shafts the Inspiration company will have underground connection with all of its workings on the Inspiration division. Considerable work is being done in the way of preparations for sub-levels in the Colorado orebody.

Globe, October 17.

Developments at the Arizona Commercial are satisfactory according to a recent report. Twenty-five feet of good grade sulphide ore was cut in No. 3 cross-cut; then a talc seam cut off the ore, but after getting through talc it went through 5 ft. of good sulphide and is still in it. Sinking has been started to No. 14 level, and drifts are now being opened on No. 7, 10, and 12 levels. Development to date indicates the large size and permanency of the orebodies.

MARICOPA COUNTY

A fair tonnage of \$40 ore has been opened in the Mammoth mine, 16 miles northeast of Mesa. At the mill, 10 of the old 20 stamps have been put in order. The cyanide plant consists of three 60-ton steel leaching vats, weak and strong solution tanks and sumps, and 12 zinc-boxes of the movable type. The Buffalo-Arizona company, near Morriston, is shipping rich gold ore to the Douglas smelter.

YAVAPAI COUNTY

Work is to be restarted at the property of the Monarch Mining & Smelting Co., near Wickenburg. The Ophir claims are to be thoroughly developed by A. J. Kent. At the Monte Cristo, new shafts are being sunk. A large mineralized dike is being prospected by E. Block on the Sink to Rise claims.

High-grade silver ore is being shipped from the Humboldt mine. At the Eureka, in the Walker district, 400 tons of \$45 gold ore is on the dump. The ore also contains zinc. Gold, silver, and lead ore has been opened in the Pioneer, near Walnut Grove. The adit has been finished at the New Year's Gift mine.

CALIFORNIA

AMADOR COUNTY

The suit between the Kennedy Extension and Argonaut companies is still being heard at Jackson. At the present time there is considerable activity in the county. The Zeila mine will probably be sold. The cross-cut from the Oneida to the South Eureka was completed last week, the length being 3200 ft. Sinking at the Central Eureka has been completed and cross-cutting is being done. An adit is being driven to prospect the West Eureka property, and \$5 to \$7 ore has been opened. The Wildman-Mahoney mines are inactive, and the Keystone is being prospected by C. R. Downs. At Drytown there is some work being done at the Little Illinois, and a tube-mill has been installed in the mill. The Empire-Pacific and Alpine at Plymouth are being worked. Regular mining and milling continues at the Kennedy, Argonaut, Zeila, Original Amador, Bunker Hill, and Fremont-Gover.

BUTTE COUNTY

In order to centralize control of the various dredging companies operating at Oroville, the following will be merged in one company: the Boston & Oroville Mining Co., Boston & California Dredging Co., Continental Gold Dredging Co., Oroville Gold Dredging & Exploration Co., and the Bear River Mining Co. These companies will be voluntarily dissolved and their properties will be deeded to the Oroville Dredging, Limited.

NEVADA COUNTY

The North Star Mines Co. has declared its third dividend of the present year, amounting to \$50,000, at the rate of 20c. per share. This makes \$150,000 distributed to stockholders in the first nine months of 1913, and it is confidently expected that a fourth dividend will be disbursed in December. The last dividend brings the grand total of profits paid to North Star stockholders to \$3,936,898, on a capitalization of \$2,500,000. The steady disbursement of dividends has been maintained despite the money set aside for the development of the Champion mines at Nevada City and financing of other projects in the Grass Valley field.

PLACER COUNTY

The hull of the dredge for the El Dorado & Placer Counties Gold Dredging & Power Co. is complete, and is to be launched in a few days. The Great Western Power Co. is stringing the power-lines for the motors.

The Pioneer Gold Mines Co. has been incorporated with a capital of \$1,000,000 in \$1 shares. The directors of the Company are E. McLaren and M. F. McShane of San Francisco, T. H. Minto of Corte Madera, R. C. Smith of Berkeley, and L. Linderman of Oakland. The above Company is the one that recently purchased the claims of the Pioneer mine situated near the junction of Humboldt cañon and the North Fork, and worked for many years by J. D. Sullivan and his son Jerry Sullivan.

Rich ore containing arsenical pyrite has been opened again by A. R. Seymour in the Independence mine on Winters creek. The vein is 12 in. wide.

SHASTA COUNTY

There are 150 men employed at the Gladstone mine, and the shaft is now in good order for its 1100 ft. depth. Three asbestos claims have been located west of Hazel creek near the Trinity-Shasta county line. Several months ago 30 claims were located on Mears creek.

SISKIYOU COUNTY

The Isabella Copper Mining Co. is mining copper ore from a large vein in its mine 18 miles from Gazelle.

TRINITY COUNTY

(Special Correspondence.)—The State Mining Bureau has an engineer studying mining conditions in the East Fork

district of the county, this being the first time for nearly twenty years that an examination has been made. The area is exceedingly promising, well timbered, good water and climate, an interesting field for the geologist, and good opportunities for capital in the many gold-bearing veins being prospected.

Carville, October 18.

The water-supply of Lagrange hydraulic mine is being improved by the laying of a new pipe-line from Stewart's fork of the Trinity river to the gravel deposits. It is expected to have the work completed within a few weeks, before the heavy winter storms set in. Considerable repair work has been performed around the mines, ditches, and flumes during the past few weeks, and everything placed in readiness for the usual winter activities. The Trinity River Consolidated Co., the second largest hydraulic operator in the county, has also been busily engaged in completing preparations for the winter. Placer miners throughout the county are actively placing their claims in shape for vigorous production with the advent of the rains, and from all indications the coming winter will be the busiest for some time.

TUOLUMNE COUNTY

The Johnson ranch has been bonded by L. H. Elliott for the Springfield Flat Development Co., which will develop the gravel deposits in the Springfield basin, by a 6000-ft. adit. A. L. Horner is superintendent.

COLORADO

LAS ANIMAS COUNTY

Forty-nine striking miners, charged with picketing, were arrested at the McLoughlin mine of the Santa Fe Coal Co. and marched three miles to the county jail at Trinidad. Fifteen deputies, armed with rifles, flanked the prisoners on either side, and a machine gun, mounted on an automobile, brought up the rear, but in spite of this, several members of the crowd of 300 strikers that followed the party attempted to break through the lines and liberate the prisoners.

OURAY COUNTY

A custom zinc plant has been built at Ouray by David Forrester for handling the middlings from the various concentrating mills of that district. It is equipped to handle 20 tons per day and has been operating since the fall of 1912. Some of the ores treated come from the Atlas, Barstow, Camp Bird, and Mickey Breen mines. The following results indicate the feed treated by the Huff electrostatic method, according to Frank S. Macgregor:

	Class 1.	Class 2.	Class 3.
Gold, ounces	0.11	0.13	0.20
Silver, ounces	59.30	13.00	11.00
Lead, per cent	6.90	7.00	1.95
Copper, per cent	0.80	1.90	2.50
Zinc, per cent	25.40	28.30	14.70
Iron, per cent	16.90	22.00	30.50
Insoluble, per cent	19.60	2.00	5.60

TELLER COUNTY (CRIPPLE CREEK)

On October 26 the Mary McKinney Mining Co. will pay a dividend of 2c. per share, amounting to \$26,185, making a total to date of \$1,090,751. Orebodies on the 900 ft. level are producing good ore.

The main shaft of the Strong Gold Mining Co., situated at the Strong mine, on the southern slope of Battle mountain, near to the boundary limits of the city of Victor, has been sunk to a depth of 1200 ft., where the water-level was reached an elevation of 8556 ft. above sea-level. A station is now being cut at this point.

IDAHO

SHOSHONE COUNTY

Net earnings of the Stewart Mining Co., operating near Kellogg, were \$95,000 in September.

The following is the itinerary of the Bureau of Mines mine-rescue car Billings No. 5: October 17 to 24, at Burke; October 24 to 31, at Mace; November 1 to 8, at Morning mine; Mullan; and November 9 to 18 at Hunter mine, Mullan. From here the car will go to Phillipsburg, Montana.

MICHIGAN

HOUGHTON COUNTY

Eviction notices on striking miners in houses owned by the Champion Copper Co. at Painesdale were served on October 16, and similar action is said to be contemplated by the Calumet & Hecla Mining Co. at Calumet.

(Special Correspondence.)—Mention was made recently that the Copper Country Commercial Club was to investigate the strike. Its report of 76 pages of details of the mining industry and 26 pages of illustrations has now been issued. In summing up its conclusions, the committee finds that the mine managers will not recognize the Western Federation of Miners, that no minimum wage scale can be applied in justice to all of the mines; that the one-man drill has come to stay; that the eight-hour working day will be in operation in every mine in this district by next January; that a system for grievance and complaint hearings will be arranged, the mine managers agreeing to set aside a day or half a day each week for that stated purpose, agreeing also to investigate and adjust every legitimate grievance with all possible speed; that no discrimination will be made against men presenting complaints. On the day that the report was issued, October 8, there were 5445 men at work, against 14,300 in all occupations just prior to the strike. These latter included from 23 at the Oneco to 4107 at the Calumet & Hecla. The wages paid during 1912 amounted to \$12,606,409, so that in normal operations the men receive over \$1,000,000 per month.

One of the most interesting features is an actual table of wages including every mine in the district for a six-month period just previous to the strike. These figures are taken from the company books. They show the average wage for all mines to be \$3.20 per shift for miners, \$2.63 for trammers, and \$2.98 average for both miners and trammers. Another table taken from the books of the Calumet & Hecla subsidiaries shows the average wage of miners for the month of May this year to be \$3.47, of whom 14% were drawing over \$4 per shift and the same percentage under \$3, running from \$2.50 to \$3. A similar table on trammers' wages from this corporation and subsidiaries shows an average of \$2.83. The average for miners on the conglomerate lode is \$3.67 and contract trammers \$3.40.

Houghton, October 12.

During October the Victoria company will break ground for a new working shaft at a point 1200 ft. east of the so-called No. 2 shaft, which, practically since organization, has been the sole producing shaft open in this area. The new shaft will sink in ground already proved by drifts on several levels run out from the present working shaft. The monthly copper output is about 250,000 lb. The Keweenaw Copper Co. has completed drill holes No. 47 and 48, on the Ashbed lode, in the western limits of the property; and the drills are being moved to new positions, east of Mosquito lake, nearly seven miles distant. The showings obtained in the borings made in the west area are quite satisfactory.

MONTANA

BLAINE COUNTY

(Special Correspondence.)—The cyanide plant of the Ruby Gulch Mining Co., in the Little Rockies, was entirely destroyed by fire on August 7. As the Ruby Gulch property was the only active one in the district at this time, the loss of the mill was particularly unfortunate.

Butte, October 20.

GRANITE COUNTY

(Special Correspondence.)—The Royal Basin Mining Co. reports an important development in its lower adit. The vein contains 7.5% copper and from 5 to 70 oz. of silver per ton over a width of several feet.

On his ranch near Maxville, J. D. Fields claims to have opened a bed of phosphate rock, 5 ft. thick, which will assay 77% tricalcic phosphate. Mr. Fields is said to be negotiating with Japanese importers for the sale of the output.

Maxville, October 20.

JEFFERSON COUNTY

Mine-rescue car, Billings No. 5, of the Bureau of Mines, will be at Elkhorn from December 17 to 23.

POWELL COUNTY

(Special Correspondence.)—The U. S. Geological Survey has had a geological party in the vicinity of Elliston during the past season, outlining the boundaries of the rock-phosphate deposits. It is claimed that the work done was satisfactory, and that good-sized commercial beds of phosphate rock were found and mapped. These deposits all occur in strata of the Pennsylvanian (Quadrant) period. Elliston, October 20.

Mine-rescue car, Billings No. 5, of the Bureau of Mines, will be at Philllipsburg from November 20 to 28.

SILVERBOW COUNTY

Mine-rescue car, Billings No. 5, of the Bureau of Mines, will be at Butte from November 30 to December 16.

NEVADA

CLARK COUNTY

(Special Correspondence.)—A. W. Geiger has been examining properties at Searchlight and Hart for the California Ore Testing Works and has shipped a large number of samples to San Francisco. At Searchlight, interest centres in the work of Jonas & Miller at the old Quartette property, from which occasional shipments of ore worth \$150 to \$300 per ton are being made. At Hart, the free-milling ore extends to a depth of about 800 ft., and while the mines are only about four years old a considerable tonnage has been developed.

Searchlight, October 20.

HUMBOLDT COUNTY

(Special Correspondence.)—An examination of the properties of the Rochester Mines Co. with a view to their purchase by the Guggenheim interests is in progress at Rochester. It is said that an initial payment of \$50,000 will be made on the conclusion of the examination if the sampling is satisfactory. The money and five men experienced in making such tests have been sent out from Salt Lake City. Information to the effect that the Nenzel and Cowan interests, controlling more than 500,000 of the 700,000 issued shares of the Rochester Mines Co., are the vendors in the prospective deal, and that the total price to be paid is about \$1 per share. Salt Lake City capital is interested heavily in the Queen of Sheba and De Soto properties, west of Rochester camp, and these people promise a revival of activity in that old mining district within the next three or four months. Both of the old mines are now under lease.

Rochester, October 15.

LINCOLN COUNTY

On October 12 a fire destroyed \$100,000 worth of property in the business portion of Pioche. Help from the Prince Consolidated mine prevented its spreading farther.

NYE COUNTY

The mines at Tonopah, during the week ended October 18, produced 11,832 tons of ore valued at \$278,960. In September, 11 mines yleided a total of 47,745 tons having a gross value of \$937,720, a decrease of 5437 tons and \$108,880 respectively, compared with August, due to a holiday and storms. Individual outputs are as follows:

	Tons.	Value.	Profit.
Beimont	13,000	\$271,423	\$182,906
Extension	4,847
Jim Butler	1,426	8,507
MacNamara	2,387
Merger	2,309	36,282	11,500
Montana	4,496
North Star	1,757
Tonopah	13,150	207,520	110,400
West End	3,948	45,198

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Socorro mill treated

5700 tons of ore in September yielding approximately 70,000 oz. bullion. High-grade concentrate was shipped. The mine is opening splendidly. The Deadwood mill is working full time, and 6375 oz. bullion was melted from a 10 days' run. At the Ernestine mine good progress is being made in shaft-sinking. The Pacific mine is yielding \$15 ore. No. 1 winze of the Lincoln is being sunk 10 ft.

DEADWOOD MINE AND MILL, KNOWN AS THE 'DEADWOOD SCHOOL OF MINES.'

per week in spite of water troubles. Work has been resumed at the Alberta. Lessees at the Oaks property report good results.

Mogollon, October 13.

PENNSYLVANIA

(Telegraphic Correspondence.)—Attendance at the opening session of the American Mining Congress Monday was disappointingly small, but the numbers and enthusiasm increased through the week. The presidential address of D. W. Brunton dealt with the need of revision of the mining laws; E. B. Kirby, chairman of the committee on this subject, reported a growing approval of the plan of having a congressional commission for revising the law. Tuesday there was an interesting discussion of mine taxation, participated in by R. V. Norris, H. M. Chance, H. H. Webb, B. W. Vallat, J. W. Malcolmson, and C. E. van Barneveld. In the afternoon there was an excursion on the river. The Mining Show contained numerous interesting exhibits, especially the coal mining machinery. The U. S. Bureau of Mines rescue team gave excellent exhibitions of mine rescue work. Among papers presented was one by C. R. Van Hise strongly urging an Interstate Trade Commission to permit and regulate trade agreements; a project of especial interest to bituminous coal mine operators.

Philadelphia, October 22.

UTAH

The production of gold, silver, copper, lead, and zinc in Utah in 1912 from 7,770,270 tons of ore from placers was valued at \$42,922,302, an increase of \$6,084,845, as compared with 7,268,530 tons of ore in quantity and \$36,837,457 in value in 1911 from deep mines and a nominal placer yield. There were 207 properties, 9 of which were placers, producing ore and bullion, as against 200 iode producers and 8 placers in 1911. Over one-half of the total value in 1912 represented the copper production, which was valued at \$22,655,735, an increase of \$4,285,632 as compared with the production of 1911. Increases in total value were made in all the other metals except gold, the yield of which was \$431,147 less than in 1911. Salt Lake county had the greatest total value for its metal output, which increased from \$22,561,615 in 1911 to \$24,684,132 in 1912. This was chiefly due to the higher price of copper in 1912, as all the metals produced in the county decreased in quantity as a result of the labor strike. Concentrates recovered from ores at milling plants in 1912 contained 21.4% of the gold against about 22% in 1911; 20.1% of the silver, against 19.8%; 76% of the copper, against 73%; 33% of the lead, against 34%; and 63% of the zinc, against 74% in 1911. In 1912 the concentrates were valued at \$22,781,896, or an average value of \$59.74 per ton, as against a total value in 1911 of \$18,633,465

and an average value of \$52.14 per ton. Crude ores shipped directly to smelters yielded 67.3% of the gold in 1912, as against 63.8% in 1911; 78% of the silver, as against 79%; 23% of the copper, as against 26.3%; 63% of the lead as against 65.6%; and 37% of the zinc, as against 26.2% in 1911. In 1912 the total value of the crude ore shipped to smelters was \$19,188,571, or an average value of \$18.51 per ton, as against a total value in 1911 of \$17,364,933, or an average value of \$15.74 per ton. At gold and silver mills, 10.3% of the gold and 0.46% of the silver was recovered from ores treated principally by the cyanide process, valued at \$479,724, or an average value of \$2.80 per ton. The placer production of gold increased slightly, and was valued at \$5680, as against \$5634 reported in 1911. Statistics of the average annual production from 1904 to 1912, inclusive, are shown in the following table, according to V. C. Heikes of the U. S. Geological Survey.

Metal.	Quantity.	Increase or decrease.
Gold, value	\$4,265,851	— \$431,147
Silver, ounces	13,835,903	+ 1,362,116
Copper, pounds	137,307,485	— 9,653,342
Lead, pounds	140,311,135	+ 3,814,385
Zinc, pounds	17,067,177	— 773,084
Total value	\$42,922,302	+ \$6,084,845

SALT LAKE COUNTY

(Special Correspondence.)—Being in need of machine-drills and other labor-saving equipment, the stockholders of the Alta Consolidated Mining Co. recently voted to increase the capital stock of the Company from 300,000 to 500,000 shares. All the work done in the last two years was by hand, and most of the ore was hauled 22 miles by teams. Since the summer, the Alta has been using the Michigan-Utah tramway, which passes its dump. The Michigan-Utah company is shipping again from its Utah Mines Coalition workings, and has five leasing companies mining in its City Rocks property. The Montana-Bingham tunnel, designed to be 4000 ft. long, is about half done. It is making 150 ft. per month. In six months the bore has passed through about 300 ft. of ore averaging 1.25 to 1.5% copper, 80c. gold, and 3 oz. silver per ton. The Utah Copper is handling about 25 tons of capping to 30 tons of copper ore, with its steam-shovels. A record of 30,000 tons of ore was made one day recently. Salt Lake City, October 12.

A considerable amount of new equipment is being added to the American Smelting & Refining Co.'s plant at Garfield. A steel bridge over the railroad to the north of the smelter leading to the slag dump north of the old dumps has been erected at a cost of about \$75,000. This gives a much larger slag-dumping area. Preparations have been made for a stack and new flues. The former will be 350 ft. high, and 25 ft. diameter, against 300 and 30 ft., respectively, at present. All the reverberatory furnaces are being fired with oil. Copper ore and concentrate are coming in from the Yampa, Ohio, Utah, and other copper companies.

At the Midvale plant of the United States Smelting, Refining & Mining Co., a Huff electrostatic plant has been in continuous operation since 1909, saving 5,000,000 to 7,000,000 lb. of zinc per year, which heretofore had gone to waste, according to Frank S. Macgregor. This plant treats about 50 tons per day of zinc-iron middling, part of which is furnished by the Company's concentrator and part from custom ore from the district. The work has been uniform since the beginning. The feed to the mill assays approximately 0.04 oz. gold, 2.5 oz. silver, 2.5% lead, 1% copper, 23% iron, and 28% zinc. The separated zinc product assays 48 to 50% zinc, with 3 to 5% iron, and the iron product about 10% zinc. Most of the gold, silver, copper, and lead is found in the iron product, and this product is smelted in the Company's lead furnaces. Four sizes are made in the mill, ranging from 20 mesh down. The feed to the fine-crushing machines often runs more than 50% through a 200-mesh screen.

During September the Ohio Copper Co. produced 685,900 lb. of copper from about 71,000 tons of ore containing 1.06% copper.

WYOMING

LARAMIE COUNTY

It is reported that the Hecla copper mine, 25 miles southwest of Cheyenne, has been acquired by French and English interests. Henry Schwartz, of Denver, Colorado, will continue to act as president of the Hecla Consolidated Mines Co. The property consists of 600 acres and has produced copper ore for the last fifteen years, according to the *Colorado Springs Gazette*.

CANADA

ONTARIO

The Trethewey mine at Cobalt produced 56,400 oz. silver in September from 2900 tons of ore, with 82% recovery. A winze below No. 2 level of No. 4 shaft is yielding rich ore. At the Casey-Cobalt mill 30 stamps are working crushing 90 tons of ore per day. Electric power is supplied by the Montreal river power-plant.

In a smaltite vein in the diabase at the Millerette mine, assays have returned 3 to 34 oz. gold per ton. No economic importance is attached to the discovery, but from a metallurgical point of view it is interesting. The specimens from which the high assays are obtained contain no visible gold. Two hundred feet distant in the same formation, high-grade smaltite is found. The gold ore is found in a belt of silver veins which have been opened this summer on the Millerette mine which last February passed into the possession of M. J. O'Brien, the owner of the Miller Lake O'Brien mine and adjoining property.

YUKON

Two unknown men held up the hydraulic employees at the Yukon Gold Co.'s property at Lovett gulch on October 2, cleaned-up part of the sluice-boxes, and escaped with about \$20,000 of gold. The Company had not cleaned-up this place all the summer, and had intended doing so on the day of the robbery.

COSTA RICA

The Abangarez Gold Fields of Costa Rica reports that during August there was treated 6800 tons of ore, 619 tons of sand, and 5572 tons of slime, yielding \$12,579 by amalgamation and \$53,921 by cyanidation. The profit was \$12,208 and \$4399 was spent on improvements.

MEXICO

CHIHUAHUA

During August the Buena Tierra mine was worked 26 days, yielding 3000 tons of lead ore, of which 2600 tons was sold to the smelters. The net return was \$15,600 from this ore, and \$6350 was spent at the mine.

COAHUILA

According to the *Mexican Herald* of October 3, the Carrancista rebels of the northeastern portion of this state have done enormous damage to the coal mines of that district, especially at the Lampacitos and Rosita properties, others being Las Esperanzas, Agujitas, Cloete, El Menor, Palau, Fiente, Diaz, Fenix, and Rio Escondido. Practically the whole region is paralyzed and 11,000 men are out of employment. The Matehuala smelter is still shut down.

GUANAJUATO

Mining operations throughout the state have not suffered much on account of revolutionary movements or marauding bands of rebels. There are good prospects that work will be resumed in various mines, that have lain idle for some time, and also that new properties will be opened. During the past week shipments from Guanajuato to the smelters were worth approximately \$61,500. Regular weekly shipments of about 80 tons of ore are being made to local buyers from the Calicanto and Anexas mines, owned by Fernando Rubio Rocha and Manual Aranda, situated between Mineral del Cubo and Nayal. The ore yields from 150 gm. of silver and 15 gm. of gold to 250 gm. of silver and 25 gm. of gold per ton. The properties are being developed by a 6½ by 6½-ft. adit, 1500 ft. long. Pumps have been installed to unwater three shafts.

HIDALGO

The Cortez Associated Mines Co. has an authorized capi-

tal of 500,000 shares at \$3 each, of which 275,000 have been issued, and is incorporated under the laws of West Virginia, and operates mining properties at Jacala and Zimapan. The report covers the year ended April 1, 1913, when work was discontinued indefinitely, although during the year there was no direct interruption from revolutionary disturbances. At the date of the report, openings in new ground at Jacala covered 21,458 ft., not including 2465 ft. of core-drilling, the Cortés and Humboldt adits being 1770 and 1304 ft. long respectively. Several large deposits of low-grade copper ore and some rich ore were opened, as well as silver-lead ore in the Encino Largo mine. The old Carmen mine was almost reopened and connected with the new main winze. At Zimapan, prospecting has confirmed previous estimates of the properties, and the Sirena lead-antimony deposit is of great size and richness, and contains 18.89% lead, 12.87% antimony, 4.20% arsenic, and some gold and silver. There were 263 men employed, and the average monthly development covered 662 ft., this costing \$5.593, and core-drilling \$1.307 per foot.

The report contains the summary of an examination of the properties by Waldemar Lindgren, made in February and March, 1913, who stated the following: Zimapan is 85 miles north of Mexico City, and Jacala is 35 miles from the former place. Mining and smelting has been carried on at both places for centuries, there being three small lead smelters at Zimapan at present. Water is scarce at Jacala, but can be obtained by pumping, while timber is abundant nearby, but at Zimapan the country is arid. Thick beds of blue limestone form the prevailing country rock at Jacala. Along the contacts of the main masses of intrusive igneous rock deposits of copper and silver-lead have been formed. The Cortés adit has developed 35,000 tons of 1.72% pyrite ore, and about 100,000 tons of low-grade ore is available at the Santa Maria and Gallo and Humboldt deposits. Under present conditions these ores cannot be profitably mined at Jacala. The Carmen mine is the most important property, and a shoot of silver-lead ore, forming a replacement in limestone, has been followed on the incline for 900 ft., producing over \$500,000. Zimapan lies in a broad arid valley surrounded by mountains, and the ore deposits are replacements in limestone. It is difficult to estimate the ore reserves, and there is 3000 tons of ore on the dump and 2000 tons in the mines, which would net \$5 to \$10 per ton at a modern smelter at Zimapan if freight was \$5 per ton. There is a probable profit of \$70,000 in the old Purisima slag dump at Zimapan. La Sirena lead-antimony deposit is an unusual one, and should be developed. In summarizing the Company's resources, Mr. Lindgren estimates a net return of \$120,000 from all the properties. Only high-grade ores can be shipped at present, and a 500-ton smelter may be profitable. Considerable capital is necessary for development, mining, and building a mill and smelter.

NUEVA LEON

The Monterey smelter of the American Smelting & Refining Co. was blown-in on October 1 after a shut-down of several months due to the revolution. Over 1000 employees have been given work.

SONORA

The arrival of General Carranza in Cananea was the occasion of a three days' *festa*, and it was only by heroic methods that the smelter was kept going. The mines were completely closed, and Cananea went on record as being a Constitutionalist stronghold. The three-day celebration in honor of General Carranza proved to be almost as serious a handicap to the Cananea Consolidated Copper Co. as was the battle in Cananea last spring which lasted for three days, during which time Mr. Cole, the superintendent, experienced many difficulties in keeping the smelter going. Since the new management has come into power, there has been a marked reduction in the number of Americans employed by the Company, the number being reduced from 600 to 120. Evidences of well planned economy are to be seen in every department. The Democrata Mining Co. is continuing operations under Gene Hoffman as superintendent, as is also the Moctezuma-Arizpe Development Co. The Calumet & Sonora Mining Co. is deepening the shaft, which is the only work that is being done at present.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HEINRICH RIES was in New York recently.

C. W. PURINGTON has returned to London from the Lena district.

CHARLES JANIN has been traveling in Spain and has gone to Italy.

R. T. MISHLER has been appointed superintendent for the El Tigre Mining Company.

N. O. LAWTON has resigned as superintendent for the Miami company and is returning to Michigan.

SIMON GUGGENHEIM has been elected chairman of the board of directors of the American Smelting & Refining Company.

W. D. MURRAY has been appointed general manager for the Corrigan McKinney Mining Co., at Terrazas, Chihuahua, Mexico.

S. S. SORENSSEN has moved his office from New York and is now general manager for the Braden Copper Co. at Rancagua, Chile.

L. B. SMITH, of Pittsburgh, has started on a several months' trip to the West Indies for the purpose of examining supposed oil properties.

GEORGE E. FARISH has left Nelson, British Columbia, and will stop in San Francisco on professional business, until November 1, before returning to New York.

STANLEY A. EASTON and J. F. MCCARTHY are members of the commission appointed by the Governor of Idaho to draft a workmen's compensation act for that state.

THE Associated Geological Engineers of Pittsburgh, Pennsylvania, is engaged in examination of oil properties in Vera Cruz, Mexico, the field work being in charge of L. G. HUNTLEY.

J. W. MALCOLMSON was in New York to attend the meeting of the nominating committee of the American Institute of Mining Engineers and has been in Philadelphia during the week.

E. J. CARLYLE has returned from professional work in the Argentine and is spending a holiday in the United States. He recently passed through New York on his way to Montana.

E. G. BANKS, for over twenty years metallurgist with the Waihi Gold Mining Co., New Zealand, has been appointed superintendent of the property in place of H. P. BARRY, who has resigned after many years in that position.

The United States Civil Service Commission, Washington, D. C., announces open competitive examinations for the following positions with the Bureau of Mines: electrometallurgists, at salary from \$1800 to \$3000 per annum; chief metallurgist, \$4000 to \$4800; metallurgist for work with smelter fume, \$2700 to \$3600; metallurgist for work in low-grade ores, \$3000 to \$4000; assistant metallurgist, \$2000 to \$3000; metallurgical engineer for work in iron blast-furnace operations, \$2500 to \$4000; metallurgical engineer for work in iron and steel, \$3000 to \$4000; and assistant petroleum chemist, \$1800 to \$2160 per annum.

Obituary

ALFONSO A. TREGIDGO will long be remembered as one of the most popular and able presidents of the California Miners' Association, with which organization he was connected from the time of its founding. Among the first of his undertakings was the organization of the Nevada County Power Co., of which he was the superintendent. Mr. Tregidgo had charge of the construction of the power-plant and the six-mile flume leading from the dam to the power-house, and after the completion of this work superintended the operation of the Grass Valley division of the Company. When the Alaska rush occurred, he sold his interest in this Company and went to Alaska, from which country he returned to take up his old work as superintendent of the St. John Quicksilver mines, which position he held at the time of his death.

Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

EASTERN METAL MARKETS.

(By wire from New York.)

New York, October 23.—The copper market is firmer and a slight upward movement is to be noted in the stocks. The fortnightly statistics on the foreign stock of copper show that the supply in England and France on October 16 amounted to 21,964 tons which is a decrease of 589 tons during the first two weeks of the present month. The visible supply of copper at Rotterdam, Hamburg, and Bremen on October 15 show a decrease in the stocks of 453 tons since October 1. The European demands at the present are good. The lead and spelter markets are quiet. Copper closed strong with spot at 16.75, electrolytic 15.87, casting 16.75. The tin market is steady with spot, and October at \$40.25 to \$40.50. Antimony is dull with Cookson's quotation at \$7.60.

SILVER

The weak spot during the week has been China, whence selling orders have been sent with some freedom, according to Samuel Montagu & Co. on October 2. In a normal all-round market, probably the effect of these sales would have been felt less, but at the present time, with often only one buyer in the field, any tendency on the part of one of the great consuming countries to contribute supplies rendered it an easy matter for the buyer to let prices fall. So long as China sells, or threatens to sell, prices are likely to sag, but when an exchange level is reached, at which operations cease to be advisable, China may begin to cover and thus afford the market the stimulus of competition. The latter rains in India have proved favorable, so that, within the next few weeks, the Indian Government will be in a position to estimate the future needs of its currency with some degree of confidence. A review of the Indian silver position shows that this country alone, exclusive of those parts of India not administered by the Crown, consumed during the past decade an annual average of 71,909,900 oz., approximately one-third of the present annual output of the world. This absorption took place side by side with greatly increased gold imports.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

The copper market last week achieved the feat of strengthening considerably without any great volume of business having been transacted. On October 11 there was a decline in the price of standard warrants, and on the 14th G. M. B.

copper closed in London at £70 10s. for both spot and futures, showing a marked decline. The market here was flat, but the rebound of £1 per ton in London, reported by cable the following day, gave the market a stronger tone. The figure asked by the chief sellers here and abroad was 16½c., but Aron Hirsch & Sohn were quoting the equivalent of 16c. in London, while sales in small lots by 'second hands' were made as low as 15½c. here during the week. On October 16 and 17 European buyers bld 16½c. for 30 days and placed good-sized orders at that figure. The domestic buyers still hold off, and spot copper can be had for 16½c. Domestic buyers usually follow the European lead, so that larger sales were expected the week following. Exports of copper from New York, October 1 to 16, were 15,521 tons, as compared to 13,740 tons for the same period last year. The European statement showed a decline of 1042 tons in the visible supply during the first two weeks of October. On the 16th the report came that the miners at Rio Tinto have struck, and a further decrease in the output should strengthen the situation of the metal.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending	Oct. 8.....	39.50

ASBESTOS PRODUCTION

A comparison of the figures of production of asbestos in the United States for 1911 and 1912 shows that the output for 1912 was considerably less than that of the previous year, yet notwithstanding this fact the production for 1912 was the largest in the history of the industry, except that of 1911. The production in 1912 was 4403 short tons, valued at \$87,959, against 7,604 short tons, valued at \$119,935, in 1911, according to a U. S. Geological Survey report.

The San Francisco Stock and Bond Exchange held its annual meeting on October 14 and re-elected G. I. Ives, president; Milton A. Bremer, vice-president; Frank C. Shaughnessy, chairman; L. Strassburger, vice-chairman; Harry Schwartz, secretary; and the Bank of Daniel Meyer, treasurer. All of these are the present incumbents of their respective offices. The report of the exchange of the business transacted during the year ended September 19 shows bonds of a total market value of \$13,503,242 and stocks of a market value of \$7,335,215.50. The total is \$20,838,458. The stocks dealt in included water stocks to the market value of \$1,554,207; gas and electric, \$439,916; insurance, \$129,974; commercial bank, \$382,773; savings bank, \$19,686; street railways, \$46,568; powder, \$97,360; sugar, \$886,090; oil, \$2,607,718; and miscellaneous, \$1,170,919.

Company Reports

OROVILLE DREDGING COMPANY, LTD.

OROVILLE DREDGING, LTD.

This company operates dredges at Oroville, Butte county, California, and also in Colombia, Central America. The reports and accounts of the English company cover the period from October 1, 1911, to June 30, 1913; while in connection with the American company, Oroville Dredging, Ltd., there is a report by Theodore J. Hoover dated May 16, 1913; a report by W. P. Hammon dated July 15, 1913; and accounts to July 31, 1912; and January 31, 1913. The annual meeting of the Company was held in London on September 30, 1913.

The directors' report states that since the last report 10,773 shares of the English company have been issued in exchange for an equal number of the American company's shares, making a total to date of 570,514 shares. No dividends having been paid by the latter Company, the English company's income was derived from agency and transfer fees only. The operating profit of the American company for the year to July 31, 1912, was \$261,624, and the net balance, after charging general expenses, etc., was \$255,509. Of this, \$60,808 was written off for dismantling dredges, leaving \$194,701, and adding the balance from the previous year, the surplus July 31, 1912, was \$299,603. The American company's accounts for the half-year to January 31, 1913, shows a further surplus of \$101,894, making a total of \$401,497.

During the 18 months to January 31, 1913, the dredges at Oroville handled 7,062,528 cu. yd. of gravel yielding gold worth \$726,302, equal to 10.28c. per cu. yd., against \$456,789 and 10.24c., respectively, in the previous twelve months, the relative profits being 5.21 and 4.42c. per cubic yard. The final and total net profit which the Company may expect to derive from its Oroville property during the six years of its life, will be about \$480,000. The estimated net return to Oroville Dredging, Ltd., from the Pato business, Colombia, is £350,000, but does not include the probable returns from California hill on the 'ring of gravel around the periphery of the 310-acre area,' or possibilities from other parts of the 20,000-acre concession. Drilling and sampling California hill is to be done. The cash outlay for the Pato equipment is \$986,278. Up to August 9, 594,570 cu. yd. of gravel had been dredged, yielding \$115,077, equal to 19.35c. per yard. Regarding the financial condition of the Company, on August 31, the net liability was \$178,000, not including a loan and interest of \$149,000 due the Consolidated Gold Fields of South Africa, Ltd. Dividends may be expected early in the summer of 1914.

The report of Theodore J. Hoover to the English company, Oroville Dredging Company, Ltd., deals with the condition of the dredges at Oroville, California. Exploration No. 1 dredge was dismantled as being completely out of repair; California No. 2 has reached the limit of its existence, and has practically dredged all its available ground; Exploration No. 2 is 10 years old and has nearly finished its work; Exploration No. 3 has been kept in good order and will operate for five or six years; and Boston No. 4 should have a similar life. The position now is, that at the end of 1913 there will be only two dredges working. There is no prospective value in the Oroville operations. The report of W. P. Hammon shows that during the 18 months under review, 143.23 acres was dredged at Oroville, leaving 386 acres to be treated. At the Pato property there are 40 white men and 350 natives employed, and 6% are treated daily for ailments incident to the tropical climate. A heavy investment has been made in this property.

TRANSVAAL GOLD MINING ESTATES, LTD.

The Company now owns freehold farms with an area of 172,209 acres; mineral rights over 18,779 acres; concessions granted by the Government in respect of various farms, and 891 mining claims; also water rights, etc. The capital is £640,000 in 640,000 shares of £1 each; 604,225 of the shares are issued and fully paid. Debentures totaling

£105,564 have been issued. The report for the year ended March 31, 1913, gives detailed accounts from the Central, Elandsdrift, and Vaalhoek mines. The tonnage mined at the Central Mines amounted to 148,834 tons, at a cost of 7s.8.07d. per ton mined. At the 60-stamp mill 148,600 tons of ore was crushed, at a cost of 1s.4.27d. per ton milled. The total value of the gold recovered from the tube-mills was £205,940, at a value of 27s.8.610d. per ton milled. In the cyanide operations 146,050 tons was treated, and 47,902 oz. fine gold recovered, valued at £200,814, a value of 27s.5.99d. per ton treated, at a cost of 3s.3.79d. per ton milled. Also 7342 tons of accumulated slime was treated and 2572 oz. of fine gold recovered at a cost of 5s.4.98d. per ton treated. The total revenue was £407,180, and the working profit was £245,296, or 33s.0.17d. per ton milled. The ore reserves were estimated to be 385,547 stopping tons, valued at 14.23 dwt. per ton. At the Elandsdrift mine 7872 tons of ore was transported to the mill, at a cost of 1s.0.65d. per ton milled. The yield per ton was 18.68 dwt., a total value of £30,720, at a cost of 5s.1.38d. per ton milled. The total value of the 7908 tons treated in the cyaniding operations was £5836 1s.11d., at a cost of 4s.1.51d. per ton milled. The total working expenses were 31s.7.16d. per ton milled. The revenue was £36,556, and the year's profit was £24,260, or 62s.2.07d. per ton milled. The ore reserves were 30,210 tons. At the Vaalhoek mine the tonnage mined was 15,607 tons. At the mill 16,355 tons was crushed, at a cost of 2s.4.59d. per ton. In the cyaniding operations 16,243 tons was treated, at a cost of 8s.6.10d. per ton. The total revenue was £25,860 and the profit was £8395, or 10s.3.19d. per ton. A calculation of the ore reserves showed 40,892 tons of an average value of 10.36 dwt. The net profit of the Company for the year was £277,415. Dividends to the amount of £226,584 were paid.

GREAT FINGALL CONSOLIDATED, LIMITED.

This Company was registered in 1899 to acquire the holdings of the Great Fingall Reefs, Ltd., and the Consolidated Murchison Gold Mines, Ltd., consisting of property situated at Day Dawn, near Cue, Western Australia. The capital is £125,000, in 250,000 shares of 10s. each; all the shares are issued and fully paid. The report for 1912 shows that 67,177 tons of mine ore was treated at the Company's mill during the year, the total working expenses being 23s. 10d. per ton. In addition, 4426 tons of customs ore and 467 tons of purchased concentrate were treated. The total extraction of gold was 92.8% of the assay value. The gold recovered from the mine ore amounted to £115,783; that from the customs ore amounted to £16,262. The total income was £133,910, the surplus being £16,250. It was estimated that on December 31, 1912, there was, above the No. 14 level, 21,151 tons of ore of an average value of £1 6s. 5d. per ton, and 50,308 tons below that level, of an average value of £2 per ton. This latter will be available for the mill on completion of the new winze.

PRESTEA BLOCK A, LTD.

The Company was registered in 1903 to acquire from the Prestea Mines, Ltd., and the Appantoo Mines, Ltd., portions of the Essarman and Intermediate concessions in the Prestea district, near the Ancobra river, Gold Coast colony. The authorized capital is £1,150,000 in 1,150,000 shares of £1 each; 1,049,876 shares are issued and fully paid. There is a loan from the Central Mining & Investment Corporation, Ltd., and the Fanti Consolidated Mines, Ltd., of £150,000. The report for the year ended December 31, 1912, gives the total milled as 172,319 tons of ore. The gold recovered realized £296,382, or 34s.4.79d. per ton. The expenses were 28s.10.9d. per ton.

The ore reserves were estimated at 835,014 tons with a value of 44.4s. per ton. The operations for the year resulted in a profit, before charging depreciation of £38,345 1s., of which £14,254 has been appropriated to writing off the debit to that amount in the profit and loss account at the rate of 31s. to December 1911, and the balance, £24,091, has been allotted to depreciation of plant, machinery, and buildings.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE FLOTATION PLANT at the Wallaroo & Moonta mines, South Australia, is recovering 95% of the copper content of the crude ore.

A TOP TUMBLER for a dredge in the Philippine Islands, being manufactured in Victoria, Australia, has five sides instead of the usual four-side design. It weighs about 7 tons, and similar tumblers have given good results.

PECK CENTRIFUGAL MACHINES are in use for concentrating slime at Anaconda. Experiments are being conducted with two types, one discharging from the top and the other from the bottom. Each machine includes two concentric vertical cylinders driven at different speeds. The discharge is intermittent and effected by decreasing the speed of one cylinder.

THE USE of asbestos-protected metal for the roofing and siding of buildings in the construction of steel plants was recently given great impetus by an unfortunate accident in the gas-producer building of one of the largest steel plants in the East. Several men were struck by tiles loosened from the purlins by an explosion. Several men were killed and others seriously injured in this manner. Asbestos-protected metal has already been standardized as a roofing and siding for various classes of buildings in steel mills, sixteen steel companies being continuous purchasers. The American Steel & Wire Co. was the first of this number to purchase asbestos-protected metal, having commenced its use some five years ago.

COMPARING the results obtainable with a jet and a surface condenser, J. H. Ledebor, in the *Proceedings* of the Australasian Institute of Mining Engineers, summarizes as follows: (1) The possible vacuum depends in every case on the hot-well temperature. The lower this is the higher the possible vacuum. (2) In a mixing condenser this highest possible vacuum can be reached without difficulty, and it can be maintained in practice with little trouble. (3) The hot-well temperature in a surface condenser will always be higher than in a mixing condenser, supposing there is the same steam consumption and same cooling water. This difference may be from 5 to 15° in ordinary practice. (4) As a result, with a surface condenser (without hot-well cooler) under the same circumstances the vacuum obtainable in a mixing condenser cannot be reached. (5) If the surface condenser is fitted with separate cooler, the hot-well temperature may be reduced and give better results. (6) In the last-mentioned case feed-water of a higher temperature can be had than in the hot-well by pumping the condensed water with a special pump, draining it off before it reaches the hot-well, and pumping the air with a separate dry-air pump.

In Agricola's 'De Re Metallica' is the following on milling: Some people build a machine which at one and the same time can crush, grind, cleanse, and wash the gold ore, and mix the gold with quicksilver. This machine has one water-wheel, which is turned by a stream striking its buckets; the main axle on one side of the water-wheel has long cams, which raise the stamps that crush the dry ore. Then the crushed ore is thrown into the hopper of the upper millstone, and gradually falling through the opening, is ground to powder. The lower millstone is square, but has a round depression in which the round, upper millstone turns, and it has an outlet from which the powder falls into the first tub. A vertical iron axle is dovetailed into a crosspiece, which is in turn fixed into the upper millstone; the upper pinion of this axle is held in a bearing fixed in a beam; the drum of the vertical axle is made of rundles, and is turned by a toothed drum on the main axle, and thus turns the millstone. The powder falls continually into the first tub, together with

water, and from there runs into a second tub which is set lower down, and out of the second into a third, which is the lowest; from the third, it generally flows into a small trough hewn out of a tree trunk. Quicksilver is placed in each tub, across which is fixed a small plank, and through a hole in the middle of each plank there passes a small upright axle, which is enlarged above the plank to prevent it from dropping into the tub lower than it should. At the lower end of the axle three sets of paddles intersect * * * and the whole is turned by a toothed drum. * * * Thus the paddles, of which there are three sets in each tub, turn round, and agitating the powder, thoroughly mix it with water and separate the minute particles of gold from it, and these are attracted by the quicksilver and purified. The water carries away the waste. The quicksilver is poured into a bag made of leather or cloth woven from cotton, and when this bag is squeezed the quicksilver drips through it into a jar underneath. The pure gold remains in the bag. Some people substitute three broad sluices for the tubs.

EMPLOYEES of large mining companies should have every facility given them to live in comfortable homes, especially if the properties are in outlying districts. The Granby Consolidated company, which is developing a large copper mine and erecting a smelter at Anyox, British Columbia, is evidently determined to treat its men well, and is erecting cottages for them; the accompanying half-tone shows the type of houses being built. The rental is

EMPLOYEES' COTTAGES AT ANYOX, BRITISH COLUMBIA.

\$3 per month per room, with electric light, bath in every house, even with two rooms. At the mine there are fourteen 4-room and four 5-room cottages completed. The old bunkhouse has been renovated and will house 35 men. A two-story bunkhouse, 30 by 120 ft., with basement containing lockers, showers, and tubs, is ready for 110 men. The mess has a capacity of 250 men, with cold-storage plant. All buildings are connected with water and sewer systems sufficient for present and future needs.

THE BLACK GOLD obtained in parting in gold assays is regarded by many and mentioned in some books as an allotropic form, on account of its color and slight increase in density. The color of parted gold depends on the proportion of gold to silver in bullion, according to E. C. Woodward, of Colorado Springs. In the bullion assay, where the proportion is $2\frac{1}{2}$ to 1, the gold is left as a solid yellow mass. As the proportion of silver increases, the gold is left more finely divided, in a black spongy mass, or even scattered in fine black particles. If this black spongy mass is boiled in strong acid, it shrinks, and often shows a distinctly yellow color. A gentle heat or a moderate pressure will condense the black sponge and change its color to yellow. In a strong light, a yellow tinge can generally be seen, and the blackest gold he has prepared, dried in the sun, or even undried, showed an unmistakable gold color under the microscope. Victor Parchl, in 'Chemistry of Colloids,' states that the density of bodies increases with progressive division. Rose gives the specific gravity of rolled gold as 19.33; parted gold, 20.30; and precipitated gold as finest powder by ferrous sulphate as 20.72. From these facts it seems certain that black gold is simply gold in a state of fine division.

Motor Trucks

The advent of the motor truck into the mining field has met with such success that it has come to be looked upon as a necessity in the operation of some properties. In localities distant from the railway and where muleback transportation or wagon haulage was the only means of handling supplies and mine products, the motor truck has found a place and proved itself a most efficient and convenient means. The advantages of the motor truck over the old methods are numerous, and when reduced to the ton-mile basis, with everything considered, have shown a decided saving over the old methods. In numerous instances mining companies have gone to great expense in the construction of roads over which motor trucks could be operated, and even with this great outlay of capital in road construction for no other purpose than to replace the mule or wagon, experience has shown that the substitution of the modern for the ancient means of transportation has not only greatly expedited the handling of supplies and products, but has materially decreased the freighting charges.

Among the companies manufacturing motor trucks, the Moreland Motor Truck Co., of Los Angeles, California, has recently issued a bulletin descriptive of the trucks being

MORELAND TRUCK.

manufactured by this Company. The catalogue is both attractive and instructive, and presents the merits of the trucks in a novel manner by means of blueprint reproductions. These plates show the construction in detail and will appeal to the mechanic who is more interested in the construction of the chassis than the color of paint on the body. The Moreland trucks are designed to operate with California No. 1 distillate, a product peculiar to the Pacific Coast, and which, it is claimed, assures a saving in fuel cost of at least 50% over that of gasoline-operated trucks. It has been the aim of the Company in the building of motor trucks not to see how cheap they can be made, but to construct trucks that will handle the greatest tonnage in the most economical way. Quality has been the first consideration, and it has been the purpose to put the best material available into their making. While the trucks are designed to operate on distillate, any low-grade hydro-carbon or gasoline can be successfully used. The trucks are guaranteed to operate with California No. 1 engine distillate at a saving in fuel cost of 50 to 60% over any gasoline truck. It is also claimed that the distillate gives an increase of approximately 20% in power. From a small beginning, this Company has grown to one of importance in the motor truck field, and its products have come to be recognized as one of the standards of motor truck construction.

The production of zinc and zinc-lead ores in 1912 increased about 1,340,000 tons over the output of 1911. A considerable portion of the zinc and zinc-lead ore is used in the manufacture of pigments.

The total mineral production of Australia to date is worth approximately \$3,840,000,000, of which gold was responsible for 70%, coal 9%, silver and lead 8.5%, copper 7.5%, and tin 4 per cent.

Recent Publications

ANNUAL REPORT OF THE DEPARTMENT OF MINES FOR AUSTRALIA FOR 1912. Presented by H. S. King, is compiled from reports from officers controlling the various sub-departments throughout the state of Western Australia. P. 265. Ill., maps, charts. Perth, 1913. Although somewhat belated, these annual reports are of great interest, and under the various chapters are given a summary of the past year's work, details of minerals mined, area of mining leases, men employed, accidents, state aid to mining, reports from district officials, legislation, inspection of machinery, school of mines, report of the state mining engineer, report on state mills, geological survey report, reports of the machinery inspector and inspector of explosives, and 115 pages of statistical matter. The mineral output of the state amounted to £5,760,207, being £345,646 less than 1911. Gold accounted for a decrease of £374,690, while there were increases of £24,703 in coal, £15,358 in tin, and £7563 in lead ore. Gold accounts for 94.58% of the total mineral output, the total to the end of 1912 being £109,298,872, and total mineral output of £113,326,510.

Mining companies paid £814,256 in dividends. During the year all mines treated 2,688,868 tons of ore, the average value being 39.64 shillings per ton. The area held under mining lease for all minerals was 56,602 acres; 14,961 men were employed; copper exports were £60,537; six coal mines produced 295,079 tons, and silver produced was 138,039 oz. During the current year, 1913, the gold yield of the state took an upward turn, after nine years' decrease. From time to time, extracts will be made from this report and published in these columns.

THE presidential election in Mexico, or, to be more exact, the straw vote, does not seem to have cast any oil on the troubled political waters of our southern neighbor. Sr. Huerta still holds the tiller and the red flag of the *revolucionarios* is as much in evidence as before this latest political farce was enacted.

STANDARDIZATION of metallurgical and mining terms has recently received the approval of the council of the Chemical, Metallurgical, and Mining Society of South Africa. It is gratifying to know that this society has black listed such terms as 'mullock,' 'lasher,' 'kokopan,' and others, and gone on record for the differentiation of the spurious from the standard in the good cause of sound diction. There is still hope that the English speaking miners will some day speak one language, and not, as were the workers on the Tower of Babel, be impeded by words and idioms both spurious and confusing.

THE Russian Government, through the Ministry of Trade and Industry, is preparing a new law for regulation of gold mining, under which a progressive rental will be required for all claims granted for the exploitation of gold. According to the duration of the concession a minimum production will be required of the gold placers. A regulation will also be included whereby, if the concession is not exploited within a given time from the date upon which it was granted, the claim will revert to the government. It is hoped that this measure will be the means of doing away with the speculation in gold placers.

THE 'high plane' strike of the coal miners of the state of Colorado appears to have degenerated into a condition of mob violence and bloodshed. Martial law has been declared in the disturbed districts and the stand which has been taken by the Governor toward the suppression of lawlessness does not augur well for those strikers who would carry their cause by force of arms. By what process of reasoning those responsible for present conditions hope, by the present course, to gain the concessions demanded, is beyond our ken, and we have yet to record a victory for organized labor where the psychology of the mob came into play.

TIME indeed brings changes, often rapid ones. The memory of gloomy prophecies of a rubber famine is still green, yet in a recent issue of the London *Financial Times* a correspondent strongly urges the formation of a Rubber Association to promote the use of rubber and find new uses, on the

ground that at the present price to which that commodity has declined, few of the rubber producing plantations can make even a reasonable profit. All of which inspires many reflections, above all, that the output of any commodity increases rapidly under the stimulus of higher prices. One result of the change is to seriously disturb Brazil's finances, since a large part of the revenue of several Brazilian states was derived from an export tax on rubber. With high prices and a practical monopoly of the field, this did very well, but now there seems to be serious danger ahead for the rubber growers along the Amazon.

RAILROAD construction in Nicaragua is about to receive an impetus through the \$3,000,000 loan which was recently made in New York by the government of that country. The proposed extension is from Rama to Lake Nicaragua, where it will connect with the railroad on the west coast. The proposed road will be of direct benefit to the mining industry by affording better transportation facilities. Mining progress in Nicaragua, like in all of the other Latin-American countries, has been impeded by lack of railways, and any new construction will be welcomed by operators. It is understood that the Nicaraguan government hopes to place another and larger loan in this country soon for financing other lines which will make additional territory available for exploitation.

INVESTIGATION of the strike, conducted by a committee of the Copper Country Commercial Club of Michigan, has resulted in such fair and equitable conclusions that it is hoped that their publication may help toward an amicable understanding. The committee has come to the conclusion that the mine managers will not recognize the Western Federation of Miners; that no minimum wage applicable to all mines in the district can be established; and that the one-man drill has come to stay. It has further concluded that the question of establishing an eight-hour working day ought to receive the serious consideration of both men and operators, and also that some attempt ought to be made to provide an adequate method by which the employee can have free access to the management for the purpose of presenting grievances without fear of discrimination or discharge. At a meeting subsequently held, at which there were present representatives of each of the companies mentioned in the report, it was agreed that they were willing to act upon the recommendations that were presented and that each manager would establish and have in operation an eight-hour working day for underground employees on or before January 1, 1914. It was also agreed that arrangements shall be made whereby the matter of grievances will be adjusted and every complaint investigated with all possible speed. In the current edition we publish that part of the report pertaining to the one-man drill from which the thoroughness and fairness of the committee may be judged. It is to be hoped that the publication of this report will clear the atmosphere and correct false statements that have been circulated regarding the actual conditions in the Lake Superior district.

NO RECENT occurrence is so profoundly significant of the new spirit of the time as the legacy left by Benjamin Altman, who died in New York but a few days ago. Starting from humble beginnings he built up during his lifetime a large department store business, from the profits of which he accumulated an art collection valued at \$15,000,000. On his death, though possessed of numerous relatives and though a member of a race popularly supposed to be peculiarly clannish and grasping, he left his art collection to the people of the city of New York and his huge and profitable business to the Altman Foundation, which is directed to administer it for the good of its employees and of such charities as the Foundation may think worthy. No member of the Foundation is to receive compensation for his services and the corporation thus becomes essentially a public institution. During his lifetime Benjamin Altman was the leader in the movement for providing better working conditions and better compensation for employees in department stores. His efforts were deprecated by sincere men who honestly believed that such methods were incompatible with the profitable operation of the business, yet his profits continued to increase and he lived to see the day when such methods were acknowledged as good business, tending to higher efficiency. To those whose faces are still toward the past his life is commended for an example. Everywhere there are sincere men who see in workmen's compensation, safety laws, and other forms of labor legislation only undue aggressions against the vested rights of capital. To all such we commend the idea of the evolution of industrial and social liberty.

SAFETY can never be absolute in mining. There will always be some loss of life in this as in other industries, but it may be possible to greatly reduce the number and severity of accidents. Many are discouraged over the fact that some of the worst accidents have happened in some of our best equipped mines, as at Stag Cañon. In this, however, we think the correct attitude is that taken elsewhere by Mr. J. A. Holmes, who reasons that these disasters should but bring us to realize that our work has barely begun. The brave helmet men who were crushed under a roof-fall while exploring the mine in advance of regular workers, were on the skirmish line in more ways than one. They will not have died in vain if lessons from this great disaster lead to greater safety in mines yet to be worked. Complete and immediate success can no more be fairly anticipated in this than in other lines of endeavor, but steady persistent work will minimize the loss of life. American mine operators have been quick to realize the value of the newer mine-rescue apparatus and they have been generous in their purchases: it is a serious question whether the men have been equally willing to submit to the discipline, to do their part in the day by day vigilance that alone will prevent loss of life. None are readier or bolder to attempt saving a fellow worker when in actual peril, but to prevent his being imperiled is another matter. The cause of the Stag Cañon disaster is yet unknown, and for the present one can but urge upon both men and operators the necessity for constant watchful-

ness. The sympathy of the whole mining world goes out to the men and their families and to Dr. James Douglas and his capable hard working staff. There are few properties at which one could be equally sure that everything possible had been done to forestall and prevent disaster.

Electric Smelting of Copper Ores

With the growing importance and availability of electric power, especially hydro-electric power, and the continual improvements in the design and construction of electrometallurgical apparatus, the smelting of copper, and more especially zinc, ores by electrically generated heat is a possibility which may well engage the attention of those who are concerned with metallurgical progress, as well as with the payment of present dividends. The authors of the paper presented in the current issue on the application of the electric furnace to Western metallurgy have been engaged by the Bureau of Mines to make a detailed study of this subject, and the results of their work will be more fully set forth later in publications of the Bureau. As is both natural and right, Messrs. Lyon and Keeney have adopted an optimistic viewpoint, and in the interest of obtaining a well rounded view of the situation, it will be well to call attention to the factors unfavorable to the immediate development of an industry in which the heat for smelting is generated from electrical energy.

In the computation of the cost of electric power for smelting, those who take an optimistic view commonly reckon that electricity may be obtained at a cost of 0.15 cent per kilowatt-hour, or about \$10 per horsepower-year. As compared to the extraordinarily low cost for the production of electric power which has been attained in some parts of Europe, this may seem a liberal allowance to the advocates of electric smelting. As a matter of concrete fact, however, the cost of hydro-electric power, in the mountain districts of California, is \$50 per horsepower-year to consumers of moderate amounts, and even consumers who will take a steady load of 10,000 horsepower have to pay at the rate of at least \$16 per horsepower-year. In his interesting paper on hydro-electric development in Montana, Mr. Max Heibgen makes the statement that the coal necessary to develop by steam power the 49,500 kilowatts now produced by the Montana Power Company and its subsidiaries would cost \$45 per horsepower-year. It is unfortunately probable that the use of electric energy for smelting will have to be developed under unfavorable conditions, rather than those which are most favorable, and it is only fair to state that there is every evidence that electric smelting will have to be upon the basis of a power cost which is nearer one cent per kilowatt-hour than the figure usually cited. On the basis of a theoretical computation in which it is assumed that the thermal efficiency of a coke-fired blast-furnace is 50 per cent and the efficiency of the electric furnace is 70 per cent, it is deduced that coke and electric energy are on a par at \$7 per ton for coke and \$10 per horsepower-year for electric energy. With electric power at the more probable

cost of \$30, this corresponds to \$21 per ton for coke, and even this figure neglects the cost of electrodes, which is estimated at 30 cents per ton of charge smelted. The cautious manager hopes for the best conditions and prepares for the worst, and upon this basis it is difficult to believe that, except under unusually favorable conditions, electric smelting can be done at a cost which will permit of its wide use, for the present at least.

Other conditions than those of cost are of importance in the regular conduct of smelting work, however, and it may be pointed out that the barring down of crusts is a normal action in copper blast-furnace smelting as usually practised. This is almost incompatible with the use of refractory linings in the construction of a smelting furnace. The assumption that the thermal efficiency of an electrically heated furnace will be 20 per cent greater than that of the ordinary copper blast-furnace will require experimental demonstration before it can gain general acceptance. It must not be overlooked that in experiments which have been conducted, the volatilization loss was 1 per cent of the copper present when smelting native copper concentrate containing about 30 per cent copper. In the other experiments, the volatilization loss is not given beyond the statement that it is low. It must be remembered that our knowledge of slag composition and slag losses is based upon practice in which the average temperature within the furnace is lower than is likely to be the case in electric smelting, where the heat generated is concentrated in a comparatively narrow zone between the electrodes, rather than distributed throughout the zone of combustion, as in the blast-furnace. What difference this will make in practical operation can only be determined by much experiment, in which the Bureau of Mines is properly taking the initiative.

Just as smelting in the blast-furnace, utilizing only the heat of the sulphur in the charge, is theoretically possible, but in practice the use of coke to increase the tonnage handled per day is an economic advantage, so the use of electric energy will be conditioned upon the profit obtainable from its use, and profits can only be determined by introducing all working conditions in experiments upon a working scale. Considerations of space prevent fuller discussion here, but we will be glad to accord space in the 'Discussion' column for the views of our readers.

It is unquestionable that if the early experiments which painfully led up to the present converter practice and pyritic smelting had been made by an organization like the Bureau of Mines rather than under the irrelevant difficulties at Toston, Butte, and elsewhere in Montana and Colorado, progress would have been more rapid than was actually the case. Promising experiments have often been dropped because some structural feature unexpectedly failed and the management was unwilling to incur the expense of reconstruction. We congratulate the Bureau upon being both able and willing to undertake the work necessary for the development of an exact knowledge of the possibilities of electric smelting.

The Rand Banket—Part III Continued

By C. B. HORWOOD

Emmons, in discussing metasomatism, states that the interchange is not necessarily molecule by molecule in such manner as to preserve the original form, structure or volume of the replaced substance.¹¹²

Van Hise¹¹³ assumes a change in volume and maintains that "the volume of the original compound is to the volume of the compound produced, directly as their molecular weights and indirectly as their specific gravities." The latter part of this statement means that the weight of the compound produced is the same as that of the material that has undergone dissolution. If this be so, the process is not a simple molecular one as between molecule and molecule; if molecular at all, the exchange implies the principle of multiple proportions. In the case of the Rand conglomerate, the microscope shows clearly that quartz¹¹⁴ has been replaced by iron pyrite and gives no indication of any mechanical process, or of any intermediate stage, either of open space or due to a two-stage chemical process. The molecular weights of these two substances are 60.4 and 120 and their specific gravities are approximately 2.7 and 5.0 respectively. Thus, according to the first portion of Van Hise's statement, the volume of the original compound is to the volume of the compound produced as 60.4 is to 120. We know that this was not so, for if it had been, the spaces originally taken up by the pyrite 'pebbles' would have been double that previously occupied by the replaced material; and whatever subsequent contraction had taken place, the microscope would have revealed some signs of the enormous pressure originally exerted by the new mineral against the host mineral. It has not done so.¹¹⁵

Change in Size of Pebbles

According to the second part of his statement, these volumes are as, say, 5 to 2.7. This would mean that the original volumes of the pyrite 'pebbles,' not allowing for any subsequent contraction, were only about half the volumes of the material replaced. This is evidently not so, from the fact that the fibrous silica, which is of later growth than the pebbles, only exists in comparatively small quantities round portions of some of the pebbles, and the microscope reveals no indication of any substance, or falling in, of

the matrix round any of the pebbles. Moreover, in this example the two parts of his formula contradict one another; as according to the first part of it the volume occupied by the pyrite should be greater than that previously occupied by the replaced substance; and the second portion of his supposition requires that the pyrite should fill less space than was filled by the material replaced. Thus no great importance need be attached to his statement as a whole.

Sullivan,¹¹⁶ in summarizing the conclusions to be derived from his own experiments in attempting to apply chemical methods to the investigation of geological processes, and especially that of the secondary deposition of ores, was rather more cautious than Van Hise. Though he was not discussing exactly the same subject, it relates sufficiently to it, however, to be worthy of reference here. As before-mentioned, he states: "The natural silicates precipitate the metals from solutions of salts, while at the same time the bases of the silicates are dissolved in quantities, nearly equivalent to the precipitated metals." He adds: "Where exact equivalence is wanting, it is attributable either to solubility of the mineral in pure water or to the precipitation of basic salts." He evidently regarded equal volumes, before and after, as the general rule.

Metasomatic Changes

Posepny¹¹⁷ considered that metasomatic interchange took place without alteration of volume; for example, he stated that "after the expulsion, atom by atom, of the original material, the resulting deposit must be massive, showing no crustification."

Lindgren,¹¹⁸ in dealing with metasomatism, distinguishes between three kinds of reactions: those in open space; those in yielding material; and those in rigid rock, where the new mineral is forced to make room for itself by solution of the host mineral. In the latter he concludes that "the volume of the replacing mineral equals that of the mineral replaced." He maintains that the chemical equations written to express such replacements are of little value because they give relations by weight instead of volume, and that "such replacement proceeds independently of molecular weight, molecular volume, and specific gravity." Further, that it does not take place, molecule for molecule, nor by a given proportion between the molecules dissolved and precipitated. However, he thinks it is molecular, or at least sub-microscopic, inasmuch as there are constant chemical reactions taking place in the contact films of solutions; but that the process proceeds in one operation, solution and precipitation following so closely that no solution spaces are discernible under the microscope.

¹¹³'Metamorphism,' U. S. Geol. Surv. Mon., Vol. 47 (1904), p. 209.

¹¹⁴The portion replaced is often not all pure silica, but the small percentage of silicates it contains would not affect the argument.

¹¹⁵Increase of volume as a result of metasomatic interchange has never been recorded (see J. D. Irving, *loc. cit.*) Further, since, as shown later, the mineralizing solutions were introduced after the conglomerate had been subjected to the enormous pressures that tilted them into their present positions, and after the intrusions of the big longitudinal or strike dikes, it is difficult to imagine how the metamorphosed beds could have then been sufficiently yielding to have allowed such great expansion to have taken place.

¹¹⁶Sullivan, E. C., *loc. cit.*, p. 64.

¹¹⁷Posepny, F., *loc. cit.*, p. 16.

¹¹⁸*Loc. cit.*, pp. 525 and 534. For a lengthy and interesting discussion on replacement, see 'The Nature of Replacement,' by Waldemar Lindgren, *Econ. Geol.*, Vol. VII (1912), No. 6.

Volume v. Specific Gravity

Further investigation may show that the volumes do somewhat depend on the specific gravities of the two materials. Possibly the molecular volumes of the two substances also affect the question. The molecular volumes of quartz and pyrite are 22.8 and 24; there is so slight a difference between them that, judging from the particular occurrences under consideration, it might easily be that the volume of the pyrite is to that of the replaced material either inversely, or directly, as their molecular volumes. If so, the evidence indicates that the changes in volumes are inversely as their molecular volumes.

Thus the opinions of Emmons and Van Hise are that replacement is not necessarily by equal volumes. Sullivan thinks the change is by equal, or nearly equal, volume. Posepny was of the opinion that the change took place by equal volumes. Lindgren concludes that where it takes place in rigid rock it does so by equal volume.

The truth is, that this subject, which is not only deeply interesting but is one of great value in the study of many problems in economic geology, has not in the past been given the attention that its importance warrants. Few facts are available; and it should afford a good field for further research, which is much needed.

Classification of Pebbles

From the foregoing it is clear that the so-called 'pebbles' of the Rand banket are replacement products, which may for convenience be divided under the three following headings:

1. Those that have been formed by the replacement of the matrix of the banket.
2. Those that have been formed by replacement of the matrix and pebbles indiscriminately.
3. Those that have been formed by replacement of the pebbles of the banket.

Those falling under the first two headings may be termed metasomatic concretions; and those coming under the last heading may be termed metasomatic pseudomorphs.¹¹⁹

In all cases they have been formed by the process known as 'replacement' or 'metasomatism.' To the former class the term 'concretion' is applicable, inasmuch as they have been formed from within outward; the microscope shows that in the case of each such 'pebble,' growth has usually taken place from several independent centres rather than from a single one. The other term, 'metasomatic pseudomorph,' is used to distinguish such replacements from the better known and more usual type of pseudomorph, which latter has been formed by the independent growth of one substance in the likeness, or in the crystalline form or habit, of another; the likeness not

having in any way been, so to speak, forced upon it by any metasomatic process.

As regards the substance attacked, it has been shown that pebbles of quartz, quartzite, and hard cherty-looking slate or slaty-quartzite are replaced. Another substance commonly replaced is the matrix of the banket; this contains sericite and other matter containing alumina, so that where this has been replaced, both quartz and silicates of alumina have been replaced. The frequency with which partly replaced angular, indurated, slaty-quartzite pebbles occur as compared with all kinds of wholly replaced 'pebbles' or with other intermediate partly replaced forms, has already been mentioned and indicates that these pebbles are more readily replaced than pure quartz pebbles.¹²⁰ Also pyrite 'pebbles' that

¹²⁰The writer pointed this out elsewhere (see 'The Mode of Occurrence and Genesis of the Carbon in the Rand Banket,' *Trans. Geol. Soc. So. Af.*, Vol. XIII, 1910, p. 74), and also that the solutions containing the pyrite had evidently worked their way in along the original lines of the stratification; and, further, that since there seemed a much greater tendency for these pebbles to have been subjected to the process of replacement than for the quartz pebbles, that the pyrite evidently more readily replaced aluminum silicates than pure silica; also, that it is the more aluminous bands in these pebbles that are the most readily and the first to be replaced. Young, in discussing this paper (*Proc. Geol. Soc. So. Af.*, 1911, to accompany Vol. XIII of the *Trans.*), opposed these opinions. However, the above facts demonstrate their truth. Sullivan has shown that the natural silicates precipitate the metals from solution. Silicates are far more soluble and readily attacked than ordinary quartz; not only are they soluble in sulphuric acid, while quartz is not, but we know that in nature the feldspars (double silicates) in granite are readily attacked and that they are sometimes replaced by cassiterite, while the quartz is unattacked. Lindgren has pointed out (*loc. cit.*) the frequent development, by replacement, of cubes of pyrite in shale; also, he directs attention to the frequent development of pyrite in fine-grained compact argillites, after the hardening and metamorphism of the rock, at a time when it was exposed to mineralizing solutions that were producing ore deposits in adjacent fissures. The writer admits that there is one particular silicate (chloritoid) in the banket that seems, on first consideration, to have been less liable to metasomatic change than the quartz; this is merely an exception, and does not affect the general argument. However, the chloritoid is a secondary mineral, probably deposited as a consequence of the same agencies and about the same time as the pyrite. The way in which the pyrite and chloritoid are often intergrown and interlocked suggests simultaneous growth (see W. H. Weed, 1903, *loc. cit.*, p. 554). It is suggestive that chloritoid also occurs in some of the dikes. The writer had a slide cut from a specimen of a small dark-green basic dike from the North Randfontein mine, and was astonished to find that it contained a considerable amount of chloritoid; and his determination of this mineral was supported by W. W. Watts and C. Gilbert Cullis who afterward examined the slide. Young (*loc. cit.*) maintains that those portions of the pebbles that were the more easily replaced were not aluminous but merely finer grained, and that the smaller the grains of quartz the greater the extent of the sub-capillary spaces along which the mineralizing solutions found their way. Van Hise ('The Genesis of Ore Deposits,' 2nd Ed., 1902, p. 780) has explained that the difference between pervious and impervious strata is "that pervious strata have openings of capillary or supercapillary size, while the openings of impervious strata are subcapillary." The fallacy of Young's latter argument is therefore at once apparent; especially is this so when one considers that it was the conglomerate beds (that is, beds having openings of supercapillary size) which the solutions chose, as offering lines of least resistance, for channels of maximum

¹¹⁹The term 'metasomatic pseudomorph' signifies a replacement product in which the original form (and generally speaking the original volume, or approximately so) of the substance replaced is preserved. The term was first used by Naumann, and, as Lindgren points out, it was the first introduction of the word 'metasomatic' in technical literature. See 'Mineralogie,' Naumann-Zirkel, 10th Ed., Leipzig; also, 'Metasomatic Processes in Fissure-Veins,' by W. Lindgren in 'The Genesis of Ore Deposits,' 2nd Ed. (1902), pp. 501-502.

have been formed by replacement of the matrix, or of the matrix and pebbles, seem to be far more frequent than those that have only replaced quartz pebbles. These facts, taken in conjunction with the further fact that by far the greater number of the pebbles of the bankets are of quartz and that the proportion of the angular slaty pebbles present is very small, shows that pyrite more readily replaces silicates, such as those of aluminum and the alkalis than it does quartz.

Original Substances

The substances that have been replaced, in the order of replacement observed, are slaty quartzite, the material of the banket matrix, ordinary quartzite, and pure silica in the form of quartz pebbles. The three first consist of quartz together with a small proportion of silicates, chiefly those of alumina and alkalies.¹²¹

Posepny remarks that the original substance of most pseudomorphs was composed of soluble minerals such as carbonates, sulphates, chlorides, etc., hence also metamorphic or metasomatic deposits are especially frequent in soluble rocks like limestone and dolomite.¹²² The new material has usually replaced a more soluble substance. In the cases just considered, a material that under ordinary conditions is more soluble has replaced the less soluble. The existence in the banket at the Meyer & Charlton mine of calcite pebbles that were pseudomorphs after quartz pebbles, has already been noted.¹²³ This was a case in which some of the quartz pebbles of the banket were replaced by a material still more soluble than iron pyrite. Pyrite nodules occur in the chalk of the Upper Cretaceous formation of England, many of which have been formed, or partly so, by the replacement of the silica of sponge spicules. Another example (well known on account of its bearing on the formation of flints) of a substance, less soluble under ordinary conditions, having been replaced by a more soluble is that of the particular

circulation. They served the part of fissures in which gold, pyrite, and carbon were deposited, as well as chloritoid, and also the secondary silica of the bankets, which is equivalent to the quartz gangue of normal fissure-veins.

¹²³Denny, G., *Jour. Proc. So. Af. Assn. Eng.*, Vol. II, No. 1 (1903), p. 9.

Kuntz, J., *Trans. Geol. Soc. So. Af.*, Vol. VI, Part IV (1903), p. 74. Kuntz was careful to point out that they occurred near a break, which latter was now partly filled by calcite and from which a great amount of water was still flowing. Also, that these calcite pebbles diminished in number as distance from the break increased; and that as they gradually diminished in number and finally almost ceased to occur, pebbles could be found consisting partly of calcite and partly of quartz, the process of replacement becoming more and more incomplete the farther the distance from the break. Compare this description with that of the occurrence of the pyrite 'pebbles' at the Crown Reef mine, the break there being marked by the presence of a dike along which the mineral-bearing solutions ascended. In that case the pyrite 'pebbles' decreased in number and finally almost ceased as distance from the dike increased.

kind of sponge known as *stauronema*.¹²⁴ The hydrated silica (or opal) of which its skeleton was originally composed has, in many cases, been replaced by carbonate of lime. By this discovery it was proved that the opal of organic skeletons may enter into solution in sea-water.¹²⁵ Confirmation was obtained by the existence of intermediate stages in which parts of skeletons had escaped solution, and the residual silica, deprived of water, was recognized under the microscope. However, chemists and geologists at first, despite the evidence, were loath to accept the facts, showing that so insoluble a substance as silica had been replaced by so soluble a one as calcium carbonate. The difficulty was largely due to the distinction between the hydrated, more soluble form of silica and quartz not being sufficiently borne in mind. Even when this is considered, the difficulty still remains of the far less solubility of hydrated silica than of carbonate of lime. There is, however, no doubt about the facts.

Replacement of Quartz by Pyrite

Petrologists have long been forced to recognize that quartz can be metasomatically replaced by pyrite.¹²⁶

Pyrite is readily soluble compared with such substances as silicates, and still less soluble quartz. However, for the metasomatic changes just described to have occurred in the banket it is evident that under the conditions then existing, the silicates and quartz were more soluble than the pyrite, consequently the two former went into solution, while the latter was precipitated. This knowledge may help to disclose what those conditions were. The fact that quartz and quartzite pebbles have been replaced, as well as the quartz and silicates of the matrix, indicates that the solutions that dissolved them and that also contained the replacing material were chemically active, suggesting that they were at high temperatures and under great pressures.¹²⁷

¹²⁴Sollas, W. J., *loc. cit.*

¹²⁵The silica obtained, both by this pseudomorphic process and by direct solution of sponge spicules, is then available in solution for the formation of flints by means of, first, a directly opposite process to that described above, namely, the replacement of the carbonate of lime organic skeletons by crystalline silica; and then, second, the deposition of silica by which the silicious chalk with mingled remains of sponge spicules, opaline and crystalline, are cemented together; and finally, the pores of the flints are closed by the continued deposition of silica. (See Sollas, *loc. cit.*)

¹²⁶Naumann-Zirkel, 'Mineralogie,' 10th Ed., Leipzig.

Lindgren, 'Metasomatic Processes in Fissure-Veins,' in 'The Genesis of Ore Deposits,' 2nd Ed. (1902), p. 502.

¹²⁷In this connection, it should be borne in mind that when these changes occurred, what, owing to great denudation, is now the surface may have been many hundreds of feet below what was then the surface. In which case it is easy to understand that the temperatures and pressures prevailing in what was then deep-seated ground, but which has now been brought within the reach of the miner, may have been great. Lindgren (*loc. cit.*, p. 528), in discussing metasomatism, states that "the replacement is effected by liquid or gaseous solutions which penetrated the pores, cracks, or fissures of the rock. If, as often happens, a perfect cube of pyrite is embedded in a grain of quartz or feldspar, close examination will rarely fail to discover a minute veinlet or fissure leading up to the crystal and through which the solutions found their way. At high temperature many fine-grained rocks seem to be comparatively easily permeable by solutions."

Under such conditions it is readily conceivable that the quartz may have been converted in silicic acid, which even under ordinary temperatures and pressures, is somewhat soluble in water. It may be that under high temperatures and great pressures it is more soluble in water than iron pyrite. The study of these replacements certainly demonstrates that it was more soluble than the pyrite in the mineralizing solutions, whatever they were, to which these changes are due. The secondary pyrite of these replacements, and the secondary pyrite in the blanket generally, indicate the action of ascending deep-seated solutions.¹²⁸ Vogt has shown that sulphides are actually soluble in silicate magmas, especially at high temperatures, and that they are among the first minerals to crystallize.¹²⁹ The pyrite and gold were among the earliest minerals to be deposited in the blankets from the circulating mineral solutions; and chloritoid,¹³⁰ which is intimately associated with the pyrite and gold, was one of the earliest non-metallic secondary minerals; the final precipitate which ultimately sealed up the conglomerate to the further passage of solution, was silica. The latter was deposited as the secondary silica of the blanket, and is comparable to the quartz of normal gold veins. From the abundance of this silica it may be inferred that the solutions (gaseous or liquid) must have been derived, or given-off, from a silicate magma, or rather, from that upper portion of a basic magma in which silica was predominant.¹³¹ This explanation certainly helps to account for the dissolution of the silica and the precipitation of the pyrite.

Summary.

Thus, the study of the pyrite replacement in the

Rand blanket, where the new mineral has had to make room for itself by solution of the host mineral, leads to the following conclusions:

That the pyrite 'pebbles' of the blanket occur as metasomatic concretions and also as metasomatic pseudomorphs; and that the small particles, grains, or crystals of pyrite scattered through the matrix, and frequently occurring in the pebbles, are also of metasomatic origin.¹³² When the 'pebbles' were formed, there was no increase of volume. The original internal structure of the replaced mineral is often faithfully preserved and can be seen in thin sections under the microscope. Thus the interchange took place by equal, or approximately equal, volumes. Many of the 'pebbles' underwent contraction, the relative amount of which was small and was satisfied by cracks, either quite irregular, or definitely oriented, producing radial or concentric structures; or by shrinkage spaces round portions of the circumference; or by both. These became filled with secondary fibrous crystalline silica. The habit of this silica suggests that its deposition was simultaneous with the contraction of the pyrite, the fibrous structure being due to tensile stresses set up by the contraction of the latter during the crystallization of the silica. This leads to the further conclusion that there was no interval in which open spaces existed. The metasomatic changes by which so insoluble a substance as quartz¹³³ has been replaced by such a soluble one as pyrite¹³³ indicate the agency of chemically-active solutions; the radiate and concentric structures, so often exhibited, are just such as would result from the contraction on cooling of a heated body; and the replacing substance is a sulphide,¹³⁴ and sulphides are generally deposited from ascending deep-seated solutions; these three considerations, and lastly the mode of occurrence generally, and in particular the association of the 'pebbles' with dike intrusions, all suggest that these pyrite bodies are the result of the work of solutions (either liquid or gaseous) at high temperatures and under great pressures ascending from great depths.¹³⁵

(To Be Continued.)

Public lands restored to entry in September covered an area of 750,000 acres, of which 525,747 acres were in Montana and 214,742 acres in New Mexico.

Gold output of the St. John del Rey mine, Brazil, was worth \$168,000 in September, an average of \$11.16 per ton.

Unfilled orders of the Steel Corporation at September 30 were 5,003,785 tons.

¹³²There is also perhaps a little pyrite in the pebbles that was in the material of which they are composed before the blanket was formed.

¹³³Under ordinary conditions.

¹³⁴Sulphide ores are generally deposited by ascending waters. See T. A. Rickard, *loc. cit.*; Posepny, *loc. cit.*, p. 107.

¹³⁵It will do no harm to remark again that Lindgren, in discussing metasomatism, writes: "The replacement is effected by liquid or gaseous solutions which penetrated the pores, cracks, or fissures of the rock"; and also, "at high temperature many fine-grained rocks seem to be comparatively easily permeable by solutions." (W. Lindgren, *loc. cit.*, p. 328.)

¹²⁸T. A. Rickard, in his paper, 'The Formation of Bonanzas in the Upper Portions of Gold-Veins' (in 'The Genesis of Ore Deposits,' published by the Amer. Inst. Min. Eng., 2nd Ed., 1902, p. 737) writes: "Thanks to Prof. Van Hise and Mr. Slichter, whose work he utilizes, we have now arrived at a comprehensive conception of the underground circulation, which emphasizes the conclusion that sulphide ores are generally deposited by ascending waters."

See, also, Posepny, *loc. cit.*, p. 107.

¹³¹Arrhenius, S., 'Worlds in the Making' (Harper Bros., 1908), pp. 16 and 20. Apart from this consideration, however, the cooling of the neighboring dikes would be sufficient to account for a great deal of silicification. Spurr has stated that "upon the cooling of an igneous intrusive rock, however, what might be called a forced segregation takes place. As the rock becomes solid, those materials which are 'left over' are expelled, and find their way into the neighboring rock, or along the fissures of the igneous rock itself. These 'left-over' materials consist chiefly of water, which is usually highly silicicous, and contains a great variety of other mineral matters in solution, and also, very commonly, an unusual quantity of gases." ('A Consideration of Igneous Rocks and Their Segregation, etc.,' by J. E. Spurr, *Trans. Amer. Inst. Min. Eng.*, Vol. XXXIII, 1905, p. 323.)

Lessons of the Year in Our Mining Industry

By J. A. HOLMES

*Our mining industry, already larger, is also growing more rapidly than that of any other great country. During the past century the value of our mineral products for each ten years has almost doubled that of the preceding decade. And while this large increase will probably continue, though at a diminishing rate, the steadiness and continuity of this growth is but one of the evidences that for many years to come the industry will continue to grow in magnitude and national importance.

Importance of Mining

During the year there has come to be a more general recognition of mining as one of the two (agriculture being the other) great foundation industries of the nation. All products of the mine become at once articles of interstate commerce, which no state can reserve unto itself, but which must serve a higher or a larger purpose, namely, the welfare of all the states; and under the recent decisions of the highest courts of the land, mining is thus recognized as a great national industry.

But notwithstanding these facts, and the fact that this most hazardous of our great industries, including with it metallurgical operations, gives employment to more than 2,000,000 men; contributes to our national wealth yearly, products valued at more than \$4,000,000,000, which furnish more than two-thirds of our total freight tonnage, out of which we build and operate our railways and steamship lines, our telephone and telegraph lines, our buildings and our highways, develop heat and light, and operate our factories, and which in a thousand ways contributes to the welfare and the very life of the nation—this great national industry, of such vital importance to all the people, is receiving but tardy and inadequate recognition and aid from the legislative and administrative branches of the general government.

Speculative and Dishonest Features

The speculative and dishonest features of mining are disappearing. We are getting farther away from Mark Twain's definition of a mine. Great ore deposits like those now being developed at Juneau, Alaska, extensive areas of gold-bearing gravel, or the coalfields are, preliminary to mining operations or the sale of stock, being prospected today with such care and thoroughness that mining operations may be entered upon with as much certainty of results as would be true of an investment in a building, a manufacturing plant, or farming. Only the investor need see to it that he is dealing with honest and experienced men. The enforcement of postoffice regulations, and various state laws, enacted at the request of the American Mining Congress, is doing much to check the dishonest mine promoter; and with these agencies the Bureau of Mines is coöperating as far as it can do so. The

opening up of large low-grade orebodies, heretofore generally and necessarily ignored in our great mining states, is another phase of mining development which will yield more certain returns on the capital invested, and will, therefore, give greater safety to the small as well as to the large investor in mines, and this development will also give greater stability to labor conditions.

The discovery and development of these large low-grade orebodies, as is true of iron and coal, bring about conditions which are not such as to interest or encourage the ordinary prospector. But with the needed discovery of more efficient methods for working these low-grade ores, the interest in them will increase; new prospecting methods will be developed; new prospectors will traverse the hills; and in many regions a new life for mining, more stable and more permanent, will result. In the placer regions of Alaska the old-time prospector still has his fields of activity. Every year he enjoys a new stampede. Now and then he makes a stake, and usually he reinvests all, or a large part, of his savings, in another find. It is the poor man's field, with a future as well as a past. In recent stampedes, however, there has developed a practice which threatens to seriously interfere with, if it does not destroy, prospecting of the old type; that is the practice, which I believe to be both undesirable and contrary to the spirit of the law, under which wealthy individuals and large corporations rush their well equipped hired men to a new discovery to stake claims, each in his own name, and then immediately transfer such claims to their employers.

Safety and Rescue Work

It is as to mine safety that the year's experience teaches the most important lessons. The decided progress in reducing the loss of life in coal-mining during the past few years gives encouragement as to what may be further accomplished along this line. Mine-owners, miners, and mine inspectors all deserve commendation for their good work during the year in behalf of mine safety, mine rescue, and first aid work. But we should all realize that we have but begun the good work. The recent awful disasters in Wales and Germany, and that at Stag Cañon in this country, indicate the need of new and greater efforts to prevent the occurrence of similar disasters during the new year upon which we are now entering. We must take no chances. Let no man think that his mine is safe. Most of the disasters have occurred in our 'best mines.' We must give safety the benefit of every doubt. Every mine-owner, and every miner in his employ, should coöperate in a determined effort to prevent even the smallest of accidents; for it is often the small accidents that inaugurate large disasters. Let no man be careless where the lives of men are at stake. Both operators and miners should and will welcome the most rigid inspection and enforcement of law

*Address before the American Mining Congress, Philadelphia, October 24.

by the state's inspectors. With all efforts for greater safety, the Bureau of Mines will coöperate to the fullest possible extent.

There has been progress in the movement for the prevention of waste in mining and metallurgical operations. The Bureau has been endeavoring to collect reliable data as to the nature and extent of such waste, and possible methods of lessening or preventing the same. That this waste is large, all admit; but few, however, appeared to realize what now seems to be the case: that the aggregate value to the nation of the sum total of all the waste of mineral products may be said to approximate a million dollars per day. The special efforts of the Bureau will be along the lines of finding out what part of this waste is preventable under existing conditions, and how this waste prevention may be brought about to a larger extent each year as new and more favorable conditions develop. Already some progress has been made, the most notable example being the saving during the first year of natural gas and oil having an aggregate value equal to many times the total cost of the Bureau from its inauguration to the present time. The results of pending inquiries and investigations indicate the possibility of much larger future yearly waste prevention in connection with both mining and metallurgical operations.

Appropriation for Metal Mining

Since the last meeting of the Mining Congress a new organic act for the Bureau of Mines has been enacted by Congress. The duties and purposes of the new Bureau have been enlarged to the full scope asked for by its friends; and at last metal mining has been recognized in federal legislation as an important branch of the mining industry. Meanwhile, also, Congress has appropriated \$100,000 for investigations and inquiries relative to safety and waste in the mining and treatment of ores and other mineral substances. These inquiries and investigations, relating to all mineral resources other than coal, are now in progress in a considerable number of states where mining, quarrying, and metallurgical operations are under way. The other special appropriations for the work of the Bureau are \$135,000 for testing the coal and oil used by the general government; and about \$360,000 for investigations of mine explosions and other accidents in coal mines.

I am aware of many criticisms of the Bureau in different parts of the country because of its failure to do numerous things of which there is serious need, and which if done would aid greatly in better safeguarding the health and lives of miners, and would be generally helpful in the prevention of waste, as well as in the general development of the mining industry. I know, however, that while agreeing with our critics, these things ought to be done, and that they come within the scope prescribed by Congress for the Bureau, members of the Mining Congress all realize the inadequacy of our appropriations for doing even the many things needed and that have to do directly with the saving of life. It is more unfortunate, however, that our inability to do many of these things at the opportune time

tends to discredit all our work and even the movement for greater safety among the miners, who appreciate less fully the cost of such investigations and whose good will, confidence, and coöperation is essential to the success of all our efforts.

But while the situation is at times profoundly discouraging, there is nevertheless good evidence of progress. The movement for safety has appreciably reduced the loss of life in coal mines during the four years since our investigations were begun. The coöperation of both mine-owners and miners with the Bureau in this work is now more effective than ever before. In the work for the prevention of waste, the saving during the first year has exceeded in money value many times the total cost of the Bureau. Congress at its last session authorized an appropriation of \$500,000 for new laboratories for the work of the Bureau at Pittsburgh. And it is hoped that in the near future this recognition and aid for the mining industry from the federal government, so much needed and so long demanded by the American Mining Congress, may be more nearly commensurate with the sacrifices and national importance of the industry.

Mining in Sweden

According to the annual report recently issued by the Bureau of Commerce and Industries (Kommerskollegium) of the Swedish government, 300 iron mines were being worked during 1912. The total output of these mines was 6,699,226 metric tons of ore, of which 4,266,821 tons came from the mines in Norrbotten, the northernmost part of Sweden. Thirty-four refining plants were in operation and 1,215,318 tons of raw ore was treated, yielding 520,710 tons of *slag* or refined ore, valued at \$1,300,000. Compared with the production of 1911, this was an increase of about 39%. The production of briquettes of refined ore was carried on at 17 different works, the combined output of the year amounting to 288,553 tons. The production of pig iron amounted to 699,816 tons, thus showing an increase during the year of 10.3 per cent. At Höganas, 3979 tons of 'iron sponge' was produced. During 1912, according to the report, the Swedish steel plants produced 63,900 tons of bessemer ingots, 238,850 tons of martin ingots, and 4850 tons of cast martin steel. The total production of forged iron and steel amounted to 509,244 tons valued at \$21,560,600.

With regard to the mining of other metals, results in 1912 were reported as, 2877 tons of silver-lead ore, 3059 tons of copper ore, and 50,000 tons of zinc ore. The coal mines in southern Sweden produced 360,291 tons of coal of different qualities, 135,773 tons of fire clay, and 58,846 tons of clinker clay. The value of the coal output was estimated at \$750,400. Of the precious metals, 67,300 pounds of gold was obtained and 2114 pounds of silver. The copper ore mined yielded 4352 tons.—*Daily Consular Report*.

There were 58 gold mines operated in the Orenburg district of Russia in 1912, from which was mined about 170,000 tons of ore yielding approximately 43,000 oz. of gold.

The Voice of the Prospector

The fact of the approaching extinction of the prospector has been urged so persistently, indeed so many autopsies have been held over his still quivering form, that possibly a few words from the prospector himself may be in order. We abstract a few from among a number of recent letters received from our friends who are out on the dusty trails that lead, as we all hope, to some golden Goleonda.

One man, writing from Idaho, reflects the cheerful spirit that overcomes obstacles: "I raise milch cows, purchase calves, breed them when ready and sell them when they are fresh; I keep 40 to 50 and it keeps me in a tolerably good grubstake—about \$175 to \$200 per ton. If only there were tons enough! I have mined more or less for 25 years. I am looking for a paying mine of my own and I will find it some of these times.—W. C. F." We sincerely hope he may, as also C. M. M., who writes from Oregon that he is a "lifelong prospector 70 years old, badly battered, but still hopeful." L. S. writes that he is starting on a prospecting trip, and as his subscription will expire while he is gone, sends a draft now. Our business manager says that one who is so careful about small business matters can hardly be the 'dreamy unpractical cuss' that many have pictured the prospector.

Prospector and Prospects

G. M., writing from Utah, has the following pertinent remarks to make: "Just a word about the prospector and prospects. My opinion is, that the reason there are so few genuine prospectors in the field and so few new mines being found is not because of the attitude of the Forest Service, but because the old-time mining camp storekeeper is almost a thing of the past. I mean the ones who would put up a grubstake or carry a lessee for a year or two without demanding a note with two or more signatures before he could get a sack of flour. There is also that vast army of mine and mill workers who delighted to take a chance on a prospect or invested their cash in mining stocks; they are out of the game altogether, for with the high cost of living it keeps them busy making both ends meet. We all know that with rare exceptions men of large means do not care to buy up or develop a prospect, probably the mining industry would flourish if they bought up good prospects and developed them, but I suppose that would not be good business (too much chance)."

J. W. A., who is at work in the Southwest, says: "Believing that Mexico's present trouble is Arizona's big opportunity, I have been trying to induce some of these American and English mining men to come here and put churn-drills at work on a large leached capping that I firmly believe is a disseminated deposit, but I find a prospector's letters do not count for much, yet he found all of the mines we have today. By the way, would it be possible for you to call attention of Eastern mining men and people looking for good mining properties to the fact that there is as good mining ground in Arizona that has never been scratched as was ever found in Mexico, and there are no revolutions in Arizona to

interfere with the business of mining?"

The same problem, why it is difficult to sell a good claim, is touched upon by F. P., who is owner of an Arizona property that we have known of as producing high-grade ore at intervals since 1893. He says: "As owner and developer of a group of mines, upon which I have concentrated my energies for the past 22 years and which is for sale, it would be of great interest to me if you could throw some light upon the machinations of the great mining companies in their negotiations for a purchase. How is it, that after proceedings are broken off with one of them, a deal with another company when affairs have progressed apparently to a climax is suddenly blocked? Does not this point to a mining trust?" The question raised is too large to discuss here. Answering briefly, we can state with assurance that there is no mining trust. Engineers and mining men do exchange information and the knowledge that a property has been examined with unfavorable results by one, often becomes the common property of many. In general, we believe the difficulty that F. P. has met is due to lack of consideration of the poor by the rich rather than any deliberate combination. The very wealthy men get the notion that anything worth while is bound to come to them in time and that they can afford to prolong negotiations or to throw up options with a view to bearing the price; that in general, if Tom does not get the property, Dick or Harry will, and the next may be Tom's turn. Occasionally both lose, and we can name a number of cases where Dick paid more than Tom's option called for. If it is any consolation to F. P., we can assure him that he is not the only sufferer. We know excellent engineers who have been caught with valuable options in this same way; and that, too, by men for whom they had long worked and who had always followed their advice promptly when the relation was the usual one of client and adviser. However, we had not intended to be drawn into the matter, purposing rather to present to others the prospector's own point of view as to the existing situation. True to his tradition, he is still yielding to the lure of the pick and pack; a little older, a little wiser, recognizing more clearly perhaps the difficulties to be met, but with an abundant store of the cheerful optimism which has made the West and will renew it time and again.

Gold and silver production of the Hauraki Peninsula, North Island of New Zealand, during the first seven months of 1913 totals \$2,450,000. The August returns from the principal mines are as follows:

	Tons.	Value.
Komata Reefs	*200	\$ 1,400
New Zealand Crown	1,468	11,000
Talisman	4,280	110,000
Waihi	14,735	105,000
Waihi Grand Junction	8,800	72,000
Waihi-Paeroa Extraction	†11,450	17,300

*Closing down.

†Treatment of tailing from Ohinemuri river.

The Waihi company has paid dividend No. 80, bringing the total paid to \$21,873,600.

Coal mine fatalities in the United States in July totaled 1437, as against 1419 in July 1912.

The Herreshoff Roasting Furnace

In the new smelting plants of the Arizona Copper Co., at Clifton, and the Calumet & Arizona Copper Co., at Douglas, Arizona, the roasting of concentrate preparatory to smelting in reverberatory furnaces is done in 6-hearth Herreshoff roasters. As the Herreshoff in its original form was a modification of the MacDougall roaster to meet the conditions required in the roasting of pyrite to yield SO_2 for the manufacture of sulphuric acid, its use in copper smelting practice is of great interest. Eight 21½-ft. roasters have been built for the Arizona Copper Co. and 12 of the same size at the Calumet & Arizona plant. The most notable features of these are: the use of air-cooled rabblers; the return of the air thus heated to the lowest hearth, thereby increasing the thermal efficiency of the roaster and allowing the roasting, without the use of fuel, of concentrate lower in sulphur than is the usual practice; and the use of rabblers so designed that a single casting will operate in any position on the rabble arm, thus doing away with the necessity for keeping a variety of teeth in stock.

Furnace Construction

The accompanying illustration shows the construction of the furnace. The outer shell is made of ⅝-in. steel plate three courses high, the outer diameter being 21 ft. 7¼ in. The horizontal seams are 3-in. lap, riveted with ¾-in. rivets, with 5-in. pitch. The vertical seams are butt joint, triple riveted, with butt-plates, 5/16 by 16½ in., inside and out. This shell is 19 ft. 5 in. high and is lined with 8-in. fire brick. There are six superimposed hearths, the top of the furnace being also used as a drying hearth. Each hearth is made of a single arch of 6 or 8-in. fire brick (as shown in illustration), the spring of the arch being 10½ in. The hearths for outside discharge have 54 openings, 18 by 14 in. each, around the periphery; those with inside discharge have an 8-ft. diameter circular opening at the centre. The central opening on the other hearths is merely large enough to permit rotation of the central shaft, which is 42 in. diameter. Each hearth is provided with six doors on the outside, except the topmost, which has but four. Each door is 24 by 16 in. and is fitted so as to make a tight joint.

The central shaft is made in three sections, each approximately 6 ft. long. These are fastened together with tongue-and-groove joints, and bolt heads and nuts are protected by pockets which can be filled with refractory material. The rabble arms are similarly connected with the central shaft. Within the shaft is an 18-in. steel tube, bolted to nozzle outlets at each arm. Air under pressure is forced through this tube, passes to the outer end of the rabble arm, and back to the central shaft. The rabble arms are connected in parallel so that each arm receives its due quota of cool air. The central web which causes the air to pass to the end of the arm before returning also greatly adds to the strength of the arm. The heated air is taken off at the top and brought back through channels in the outside walls to the lower hearth. The heat which it has absorbed

is thus transferred to the lowest hearth and by decreasing the cooling effect of the air admitted for combustion allows the roasting without extraneous heat of material much lower in sulphur than would otherwise be the case. On the other hand, material with a given sulphur content will yield more heat and will therefore roast faster than without heat conservation. The rabble teeth are so cast that the lug at the top which fits against the arm is at different distances from the centre line on the right and left side. When a uniform series of teeth are placed upon the rabble arm this causes each tooth to assume a different angle, according to its distance from the centre, and the increased work which the inner teeth have to do is thus automatically compensated. The

THE HERRESHOFF FURNACE.

outermost rabble is kept in place by a single drop-pin. This is of special design to provide for the feed from the hearth above, as shown.

Path of Ore Through Furnace

The ore is fed upon the upper drying hearth from hoppers. Just beneath each hopper is a steel plate and the ore is caused to feed by a rotating finger which passes between the hopper and the plate. The ore thus drawn out falls upon the top of the furnace, and is worked to the periphery by a set of rabblers. These are simply dropped into place on the rabble arm and can be removed or put in place without stopping the furnace, thus permitting easy changes in the rate of feed. This is also controlled by cast-iron sleeves at the end of the feed hoppers. By raising or lowering these, the rate of feed may be altered as desired. The dry ore passes down to the first hearth through a series of hoppers at the

outer edge which are provided with adjustable plugs to prevent the escape of gases. The space between the top of the furnace and the central shaft is closed with a sand seal, while on the lower hearths the calcine serves as a seal. The gases escape from the furnace through two exits, having a combined area of 18.8 sq. ft. The flues which convey the gases to the stack are so arranged that the flue-dust is automatically returned to the lower hearth, thus eliminating the labor cost of handling flue dust. The rabble arms are driven at one revolution per minute by a 72-in. bevel gear. The pulleys and gearing are so mounted on an A-frame that they can be removed for repairs without disturbing the rest of the furnace. The equipment for the roasters at these two plants was furnished by the Pacific Foundry Co., and they were erected under the supervision of C. H. Repath and A. G. MacGregor, who designed the plants.

General Chemical Co.'s Plant

The largest installation of Herreshoff roasters now at work is at the Edgewater, New Jersey, plant of the General Chemical Co., where eighteen 16-ft. furnaces are at work roasting Spanish pyrite for the production of SO₂ for acid manufacture. The operating conditions are scarcely comparable, since in this case it is necessary to secure a gas high in SO₂ and a calcine low in sulphur rather than the larger tonnage desired in copper-smelting practice. Thus a 16-ft. roaster handles only 5 to 6 tons per day, reducing the sulphur content from 46% to 1/2%. The ore is crushed to pass 4 mesh before roasting, and the calcine is briquetted for use in iron smelting. Operating under these conditions, it has been found that only one arm has broken in the past six months with 18 roasters in use. A crew of six men per shift is sufficient for this number of furnaces, including the wheeling of the pyrite from the storage bins to the feed hoppers of the furnaces. Broken rabbles can be replaced in a few minutes, but in the case of a broken rabble-arm a delay of 4 to 7 days is the result, since it is necessary to allow the furnace to cool slowly to the temperature at which a man can enter to loosen the bolts. Some experiments have been made in the developing of a detachable arm, but it has been found that delays from the breaking of rabble-arms are so infrequent that the advantage thus gained is practically neutralized by the increase in construction cost and the difficulty of obtaining an air-tight joint. The total cost of upkeep on these roasters as used at Edgewater, amounts to 10c. per ton roasted. This amount may be expected to vary with the quality of gas, the temperature, tonnage, time of year, and other factors.

Two blast-furnaces are working at the Tanganyika Concessions property at Katanga in Central Africa, and during the first eight months of the year the copper output was over 4000 tons. During July and August the yield was 1900 tons. Fine ore is being briquetted; the first group of Coppee coke-ovens is being built; and the 'technical committee' of the Union Miniere du Haut Katanga is planning a large increase in copper production.

Milling Operations at the Eldorado Banket Mine, Rhodesia

The following figures are from the annual report of the Company for the year ended March 31, 1913:

Crushing plant:	
Number of stamps in operation.....	20
Running time of stamps, days.....	342.58
Duty per stamp per day (estimated) tons.....	5.25
Chilean mills in operation	2
Running time of Chilean mills, days.....	331.89
Duty per Chilean mill per day (estimated), tons.	77.15
Grinding pans in operation	8
Running time of grinding pans, days.....	333.89
Average assay value of ore milled, per ton.....	\$12.93
Total gold content of ore milled, ounces.....	56,290
Yield in fine gold from stamps and Chileans, ounces (72.61%)	29,646
Yield in fine gold from grinding pans, ounces (27.39%)	11,181
Total yield in fine gold from mill, ounces.....	40,827
Yield per ton milled, dwt.....	9.366
Percentage of assay value.....	72.599

Cyanide plant:	
Tonnage treated	88,209
Gold content, heads, before treatment, ounces....	15,625
Gold content, tailing, after treatment, ounces....	3,565
Theoretical extraction, per cent	77.18
Actual extraction, per cent	77.32

	Percentage of gold content.
Recovery by:	
Stamps and Chileans	62.65
Grinding pans	19.87
Cyaniding sand	13.59
Cyaniding slime	7.65
Total	93.76
Left in sand residue	3.94
Left in slime residue	2.33
Difference	0.03

Total	100.00
Working costs: Per ton.	
Mining	\$2.32
Ore transportation and crushing	0.16
Milling	0.85
Fine grinding	0.44
Cyaniding (including accumulated sand).....	0.60
General charges mine	0.40
General charges Bulawayo	0.19
Total (excluding development)	\$4.96
Development	0.72
Total cost (including development).....	\$5.68
Gold production, 52,908 oz. fine gold.....	12.40
Working profit	\$6.88

The profit on all operations was \$576,000, and two dividends of 72c. per share each were paid. The ore reserves of the mine are estimated at 74,826 tons, averaging \$16.40 per ton.

At the Lena Goldfields property, Siberia, 691,011 cu. yd. of gravel was mined and hoisted from October 1, 1912, to August 20, 1913. During the period, 695,943 cu. yd. was washed, yielding gold worth \$4,896,000.

In 1912, according to figures gathered by the U. S. Geological Survey, 143 of the cities of the country having a population of 35,000 or more spent \$919,809,054 in building operations.

Handling Ore From Stock Pile at Miami

The Miami Copper Co. accumulated 18,000 tons of good ore in a stock pile in a gulch in the course of its preliminary work, and recently it was proposed to bring this ore from the stock pile to the overhead bins at the mill. After considering various methods of

tact with the ore as shown in Fig. 1. The bucket is filled by pulling it into the material by means of a pull cable attached to the front. When it is filled, the track cable is pulled taut by means of a tension mechanism. By tauting the track cable the bucket is lifted clear of the pile and it is then hauled up the inclined track cable by means of the pull cable. At the point of dumping, an adjustable button on the track cable is provided. A traveler block coming in

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

handling the material it was decided to install a new type of cableway excavator known as the Shearer & Mayer. The decision was based on the following advantages claimed for this excavator: it will operate over a span of 500 ft.; it will dig, elevate, and convey in one operation; the line of operation can be readily changed; no power is required to return the empty bucket, as the latter returns by gravity; no time is lost in dumping, as the bucket is dumped by a continuous forward movement.

The excavator as erected consists of a $\frac{3}{4}$ -cu. yd. capacity scraper bucket, suspended from a carriage which travels on an inclined track cable. The bucket and carriage travel down this inclined track cable to the point of digging when the track cable is slackened and the bucket is thus allowed to come in con-

contact with this button dumps the bucket automatically.

A two-drum hoist operates this excavator. One drum operates the tension mechanism and the other the pull cable which loads the bucket and pulls it up the inclined track cable and also dumps the bucket. Fig. 2 and 3 show the loaded bucket traveling up the inclined track cable. Fig. 4 shows the loaded bucket entering tipple. The cableway excavator was put in operation early in June, and from the time it was put in operation to June 30, it handled approximately 10,000 tons. It frequently handles 300 tons per 8-hour shift. The machine has been found admirably adapted for this class of work. The excavator was designed and furnished by Sauerman Bros. of Chicago.

Possible Applications of Electric Furnaces to Western Metallurgy

By DORSEY A. LYON and ROBERT M. KEENEY

*As has been repeatedly pointed out, the electric furnace was not developed for the purpose of competing with the combustion furnace in the domain of ordinary metallurgy, but rather to do for metallurgy what it is not possible to do with the combustion furnace, either because of existing local conditions or because a higher temperature or method of heating is required than it is possible to obtain in the combustion furnace. Only those applications of the electric furnace which are strictly within the domain of metallurgy, and where the electric current is used as a thermal agent only, will be discussed here. Also, there will be discussed the use of the electric furnace in the smelting of ores, having in mind especially those conditions which are to be found in the western part of the United States. With the exception of the production of aluminum, iron, and ferro-alloys, electric furnace metallurgy is largely in the speculative or experimental stage at the present time.

The Electric Furnace for Smelting Iron Ores

As is well known, of the coke charged into an iron blast-furnace, only about two-thirds is used for producing the heat necessary for carrying on the process, while the other one-third is used as a reducing agent. Therefore, if the electric furnace is used for the smelting of iron ores, only enough carbon has to be supplied to unite with the oxygen of the ore; in other words, to reduce it, and for this reason the smelting of iron ores in the electric furnace is of much importance to the western coast states, for there are found comparatively large iron-ore deposits, but not suitable blast-furnace coking coals, and so the cost of coke makes ordinary blast-furnace smelting prohibitive. However, it is necessary to supply carbon in some form as a reducing agent, and even though only one-third as much carbon is required for this purpose as is required in ordinary blast-furnace practice, it may be impossible to obtain this smaller amount at such a cost as will permit of the use of the electric furnace.

So far only coke and charcoal have been tried to any extent as reducing agents in the reduction of iron ores in the electric furnace, and of these only charcoal has proved satisfactory. This has been shown by repeated trial runs at Trollhättan, and has been forcibly demonstrated by the fact that the plant at Hardanger, Norway, where coke was used as a reducing agent, after being in operation for about nine months was forced to close, due to the fact that nowhere near the same amount of pig iron could be produced per kilowatt-year of electrical energy expended as can be produced when charcoal is used. That this is true is doubtless due to the fact that coke is a much better conductor

of electricity than is charcoal, especially after it becomes hot. For this reason, when using coke the resistance of the charge becomes lowered, and, as the smelting in the electric iron reduction furnace is done by the heat produced by the resistance which the electric current meets with in passing through the charge between the electrodes, more electrical current (amperes) is required to produce the same amount of heat. Likewise, as stated by Crawford, the electrical conductivity of coke "is so good that much of the current passes between the electrodes in the upper part of the furnace. The smelting zone is thereby raised, and the furnace runs hot on top, with attendant melting of the arches of the roof of the crucible, and cold at the bottom. Further, the coke, because of its density and high crushing strain, does not break down like charcoal as the burden descends, hence less surfaces of carbon are exposed to be oxidized by the ore, and there is a less intimate mixture of the two.¹ Reduction of the ore takes place more slowly, the silicon in the iron is lowered, the consumption per ton increases, and the efficiency of the furnace is reduced."

Situation Requirements

Inasmuch as either charcoal or coke are the only practical reducing agents known at the present time, that is, for use on a large scale, and as it would seem from what has just been stated that it is impractical to use coke, this necessarily limits the electric iron reduction furnace to the use of charcoal. Hence it is necessary that such a furnace be situated in close proximity to a well timbered region, where charcoal as well as electric power can be produced at a low cost. If this be true (and it undoubtedly is at the present time), it is unfortunate, especially as regards the situation in southern California and in other of our western states, where there are quite large iron deposits of first-class ore, but where coke is too expensive to permit of ordinary blast-furnace smelting, and where the use of charcoal for electric furnace work is entirely out of the question, as there are no forests to furnish the wood necessary for its production. On the other hand, crude oil is generally more or less plentiful and comparatively cheap in such districts, especially in California. Aside from its possible use in connection with electric furnace work, those interested in the subject have for years been considering the possibility of using crude oil as a reducing agent. That the carbon and the hydrogen of the oil will reduce iron oxides is self-evident, but as yet no one seems to have been able to solve the problem as to how to bring the ore and the oil together at the proper temperature. As a result of a preliminary investigation conducted by the metallurgical department of the U. S. Bureau of Mines on the possibility of using crude oil as a re-

*Abstract from a paper presented at the meeting of the American Electrochemical Society, at Denver, Colorado, September 1913. Published by permission of the Director of the U. S. Bureau of Mines.

¹This intimate mixture is, of course, very necessary where the reduction is almost entirely performed by solid carbon, as is the case in the practice at Heroult, California.—THE AUTHORS.

ducing agent, it seems as if about the only manner in which crude oil may be used for this purpose is to first convert it into a fixed gas and then introduce this into the crucible of an electric furnace, thus preheating the gas to such a temperature that it will effectively reduce the iron oxides as it passes up through the shaft of the furnace. Be that as it may, it is to be hoped that ultimately a suitable process may be devised whereby oil may be used as a reducing agent, and thus broaden the field for the possible application of the electric furnace in the reduction of iron ores; for it is apparent that the electric furnace is limited for such purposes at the present time to those localities where charcoal and electric power are comparatively cheap.

That the electric furnace has been successful in the smelting of iron ores in those districts which are favorable to the same is shown by the fact that ten furnaces of the Swedish type (a total capacity of about 22,000 kilowatts) have been erected in Sweden, Norway, and Switzerland. In this country there is one electric furnace iron plant of two furnaces, with a total capacity of 5000 kilowatts, at Heroult, California. The type of furnace used in California is different from that used in Sweden, due to the fact, that a different grade of iron is desired from that which is produced in Sweden; that is, in Sweden a metal is produced which is low in silicon and carbon and which is particularly well suited to steel making, whereas in California the demand is for a soft gray foundry iron.

As to the quality of pig iron produced in general in the electric furnace, the engineers in charge of the experimental work at Trollhättan made the following statement in their final report: The silicon content does not vary more than in an ordinary blast-furnace. The phosphorus content is lower than with the same quality of charge in an ordinary blast-furnace; this is due to the lower consumption of charcoal. The percentage of sulphur is, however, slightly higher in the electric furnace. The quality of the electric pig iron has been highly commended. It acts particularly well in the open-hearth furnace, and steel made from it is certainly not inferior to steel made from ordinary pig iron.

Ratio of Concentrate to Ore

It has been found that the proportion of concentrate ought not to exceed 20% of the ore charged. This figure, however, does not appear to be final, as in a later constructed and somewhat modified furnace of the same type at the Hagfors Iron Works, 25% of concentrate is used without any difficulty. The power consumption per ton of pig iron varies in proportion to the iron content in the ore. A poor ore and pig iron high in silicon and manganese require more power than a rich ore and pig iron low in silicon and manganese. For such iron the power consumption averages only 2067 kw. hours per ton of pig iron; that is, there is obtained 4.22 tons of pig iron per kilowatt year, or 3.10 tons per horsepower year. The charcoal consumption per ton of pig iron varies from 20 to 24 hectolitres (56 to 68 bushels), depending on the quality of the charcoal and the charge. Coke has been found to be unsuitable for this furnace unless mixed with charcoal.

The consumption of electrodes at Trollhättan has been reduced to less than 3 kg. (6.6 lb.) per ton of pig iron. At Hagfors it has amounted to as much as 6 to 9 kg. (13.2 to 19.8 lb.). This discrepancy is explained by the fact that the electrode consumption is increased in proportion to the higher power consumption for a poorer charge, and is further increased by the more efficient circulation of gases and higher CO₂ content in the gas. The lower electric load per unit of surface at the Hagfors furnaces also contributes to the higher electrode consumption at this plant. The cost of repairs is lower than there appeared at first to be reason to expect. In the manufacture of pig iron containing silicon and manganese the cost of repairs is higher than in producing pig iron with low contents of those elements. At the plant of the Uddeholm company at Hagfors, the gas from the furnaces has been used with very good results for heating the open-hearth furnaces.

Possibility of Smelting Copper Ores in the Electric Furnace

No copper ores are being treated on a commercial scale at the present time in the electric furnace in this country. It is reported, however, that in Norway trial smeltings of copper ores with an electric furnace of 1000 hp. and an estimated producing capacity of 2000 tons per annum have been conducted at the Ilen Smelting Works, Trondhjem, and it is the intention to smelt copper ores regularly at this plant in the electric furnace.

More or less experimental work has been done upon the subject, and, as a result of this work there seems no good reason why copper-bearing ores cannot be as successfully treated in an electric furnace as in a combustion furnace. In all furnaces of the latter class which are used for the treatment of copper ores the fuel used takes no part in the reactions which are necessary for obtaining the desired product, unless it be in the reduction of oxide ores which are smelted alone, that is, without an admixture of sulphides, which is practically an unheard of thing in this country at the present time. For example, in the reverberatory furnace the fuel acts only as a heating agent; in blast-furnace smelting, if what is known as ordinary blast-furnace smelting is used, the coke added to the charge is for the purpose of supplying the heat necessary to raise the charge to such a temperature as will permit of the necessary reactions between the oxides, sulphates, and sulphides present, and to scorify the resultant mass and thus permit of the separation of the slag and matte. In semi-pyritic and pyritic smelting the necessary oxidation of the sulphides and iron is brought about by the oxygen of the air entering the tuyeres, and the coke used is simply for the purpose of supplying the amount of heat necessary for the successful carrying out of the process, which is not supplied by the oxidation of the sulphur and the iron present in the charge at the time it passes through the tuyere zone of the furnace. Such being the case, there seems to be no reason why the smelting of copper ores could not be done as well by electric heat as by that derived from the combustion of coke, especially if local conditions warrant it. As a result of experimental work which has been done by ourselves in connection

with tests which have been made by the U. S. Bureau of Mines, and judging from results which have been obtained by others, it appears perfectly feasible, both metallurgically and commercially to use the electric furnace for the smelting of copper ores.

Lead Ores

The smelting of straight lead ores in the electric furnace has never been attempted either commercially or on a large experimental scale, largely because of the ease and cheapness of smelting by combustion processes. For the smelting of ordinary lead ores, it has no especial application, but in the treatment of complex lead-zinc-silver ores the electric furnace might be profitably used. The roasted ore could be treated in an electric furnace operated at a temperature such that the lead reduced by carbon melts and collects the precious metal values and the zinc is volatilized and condensed.

Electric Zinc Smelting

The use of the electric furnace in the metallurgy of non-ferrous metals has had greater application for the treatment of zinc ores than in the metallurgy of any other of the non-ferrous metals except aluminum and ferro-alloy manufacture. Since 1885, when an electric furnace for the treatment of zinc ores was patented by the Cowles Bros., experimental work has been conducted on the subject. The commercial application of the process, however, has not resulted to any great extent because of the difficulty of condensing the zinc vapor produced under the smelting conditions of the electric furnace. The cause of this difficulty has not yet been definitely determined. With few exceptions the experimental work has not been conducted on a very large scale, and so it may be said that the electric smelting of zinc ores is still in the experimental stage. The special field for electric furnace work in zinc metallurgy is due largely to the low thermal efficiency of the present zinc retort which is given by Richards as only 7%. With the efficiency of the electric furnace varying from 50 to 75%, the difference in the heat necessary for the smelting operations is so great as to permit of a higher cost of electrical energy than is permissible in many electro-metallurgical operations.

Electric Furnace Method of Zinc Smelting

Processes for the electric smelting of zinc ores are of two general classes—first, reduction of zinc oxide and its compounds by carbon and carbon monoxide, and, second, decomposition of zinc sulphide by metallic iron. Examples of the first method are the DeLaval and Johnson processes, and of the latter the Cote-Pierron and Imbert-Thomson-Fitzgerald processes. Reduction of zinc oxide with carbon is based upon the reactions

- (1) $\text{ZnO} + \text{C} = \text{Zn} + \text{CO}$
- (2) $\text{ZnO} + \text{CO} = \text{Zn} + \text{CO}_2$
- (3) $\text{CO}_2 + \text{C} = 2\text{CO}$

The use of iron is according to the reaction

- (4) $\text{ZnS} + \text{Fe} = \text{Zn} + \text{FeS}$

In neither of these processes does the electric current perform any other function than heating. Due to the fact that alternating current is supplied to

the furnace, there is no electrolysis. The process may be performed in either an arc or resistance furnace. One essential difference between the reduction of zinc oxide by carbon in an electric furnace and in a retort is that the retort process is intermittent and the electric process may be continuous. In the electric furnace the charge is added at intervals, as necessary, and the slag is tapped or allowed to run continuously from the furnace without disturbing the operation of the process. The reduction by carbon or carbon monoxide occurs just as in the retort, with the exception that because of the rapidity of reduction in the present designs of electric furnaces, the third reaction does not take place apparently as well in the electric furnace as in the retort, resulting in a greater amount of carbon dioxide in the zinc vapor, which has a bad effect on the condensation. This results in the production of a large amount of blue powder. Various attempts have been made to reduce this, the principal one being the passing of the vapor through incandescent carbon before entering the condenser.

Operations of Smelting

The smelting process consists essentially of two operations, namely, concentration of the zinc to a rich oxide followed by reduction in another furnace. Oxide ore, flux, and carbon used as a reducing material, are charged into the furnace, where most of the zinc and some of the lead are volatilized and condensed partly as metal and partly as blue powder and oxide, containing 54% zinc and 20% lead. This is really a concentration powder, for the blue powder is now mixed with ore and recharged, when a larger percentage of the metal volatilized is recovered as metal. The remainder of the lead, which carries some silver, is reduced to metal in the smelting hearth and is tapped with the slag. Some lead, zinc, and silver passes into a matte and some into the slag. The furnaces are of a modified Siemens type with a shallow hearth, and covered with a roof. A carbon block bottom forms one electrode, while the other passes vertically through the roof. In some furnaces the ore is charged through the roof, in others at one side of the electrode, while others have been designed having a continuous side feed. The consumption of electric current in the experimental run at Trollhättan averaged 2078 kw.-hr. per ton of ore smelted, which does not include resmelting the powder. Two tons of powder were re-treated per ton of ore smelted. A comparison of the resistance furnaces at Trollhättan with the arc furnaces at Sarpsburg shows that while one was as good as the other for the carrying out of the desired reaction, the energy consumption was 70% more in the arc furnace than in the resistance furnace. The consumption of electrodes was also higher in the arc than in the resistance furnace, being 89.2 lb. per ton of ore at Sarpsburg and 69.3 lb. per ton at Trollhättan.

Experiments of Johnson

One of the most persistent investigators of the possibility of smelting zinc ores in the electric furnace is W. McA. Johnson,² who has conducted experi-

²*Met. & Chem. Eng.*, Vol. X (1912), p. 537.

ments on a large laboratory scale for several years.

Johnson's furnace has vertical upper carbon electrodes and a conducting hearth of carbon. Ore is fed in through the roof of the smelting chamber. There are several tap holes at different levels. The zinc vapor passes through a flue into an adjacent column of carbon which is heated by the passage of the electric current. During the passage of the vapor down through the hot carbon, the carbon dioxide is supposed to be reduced to monoxide. The vapor then passes into a condenser, where most of the zinc is condensed as metal and some as blue powder. The furnace is operated continuously. The ore is pre-heated by gas to 900°C. before entering the electric furnace.

Except for a few statements, the information printed about the work done by Johnson does not clearly show the extent to which he has carried condensation without the formation of blue powder, but the use of a column of hot carbon to reduce the carbon dioxide in the vapor seems to have assisted in lowering the percentage of blue powder formed.

Present Status of Electric Zinc Smelting

From what has been said concerning the work at Trollhättan and the results of others, it is evident that the difficulty lies almost entirely in condensation of the zinc vapor to a metal rather than blue powder under the peculiar conditions of the electric furnace. The electric furnace, mechanically or electrically, presents no great difficulties to solve, because all of the troubles formerly experienced have been solved in the construction of large pig iron, steel, carbide, and ferro-alloy furnaces. The problem, then, is one of a metallurgical nature, and is caused by the different conditions and greater speed of smelting in the electric furnace than in the combustion retort. The opponents of the electric smelting of zinc ores, who as a rule appear to have no knowledge of the great development of the electric furnace itself in the treatment of other ores, often state that, while the retort is the weak part of the old system, so is the electrode the weak point of the electric method. Admitting that the retort is the weak part of the retort method, and judging from large scale electrometallurgical work on other ores, it cannot be conceded that the electrode is an exceptionally weak part of electric smelting. It is only fair to assume that the designer of an electric zinc furnace should stand upon the accumulated knowledge and take the results of others when the metallurgical problems of electric zinc smelting have been solved. One editorial writer in the *Engineering and Mining Journal* of December 14, 1912, goes so far as to say, in reference to retorts and electrodes, "nobody can say which will be the weaker." Actual figures would show that, rather than "nobody can say which will be the weaker," the retort at the present time is the weaker.

If the failure of the electric furnace in smelting zinc ores is not due to the electric furnace or the electrodes, what then is the metallurgical condition which causes condensation difficulties and has retarded the commercial application of the process? The difficulty is, of course, due to a difference in the smelting conditions of the electric furnace as com-

pared with the retort. Both physical and chemical conditions influence the formation of blue powder. Some powder forms under certain conditions of pressure and temperature. As to just what these conditions are has not yet been solved. It is a problem for the physical chemist.

By the use of electrodes of large cross-section it is probable that concentrated heating could be reduced so that, rather than a very high temperature at one place, there would be a uniform comparatively low temperature all over the charge. This was found to be the case in the smelting of iron ores both at Heroult, California, and Trollhättan. Or the current could possibly be distributed more evenly by flat electrodes of rectangular cross-section.

Complex Sulphide Ores

The electric furnace has a possible field in Western metallurgy at places where there are complex sulphide ores of lead, zinc, copper, gold, and silver. With the solution of the zinc condensation problem it is not unreasonable to suppose that ores of this class can be electrically smelted so as to get a fair recovery of the metals and at least the precious metals contained. Also, owing to the fact that practically as high a temperature as desired may be obtained in the electric furnace, it would be possible to smelt complex ores which have high gold and silver contents, but which are too low in base metals, such as lead and zinc, to make their recovery worth the additional expense of concentration. In the blast-furnace 10% of zinc in the charge causes sticky slags, and with a much higher percentage the operation of the furnace is very irregular and difficult. These slags could be fused readily in the electric furnace. In such a case, if the ore contained copper and zinc the ore could be charged into an electric blast-furnace using matte as a collecting agent for the gold and silver.

Gold and Silver Ores

In the smelting of gold-silver ores carrying no lead or copper, to form either a lead bullion or a copper matte, but containing iron sulphide, the electric furnace might be used in connection with an air-blast for oxidation of the iron sulphide, and an iron matte as a collecting agent for the gold and silver. The value of iron matte as a collecting agent is still largely a matter of personal opinion, but from the pyritic smelting which has been done with iron as a collecting agent, and from our experiments using iron matte in the electric furnace, it is evident that a fair recovery can be made in this way. As in the case of electric copper smelting, the electric furnace treatment of these ores is still in the speculative stage.

It seems probable that mines in isolated districts, where fuel is usually high and where the power operating the mine or mill is often hydro-electric power, could in many cases melt their cyanide precipitates more economically in electric furnaces than in combustion furnaces. The construction of a small Siemens type of furnace is simple and inexpensive. By operating the electric furnace when one of the units of the mill was down for repairs, or on the mine shift when little hoisting or drilling was being

done, no additional electrical installation would be necessary. This simply means that power which under ordinary conditions is wasted would thus be utilized.

Application of the Electric Furnace to the Smelting of Rare Metal Concentrates

By rare metals in this instance is meant such metals as chromium, tungsten, molybdenum, and vanadium. Chromium is not rare in the sense of the size of its ore deposits, but its metallurgy is so closely allied with the electric smelting of other more rare ores for the production of ferro-alloys that it may in this instance be considered as a rare metal.

The smelting of concentrates of tungsten, molybdenum, and vanadium ores for the production of either the metals or their ferro-alloys presents problems different in one marked respect from the smelting of copper, lead, or zinc ores, namely, the temperature necessary for completion of the reduction reaction is so high, or the melting point of the product is so great, that the operation could not be performed metallurgically or economically in a blast-furnace, reverberatory furnace, or a crucible. Tungsten is reduced from the trioxide at a temperature of $1500^{\circ}\text{C}.$, and vanadium from vanadate of iron or calcium at about the same temperature. The melting point of tungsten is $2800^{\circ}\text{C}.$, molybdenum $2000^{\circ}\text{C}.$, and vanadium $1750^{\circ}\text{C}.$ All of these temperatures are high compared with the reactions usually performed in combustion furnaces. Of course, the melting point of the ferro-alloy would not be as high as that of the pure metal, and becomes lower with increased percentage of iron.

The only rival of the electric furnace for high temperature metallurgy is the thermit reaction, which is more expensive. The electric furnace soon after its introduction into the manufacture of ferro-alloys rapidly superseded combustion furnaces for this work in all instances except the manufacture of ferro-manganese. It was found to be especially fitted for the smelting of rare metal ores to produce ferro-alloys because of the ease with which high temperatures were maintained.

The Manufacture of Ferro-Alloys in the Electric Furnace

The growth of the ferro-alloy industry in Europe has been rapid since 1899, but comparatively slow in the United States. There are about 25 plants engaged in the electric furnace manufacture of ferro-alloys in Europe, as compared with two plants making the alloys in the electric furnace in the United States. In addition to these there are three companies using methods other than electric furnace methods in the United States, and one electric furnace ferro-silicon plant in Canada.

There are several reasons why the growth of the ferro-alloy industry has been more slow in America than in Europe. Hydro-electric power is not so cheap here and not so favorably situated for the receipt of raw material and sale of product. The water-power sites cannot be developed as cheaply as many of the foreign sites, where the cost per kilowatt per year varies from \$10 to \$20, as compared with \$20 to \$40 in the United States.

A considerable proportion of the ferro-alloys used in the United States are imported, for, although there is a duty, local manufacturers are not able to supply the whole demand. About one-half of the ferro-manganese and ferro-silicon used in the United States is imported, as well as a large part of the ferro-tungsten. More ferro-titanium and ferro-vanadium are manufactured here than abroad. The ferro-chrome production just about supplies the domestic demand.

In Europe the industry of ferro-alloy manufacture in the electric furnace is in excellent condition commercially, with the demand for alloys steadily increasing. Because of the race between foreign countries in the building of large navies, there is great demand for ferro-chrome. The sale of ferro-alloys in Europe, especially ferro-silicon and ferro-chrome, is accomplished by the various plants combining in a syndicate, with each plant receiving a certain portion of the total market demand, according to the plant capacity.

Conclusion

In general, then, it may be said that, aside from the smelting of iron ores, the manufacture of aluminum and the production of ferro-alloys, the electric smelting of ores is still in the experimental stage. It will probably never replace existing processes where the conditions are favorable to the latter, except in so far as it may permit of the development of a process which may be more efficient than an existing process. For example, in the retort process of zinc smelting, a furnace temperature of from 1400 to $1500^{\circ}\text{C}.$ is required. This is the temperature on the outside of the retorts, whereas the actual temperature inside the retorts is from 100 to 200° less than this. Therefore, in this respect an electric furnace would offer the advantage that the full temperature of the furnace could be had just where it is needed; that is, where the work is to be done. For that reason, even though the electric current may cost more than coal for an equivalent heat value, the electric furnace may nevertheless be found more efficient and hence in the long run more economical than the combustion furnace, especially if the current can be used in the manner just indicated. However, as has been repeatedly stated, it does not seem to be necessary to consider the electric furnace as a competitor of the combustion furnace, but as affording the metallurgist a furnace which will enable him to treat certain ores and to work out certain processes in a more advantageous manner than it is possible to do in the combustion furnace, or to treat ores in certain districts where, owing to local conditions, it would not be commercially feasible to treat such ores.

Coal output of the Liege district of Belgium in 1912 amounted to 6,184,330 tons, an increase of 421,030 over that of the previous year. There were 74 active mines, and the price of coal averaged \$3.30 per ton. Employees numbered 37,878, who averaged \$289 per year in wages. There were 21 blast-furnaces in operation, yielding 973,840 tons of pig iron worth \$13.70 per ton. Two mills produced 20,100 tons of lead, and silver valued at \$947,273.

Progress at the Hidden Creek Copper Mines

*The work finished during the past year in connection with the development of the Company's Hidden Creek mine, at Anyox, consisted of 8857 linear feet of raising, sinking, driving, and cross-cutting, with 18,342½ ft. of diamond-drilling. This work was done on the 150, 230, 385, 530, 630, and 700-ft. levels. In addition to this 3090 cu. yd. of rock was removed underground in the widening of the 150-ft. level at the ore chutes, and in the excavation of the crusher room on the 230-ft. level, according to the report of O. B. Smith, superintendent of mines. The total development work now done at the mine is as follows:

Class of work.	Feet.
Surface trenching	2,255
Driving and cross-cutting	13,905
Sinking and raising	2,946
Diamond-drilling (72 holes)	37,518

The above work has developed 7,759,550 tons of 2.2% copper ore, containing 20c. per ton in gold and silver. The bulk of the estimated ore lies above the 385-ft. level, only 394,100 tons below this level being included. There are huge quantities of 0.5 to 0.7% ore surrounding the higher-grade ore of No. 2 orebody, but are not figured in the total.

All work on the 150 and 230-ft. levels is at present in connection with the loading, crushing, and storage arrangements. The 150-ft. adit was driven 416 ft. and the raises driven to the crusher level or 230 feet. The raises give a storage of 2500 tons of crushed ore ready to be loaded on the smelter trains. On the 230-ft. level the crusher room was excavated and three raises, which have a total capacity of 2500 tons, driven to the surface. The 385-ft. adit track has been continued 1500 ft. from the portal so that cars on this level can dump directly into any one of these raises. This work is now practically completed.

Drifts were driven along the No. 1 orebody to the north and south of the main adit on the 385-ft. level. A raise was driven to No. 20 drift of the 530-ft. level to serve as an ore-pocket* for ore from the latter level. The adit was continued toward No. 2 orebody and has reached a length of 1678 feet. The adit is now in low-grade rock and should be expected to cut No. 2 main orebody in a short distance. Near its end another raise was driven to No. 40 drift of the 530-ft. level for a pocket for the ore of No. 2 orebody.

The ore in No. 1 orebody on the 530-ft. level north of the main adit was blocked out by drifts and cross-cuts. The blocking out of the ore in No. 2 orebody was continued in No. 70, 80, and 90 drifts and No. 40A cross-cut. On this level 35 raises were started, and timber for the chutes placed.

Drifts were driven in No. 2 orebody on the 630 and 700-ft. levels to the north and south of the main adits.

The mine is now ready to handle the 2000 tons per day needed to supply the smelter. The result of the drilling and underground development during the

past year has been particularly gratifying, and the mine is in excellent condition.

Regarding the 2000-ton smelter being erected, of which the accompanying half-tone shows some of the steel work, the assistant general manager, F. M. Sylvester, writing on September 7, says:

"Viewing the progress of the construction work on the new plant, it appears to me that the men in charge are doing remarkably well and that good progress is being made, especially when due consideration is given to the excessive cost of labor and material, the rains, and generally adverse conditions under which they are working, and that, except for unusual contingencies happening, to delay, all will be ready to try out the plant at least by the

NEW SMELTING PLANT, ONE BLAST-FURNACE IN CENTRE.

first of the year. It is not likely that all of the work in connection with building the plant will be completed, but barring unusual delays, all of the essential construction should be completed and ready for operation, as at least 90% of the machinery equipment is on the ground, the foundations are completed, so that the installation of this machinery will begin at once; in fact, a start has been made on one of the furnaces now. In view of the status of the work at present, I therefore feel warranted in saying that the plant will be ready to begin operations by the first of the coming year.

Ores of tungsten and tin have been discovered practically all over the Tavoy and Mergui districts of Burma, India, and a large number of concessions are being worked. Wolframite is the main object of exploitation, cassiterite being a sort of by-product, although at times the tin ore forms a larger percentage of the alluvial deposits than the wolframite. It is practically impossible at this stage of development to give any figures showing what percentage of wolframite or cassiterite occurs in the lodes, as very little lode mining has been done, but judging from the abundant alluvial deposits scattered over the hillsides near the lodes and by the appearance of the lodes themselves, there is ample justification for prospecting some of the lodes by adits. It is said that work of this nature is being carried out on several concessions. Natives earn up to 48c. per day. The total cost of producing and delivering a ton of 68% ore in England is \$313.76, and when the price is \$7.30 per unit of tungstic trioxide, there is a profit of \$180 per ton. —Daily Consular Report.

*Abstract from annual report of the Granby Consolidated Mining, Smelting & Power Co., Limited.

Pig-iron output in September was 2,505,927 tons.

The One-Man Drill

*It is claimed by the Western Federation of Miners and its members that the one-man drill, so called, has placed a burden upon the miners in the copper mines of Michigan which is not commensurate with the wages paid. Drilling originally was done by hand. As the mining industry developed, a power drill was introduced which was operated by two men. The introduction of the first power drill met with the same resistance which is now being offered to the one-man drill.

Increase of Cost with Depth

It may be stated generally that in the Lake Superior copper district the average copper content of the rock decreases with depth. This has been the history of the district, and the cost of mining increases proportionately with depth. The Michigan copper mines are operating on rock containing lower copper content than the other copper-mining districts of the United States, and the Michigan copper mines are operating at greater depth, and consequently at greater cost, than the other copper mines of the United States. In order to compete, it is absolutely imperative that the mines of Michigan should be operated with the closest economy. The operators in Michigan have attempted to practise their greatest economy in the way of improved machinery and equipment, and the greatest step that has been made in this direction in recent years is the installation of the one-man drill. The standpoint of the operators in regard to the one-man drill cannot be given any more clearly than in quoting from a statement made by the superintendent of one of the mines, as follows:

"The necessity for further close economy in the operation of our mine forced us to go into the market for a more efficient drilling machine, and, if possible, a machine that could be operated with one man as compared with two, which was standard practice. After about 18 months of experimenting the present machine was adopted. Our intention was to divide the benefits accruing to us from the use of the one-man machine with the men; this benefit to take the form of higher wages to machine operators (called miners). That this plan has been carried out is shown by the following table, which shows the increase in wages to the men operating one-man drills over wages made when operating two-men drills.

COMPARATIVE STATISTICS ON ONE-MAN DRILL AND TWO-MAN DRILL, CALUMET & HECLA AND SUBSIDIARY MINES, FOR THE YEAR ENDED DECEMBER 31, 1912.

	2-man drill.	1-man drill.
Shifts	350,012	54,758
Labor cost	\$1,024,801.84	\$ 193,935.81
Supplies	291,526.14	94,058.24
Total	1,316,327.98	287,994.05
Average wage per shift.....	2.83	3.34

"The miner's wages largely depend upon the efficiency of the man, as our work is all on the bonus system, and is so arranged that increased efficiency is of mutual benefit to the employer and the em-

ployee. We have a fixed contract which is not cut as the efficiency of the employee increases. It is also one of our rules that in case a man does not make what is called a fair rate, he is paid off at a rate of not less than \$65 per month, but this ruling affects a very small portion of our employees. In fact, for the month of June this year, it was not necessary to use this minimum wage for a single employee. The one-man drill has resulted in a decided increase in efficiency, which, with further experience, will increase and will result in not only lower costs, but in higher wages to the men. What is more, the drill is popular with the good miners and any sentiment against it is made from without. Any attempt to return to the two-man drill would be a backward step in industrial progress and would work untold hardship to this district in its competition with other copper-producing districts. It is as little to be thought of as the elimination of any other labor-saving device. If copper mining in Michigan is to be a progressive and permanent institution, our methods must be shaped anew to be able to work deposits of a still lower grade than have been worked up to the present time, and the one-man drill and the further possible increase in the efficiency along this line is the most important step now before us."

The committee talked to a number of miners who were operating the one-man drill, and in no case found any specific objection to its use. In a few instances the men claimed that it was difficult to set up in some places, but the committee found that it is a practice among the miners for one man to help another whenever necessary. The one-man drill operators interviewed invariably admitted that they are making more money on the one-man drill than they were on the two-man drill, and not in a single instance did the committee find a man that would give up his one-man drill to go back to the two-man drill. The committee found in some cases men who said that two men should be on the drill, but when requested for their reasons and asked of what assistance the second man would be in operating the drill, they were unable to give any except that the assistance would be given to set up the drill in the morning and to take it out of the way before blasting. The committee, on one of its trips underground, saw one man set up his drill in nine minutes, but from what the committee has been able to ascertain, the average time required by the miners to make their places of work safe by barring down loose rock, preparing the place for the drill, and setting up the drill seems to be about one and one-half hours.

Influence on Labor

The claim has also been made to the committee that a great many men would be thrown out of work by the adoption of this drill, but mining men and engineers in this particular district claim that the installation of this one-man drill will permit mining companies to work poorer ground than has ever before been handled in the district, and that instead of throwing miners out of employment, it will create a demand for more miners.

On its trips underground, the committee took oc-

*From a report upon the strike situation by the Copper Country Commercial Club.

casation to ascertain whether or not the mining companies were operating in accordance with the law passed at the recent session of the Legislature in reference to the one-man drill, namely, the act providing that men operating these machines should not be stationed more than 150 ft. from the place where other employees were at work, and the committee found, as a matter of fact, that the mining companies generally were operating in accordance with this act.

The committee made some inquiry as to how the one-man drill is received by miners in other copper districts, especially the Bisbee district of Arizona, and quotes from a letter received by it under date of September 29, 1913, from one of the mining engineers of the property of the Calumet & Arizona mine:

"The Company has in operation at the present time 100 one-man drills, which is 90% of the total number of drills now on development work. Sixty-five of these drills were purchased during the last four months. The miners have no complaints to make relative to these drills, and in the majority of cases prefer these to any larger drill. The one-man drill will no doubt replace all other larger drills in the near future. I cannot understand why the Michigan miners should object to the drill when the Bisbee miners can find no fault whatever."

Deep Mining in Australia

According to the annual report of the Victorian Mines Department, there were 15 mines with shafts over 3000 ft. in depth at Bendigo, and several over 2000 ft. deep on other goldfields. Those at Bendigo were: Victoria Quartz Reef, 4614 ft.; New Chum Railway, 4318; Lazarus New Chum, 3682; New Chum & Victoria, 3579; North Johnson's, 3498; Great Extended Hustler's, 3493; Carlisle, 3460; Lansell's 180, 3365; Clarence United, 3310; Ironbark, 3250; Victoria Consols, 3114; New Chum Consolidated, 3099; Eureka Extended, 3060; Princess Dagmar, 3020; and Johnson's Reef No. 2, 3020 feet.

No fewer than 53 shafts at Bendigo are over 2000 ft. deep. The following were the deepest mines on some of the other principal goldfields: Long Tunnel, Walhalla (incline), 4051 ft.; Long Tunnel, Walhalla (vertical), 3450; Magdala, Stawell, 2425; South German, Maldon, 2225; Lord Nelson, St. Arnaud, 2405; and Jubilee, Searsdale, 2014 feet.

Costs at the El Oro mine, Mexico, where 253,434 tons of ore and 180,274 tons of old tailing were treated during the year ended June 30, 1913, were as follows:

	Per ton mined.	Per ton treated.
Mining	\$2.08	\$1.22
Development	1.42	0.83
Milling		0.18
Cyaniding		0.78
Water-supply		0.02
General expense		0.20
Taxes		0.21
Total		\$3.44

Idle-car surplus at October 1 was 10,374 cars.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Water in Veins

The Editor:

Sir—My attention, as a reviewer, has been called to that most excellent summary of existing knowledge concerning secondary enrichment contained in Bulletin 529, U. S. Geological Survey. This is the essay on 'The Enrichment of Sulphide Ores,' by William Harvey Emmons. Nothing could be more timely, and nothing could so well emphasize the practical application of geology to mining or of science to mineral discovery. My cordial appreciation of the excellence of Mr. Emmons' presentation of the subject is expressed elsewhere, in *The Mining Magazine* for October; in this trespass on your space I desire to present a more personal, and yet, I trust, not useless aspect of the matter. In outlining the main facts known about the distribution of water in the upper parts of lodes, Mr. Emmons refers more than once to Messrs. J. F. Kemp and J. W. Finch as having emphasized "the shallowness of the zone of meteoric circulation." This is true, but not completely true. Readers of this journal will recollect more than one effort of mine to "emphasize" this phase of the subject. In the course of a paper entitled 'The Cripple Creek Volcano,' written in 1899 and published in February 1900, I referred to the dryness of deep mines, in the following words: "Experience goes to show that the water encountered in mines is the drainage from the surface. Deep mines are usually dry ones. I may instance the deepest metal-mines, the Calumet-Hecla and the Tamarack, in the Lake Superior region, and the 180, New Chum-Victoria, and neighboring shafts at Bendigo, in Australia." (*Trans. Amer. Inst. Min. Eng.*, Vol. XXX, page 377).

The idea was elaborated in an article entitled 'Water in Veins—a theory' (*Engineering & Mining Journal*, March 14, 1903), in which was brought forward the idea of a water zone, as against the indefinite saturation in depth currently accepted in geological literature. The water-level had been recognized by the miner long before the geologist wrote concerning it; what I did was to point to the fact that there was also a lower limit. This is much more irregular than the upper one, but no less recognizable. Again, in the *Mining and Scientific Press* of June 27, 1908, in discussing a paper by my friend Professor Kemp on 'Waters Meteoric and Magmatic' I brought the idea forward, with diagrams illustrating the conditions supposed to obtain in that outer portion of the earth penetrated by mine workings. Numerous facts concerning the deep mines and the dry condition of their bottom workings were adduced. I returned to the charge in 'Geology Applied to Mining.' See *Mining and Scientific Press*, April 2, 1910, page 281. Finally, in discussing 'The Persistence of Ores in Depth' in the *Mining and Scientific Press* of August 24, 1912, I

laid stress on the importance of recognizing this water zone as a factor in ore deposition. Mr. Emmons speaks of 'emphasis' being placed on "the shallowness of the zone of meteoric circulation." May I claim to have been emphatic?

You, Mr. Editor, will appreciate, I trust, that this is not a plaint for the recognition of a writer, but a demand for the recognition of a geological idea. That sundry geologists, most of them personal friends, should have overlooked the contributions of one whom they probably regard as an amateur, because he was an engineer and is now a journalist, is not surprising; but that keen students of the subject, and authoritative expositors of it, should persistently ignore an explanation of one of the fundamental factors in ore deposition, is anomalous. If the 'water zone' idea as suggested and explained by me is fallacious, it ought to be smashed, lest it mislead the few who may take my writings seriously; if the idea is sound, it should be acknowledged and utilized by those who are building a comprehensive theory of ore deposition. In short, in the conventional terms of social intercourse, I say to my friends: R.S.V.P.

T. A. RICKARD.

Mining Law and the Prospector

The Editor:

Sir—In the *Press* of August 12, 1911, there appears an article by G. O. Smith on the revision of the mining laws from which it seems that a man without title or many ciphers to his worldly accumulations is not worthy to pass judgment on revision. Let those gentlemen, who argue this, land in a new mining district with their hard-earned life's savings, ambition, and no fear of work, put in ten or twenty years and those savings, and then they can talk revision of the laws from a prospector's point of view. I would like to see some editor stick up for the rights of the forerunner of the mining industry, the original discoverers, those pioneers who endure the hardship and isolation. I have spent forty years of my life in this district, thirteen years at hard work, and have some good quartz claims. Mr. Smith would have the Government relieve me for not developing these claims more rapidly. Some people seem to fear that the world will come to an end before everything is developed. As to the apex law, my vein dips something like 75 degrees; why should not I or any man get the benefit of his own discovery and perseverance? Mr. Smith says not; that it has caused lawsuits (retarding development again); but anything can cause a lawsuit. It is the courts that need revising, in my estimation, that the poor may get just and equal rights. Our mining laws are easily understood by ordinary intelligence, and I am thankful that I live and lived in a period when the mining laws give the poor such liberal inducement; it's like a touch from the big-hearted and far-seeing Lincoln. The best words President Taft said while in the White House were: "Our mining laws are good enough." For surely our mining laws are the best in the world for the prospector and producer, with no license, gold commissioner,

or government to impose on him. I would like to hear of some prospector who can find fault with the laws. Fault is usually found by some who want more fancy jobs created. There are few experts, mining men, and I fear a very few editors who have prospected and paid their own way. I have read many articles by those wishing a revision and more complicated laws, and it would seem the 'big interests' may want laws more to their advantage and in some way to cut the little fellows out entirely.

ARCHIE HUNTOON.

Galena, Washington, May 19.

[That the prospector's viewpoint is an important one goes without saying, and we take pleasure in printing this note from one who by actual experience has come to know the significance of our mining law as applied to the prospector. However, we cannot agree with the inference that any contemplated changes in the mining law will work to the detriment of the prospector. On the contrary, it is the purpose of reform to aid and abet both prospecting and the prospector, whether he be the lone pioneer of the industry who goes forth into the wilderness in search of gold or the prospecting corps of a large corporation.—EDITOR.]

Transportation Problems in Bolivia

The Editor:

Sir—In reply to the letter of Lester W. Strauss, in the *Press* of October 4, 1913, I beg to state that Mr. Strauss is right in saying that the Peruvian oilfields near Lake Titicaca have been abandoned, as I find this in the records of the *Boletins de la Sociedad de Ingenieros*. There are no coal and oil lands in Bolivia. According to the *Monografia de la Industria Minera* in Bolivia, by Pedro Aniceto Blanco, the leasehold per hectare of mineral land is 2 Bolivianos (80c. U. S. cy.) per half year. The narrow gage railroad (of 30 in.) was built by the Huanchaca company from Antofagasta to Pulocayo and then continued from Uyuni to Oruro. From there the gage was changed to 1 metre and maintained for all future railways and is called in Bolivia—the Bolivian Standard gage. About 'Carana,' that unfortunately was the engravers' blunder, changing Charana to Carana. The La Paz-Arica line runs from Viachi to Charana on the frontier of Chile, and there is also a line projected from Oruro to Charana. Corocoro has also been misplaced and ought to have been on the Arica line, between Viachi and Charana, as Mr. Strauss mentions.

G. W. WEPFER.

Berkeley, California, October 6.

Indian Gold Production

The group of mines at Kolar, State of Mysore, yielded as follows in September:

	Tons.	Ounces.
Balaghat	3,550	1,419
Champion Reef	18,332	11,411
Hutti (Nizam's)	2,225	1,820
Mysore	24,691	18,881
North Anantapur	2,000	918
Nundydroog	7,500	6,662
Ooregum	12,901	8,028

LONDON

INTERESTING TESTS BETWEEN THE ORDINARY GRAVITY AND NISSEN TYPE OF STAMPS AT CORNISH MINES.—THE ANANTAPUR GOLDFIELD OF INDIA.

In making comparisons between the efficiencies of various methods of treating ore, it is seldom that competitive experiments are made side by side on the same ore. This is particularly the case in connection with comminution. An engineer will praise the Chilean mill for its work done on certain gold ores and allege that the results are better than from ordinary stamps; but as he did not test the two concurrently, or give exact detail of the constitution and physical characteristics of the ore, his statistics fail to convince. The method pursued by Edward S. King, in connection with the crushing of Cornish tin ores, affords a pleasing contrast. The problem in tin-dressing is to form as

NISSEN AND ORDINARY STAMPS.

little slime as possible, for it is next to impossible to concentrate this class of material. It has hitherto been held by Cornish managers that the best way to prevent sliming is to use as light a stamp as is otherwise advisable, and in the modern installations of stamps the limit of 1050 lb. has rarely been exceeded. Mr. King, however, desired to pursue investigations on another tack, and sought to test a machine designed specially with the object of hastening the discharge from the mortar-box. He accordingly has installed two Nissen stamps. Many Cornish engineers were aghast at the idea of using a stamp weighing 2000 lb. on tin ore, but Mr. King admitted the logic of Peter Nissen, when claiming the greatly increased screen-area and direct splash of the pulp on the screen as potent factors in reducing the formation of slime. In order that the tests should be conclusive, a 5-stamp mill containing ordinary stamps of 1050 lb. each has been erected by the side of the Nissen stamps, and the two sets are to be fed from the same bins. The latter stamps have been at work for some time, but the former are only now being completed. Comparative tests have however been made between the Nissens, which, I ought to say, are at the Carn Brea mine, and the standard stamps at South Crofty, the mine immediately adjoining. Josiah Paull, the manager of the South Crofty, being desirous of testing the two types before deciding on plants to be erected at the Tresavean mines near Redruth, for which he

is consulting engineer, sent shipments of both ores to the Nissens at Carn Brea and to the South Crofty plant. The result was that, with the Nissens only 33% of minus 200 mesh was produced, as compared with 39% with the ordinary stamps. Other features of the Nissen, such as capacity and power required, satisfied Mr. Paull, and he decided to recommend their adoption at Tresavean. He has since then recommended them for the Garlidna, an old mine that is being opened in the Wendron district. At the Carn Brea mine other novelties are to be introduced in connection with tin-dressing. One is the use of the Card table, a machine that has given satisfaction at the Mount Bischoff tin mine in Tasmania, and the other is the adoption of the Cobbe-Middleton pan for regrinding middling. The latter is also a machine that was developed in Australia. It will be remembered that at the Geevor mine, near Land's End, Deister tables and Hardinge regrinding mills have been installed. The results of the two systems will be followed with interest.

The Anantapur goldfield in India has at last provided a return, if only a small one, on the capital outlaid. The district was first brought to the notice of the British public in 1906, when a company called the Anantapur Gold Field Limited was floated by John Taylor & Sons. The property acquired consisted of old workings of a similar nature to those at Kolar, in the Mysore State, 200 miles to the south. The Kolar goldfield did not give immediate results, and for two or three years there was a doubt whether to continue or not. Subsequent history during the past twenty-five years is sufficient evidence that perseverance has in this case provided a reward. The results achieved at the Anantapur deposits have been fairly promising, though progress has been slow and no large body of ore has so far been disclosed. Experience in connection with the Kolar district has kept shareholders in buoyant mood, though it must be said that the other Indian enterprise of John Taylor & Sons, outside Kolar, that is to say at Dharwar, in the Bombay Presidency, might have depressed their spirits, seeing that the venture has been an entire failure and has been suspended. After a few years' work, Anantapur deposits were proved to be sufficiently promising to warrant development on a larger scale. One block was sold to a new company called the North Anantapur Gold Mines Limited, and another was taken up by the Nundydroog company, one of the Kolar group, to be subsequently formed as the Jibuttil Gold Mines Limited. The North Anantapur has now issued a report for the year ended June 30 last, announcing a small profit. It should be said that the North Anantapur company was formed in 1908, and that in 1911 additional capital was required for development and completing the payment for the plant. The present issued capital of the company is £74,268 in £1 ordinary shares and £20,000 in 20% preference shares, the latter being issued in 1911 to provide the additional funds. During the year ended June 30 last, 22,827 tons of ore yielded gold worth £35,867, and the profit was sufficient to provide £2,000 for the owners of the preference shares, being at the rate of 10%. Development has continued to maintain the reserve of ore, the figure on June 30 being 44,000 tons, as compared with 42,000 tons a year ago. It is stated that the main ore-shoot, out of many, is longer at depth, being 335 feet long at 550 ft., as compared with 282 ft. at 450 ft. and 135 ft. at 300 ft. depth. A winze below the 550-ft. level is even more promising, as the lode is proved for the 70 ft. of depth so far sunk to be 5½ ft. wide and to assay 2½ oz. gold per ton. Shareholders are enthusiastically living in hopes that development in depth will prove as profitable at Anantapur as at Kolar.

The interim report of the Rio Tinto Copper Co., operating the largest copper and sulphur mine in Spain, for the six months ended June 30, states that mining in the open-cuts and underground, has been of a normal character. The copper output was a trifle lower than usual. A dividend of 2s.6d. per share was paid on the 5% preference shares, and one of 40s. per share on the ordinary shares.

NEW YORK

THE MEXICAN SITUATION.—HOLLINGER RESERVE MINE.—FEDERAL MINING & SMELTING CO.'S ANNUAL MEETING, AND ANSWERS TO CHARGES BROUGHT AGAINST THE DIRECTORS.

Mining circles here have had no great sensations except such as are evoked by the precarious situation in Mexico. The general feeling seems to be a determination to support the Government in any difference it may have with foreign nations. The utterances ascribed to Sir Lionel Carden have been repeatedly denied. All sorts of views are current, one that European nations are about to force the hand of the United States and bring about intervention. It has just been announced from Washington that a new policy is being framed for the solution of Mexico's difficulties, which will demand the elimination of Huerta from Mexican politics. However, as the situation is not solely dependent upon one man, but rather a diseased condition of the greater part of the country, no immediate solution is anticipated.

The Lewisohn interests (General Development Co.) have taken a year's option on the Hollinger Reserve property at Porcupine, Ontario, under the terms of which they agree to perform a stipulated amount of work monthly, and in return receive treasury stock of the Hollinger Reserve Mines, Ltd. At the end of the year the General Development Co. will practically control the mine. Work at present is confined to sinking the shaft to the 300-ft. level. The citizens of Porcupine are jubilant over the advent of this strong group in the district, and the, in many respects, disappointing results of exploration to the present are forgotten in the hopes for the future.

The annual meeting of the Federal Mining & Smelting Co. was held in New York on October 20, results of the past year being given in the general mining news of this issue. A. M. Strode, of Mullan, Idaho, near where the mines are situated, asked questions relative to the New York office of the Company; how often the books are audited; where the funds are kept; and whether a secret fund for political purposes is maintained in Idaho. The chairman of directors, Francis K. Brownell, stated that the New York office cost about \$820 per year; the books are audited monthly in New York and yearly at Wallace, Idaho; funds are kept in New York, \$25,000 at Wallace, and \$25,000 at Spokane, Washington; no political fund is kept, but admitted that the Company holds an interest in the *Press Times* at Wallace, with the Bunker Hill & Sullivan and other companies in the district. There was also a denial that the Federal company was affiliated with the United Stores Co., compelling employees to purchase stores from that concern. The Federal company also owns 50% of the stock of the Green Hill Cleveland company and has received \$245,000 in dividends therefrom plus \$90,000 more, there being about \$125,000 in this Company's treasury. Its operating profit during the past year was nearly \$500,000, and the contract for selling the ores was similar to that made for the ores from the Federal mines which are sold to the American Smelting & Refining Co. This was in reply to a charge that Messrs. Day and Brownell were acting more for the latter Company than the Federal. Sidney Norman, representing the minority common stockholders of the Federal company in New York, who are suing to have the selling contract with the American Smelting & Refining Co. annulled, was also present, and asked several questions regarding the prices received by the Company for its products during the year. Among other things, he tried unsuccessfully to ascertain the exact price received for the Company's lead during the past twelve months. He had computed roughly that under the contract the Federal had lost about \$347,000. In reply, Mr. Brownell stated that even if Mr. Norman's statement and figures were true, which was not admitted, there would be no more cause for abrogating the smelting contract than if the reverse had happened; that is, if the contract was made so favorable to the Federal, that the smelting company might desire to have it annulled. He also stated that any engineer representing the minority holders would be permitted to inspect the property.

PHILADELPHIA

DETAILS OF MEETING OF THE AMERICAN MINING CONGRESS.

The American Mining Congress held its annual session at Philadelphia from October 20 to 24, inclusive. The headquarters for the meeting were at the Bellevue-Stratford hotel. The session opened on Tuesday afternoon by an address of welcome by the representative of the Mayor of Philadelphia to which D. W. Brunton, the president of the Congress, made an appropriate response, and was followed by B. F. Millard for Alaska, W. H. Fluker for Georgia, C. J. Norwood for Kentucky, J. R. Burton for New York, H. N. Lawrie for Oregon, Isadore Broman for Texas, Niell Robinson for West Virginia, and Joseph M. Carey, ex-governor of that state, for Wyoming. At the evening session the president delivered a thoughtful address which, unfortunately, there were but few present to hear. The poor attendance at all the sessions of the Congress was doubtless due to the fact that E. T. Connor, who had been most effective in arranging for the Congress, was seriously ill in the hospital. In addition the meeting was naturally considered to centre around the coal-mining industry, and the lack of concerted action in that industry does not make for enthusiasm. The morning session on Tuesday was devoted to a discussion of taxation of mining property, the principal papers being by R. V. Norris, H. M. Chance, and D. L. Webb; B. W. Vallat and J. W. Malcolmson taking part in the ensuing discussion. The situation in Pennsylvania is complicated by the fact that the state constitution provides only for uniform taxation of all property on an assessed valuation, so that the problem becomes really a discussion of the valuation of mining property for the purpose of taxation. The difficulties of arriving at such a valuation were pointed out, and Mr. Malcolmson pointed out that taxation in South Africa is on the basis of net profit, while in Mexico it is based on the gross output. The drawbacks of each of these bases were pointed out, and Mr. Malcolmson urged that a proper and equitable basis would take all three into account. The morning session was concluded by a paper on uniform requirements for official mine reports by S. A. Taylor, who pointed out that the various reports called for by the various statistical bureaus of the Government involved much unnecessary labor and by slight readjustment essentially the same information could be furnished at much less expense. In the afternoon the delegates and their friends were taken for an excursion on the Delaware river, in order to see the shipbuilding yards and other points of local interest, concluding with a visit to the League Island Navy Yard, where the delegates were allowed to inspect the battleship *Minnesota*. The evening session consisted of an address on mine-rescue and recovery work, by J. W. Paul, which was discussed by George S. Rice. R. W. Gunnell talked on the use and abuse of explosives, and the evening was concluded by a description of the coal resources of Alaska by W. R. Crane. On Wednesday resolutions were introduced, the committee on Alaska affairs made its report, and an excellent paper on 'The Industrial Corporation and Scientific Research' was presented by D. B. Rushmore. In the afternoon E. B. Kirby presented the report of the committee on revision of the mining law, the report essentially agreeing with that of the similar committee of the Mining and Metallurgical Society. This was followed by the 'Plain Talk' by George Otis Smith, Director of the U. S. Geological Survey, as printed in the *Mining and Scientific Press* last week. A discussion of the effect of federal administration of the public lands on the mining industry by J. F. Shafroth, senator from Colorado, followed. It was directed principally against Government ownership of 9,425,000 acres of coal lands in Colorado, valued, he said, at from \$500,000,000 to \$1,000,000,000. Mr. Shafroth urged the sale of these lands to citizens or to corporations for \$400 per acre. In this manner, he said, they would be developed, and would produce enough coal to last the entire world 300 years. The evening session was devoted to the address by C. R. Van Hise on 'Big Business and Industrial Prosperity,' of which a summary will be printed next week. Mr. Van Hise took the attitude of the best informed thinkers in concluding that the collective

good of the public is not, as at first supposed, to be secured by forcing the most vicious form of individualism in unrestricted competition, but is rather to be secured by collective action for the common good. Thursday's session was opened by an interesting talk on the mining exhibit at the Panama-Pacific Exposition by C. E. van Barneveld, its director. E. W. Parker followed with a highly important paper on the cost of coal production, in which the fact that coal mines at present generally pay less than 2% on the investment, due to unrestricted competition and unequal legislation, was brought out. A paper by J. W. Boileau on 'What is the Matter with the Coal Industry?' was read, and A. J. Moorshead, in the following discussion, laid the blame upon the operators for their selfishness and lack of coöperation. Those who have attended the past sessions of the Mining Congress must have marveled to hear a speaker advocating federal regulation of the mining industry to secure 'a common law for a common industry for the common good,' and be loudly applauded. It is most significant that, in many fields of mining, operators are coming to feel their interests can be best secured by federal rather than state regulation. The afternoon session was devoted to a paper on gold-mining in Georgia, by W. H. Fluker; a most important paper on the radium situation in this country, by C. L. Parsons, of the Bureau of Mines; and an equally important address by M. D. Foster, chairman of the House Committee on Mines and Mining. In the evening a smoker and vaudeville entertainment, followed by a supper, was given. This brought out the only large attendance of the session, and is a sad commentary on the interest of those present in Philadelphia, since the papers presented unquestionably surpassed those at any preceding Congress. The morning session on Friday was given up to report of the ways and means committee, which brought out the discouraging fact that there are only about 450 members of the Congress who pay yearly dues, the rest of the attendance being made up of delegates, and that the organization owes the salary of the secretary, J. F. Callbreath, for a long period in arrears. The committee on standardization of electrical equipment in coal mines made a brief report, the principal address of the morning being by William B. Wilson, Secretary of the Department of Labor, who discussed on a high plane arbitration as a factor in the mining industry. His remarks met with vigorous opposition by some of those present. The afternoon session was devoted to the consideration of resolutions, of which there were too many for even a summary. Those on blacklisting and on monopoly in the mining and smelting field attracted most attention. The session concluded on Friday afternoon. A resolution offered by Sidney Norman, of Washington, which refers to the "dishonest operations of the financially powerful" as a great menace to the mining industry, was adopted. Through this resolution the Congress went on record as favoring the institution of universal state laws that will provide protection to minority stockholders by making directors more definitely responsible for their welfare and constituting infraction of such laws a felony, punishable by fine and imprisonment. It pledges itself to support legislation necessary to put such laws into effect, and suggests that the Department of Justice investigate "scandals recently disclosed regarding securities listed on the New York Stock Exchange," to the end that responsibility may be properly placed and the offender brought to justice.

VICTORIA, BRITISH COLUMBIA

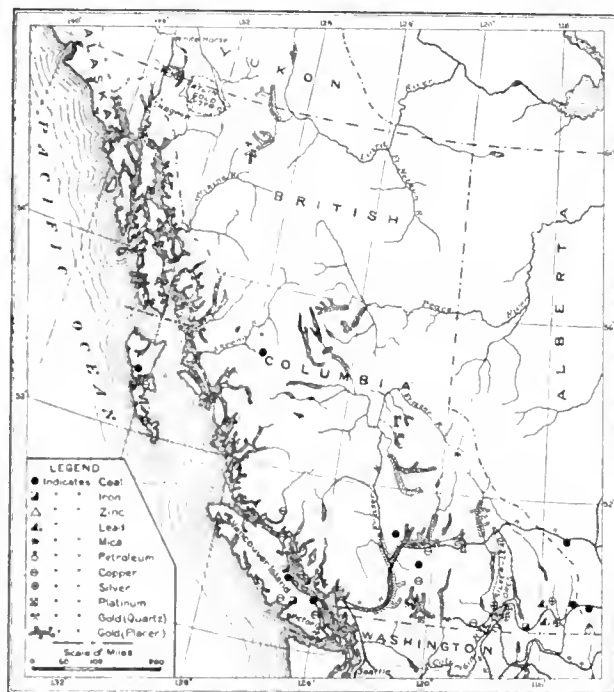

PLACER MINING AT SIBOLLA CREEK, RESULTS AND PROSPECTS.

Information relative to what is known as Sibolla creek, in the southwestern part of the Skeena district of British Columbia, has been received from Telkwa, which is situated at the junction of the Telkwa and Bulkley rivers, the latter being a tributary of Skeena river, into which it flows near Hazelton. Sibolla creek is about 120 miles southwest of Telkwa, and west of the lake country in which are Francois, Ootsa, Tahtsa, and numerous other lakes. The Coast range forms, in that part of its length, the divide between the lake country on the east and the head of Gardner canal on the west. The newly reported placer-gold field can be

reached by (1) Gardner canal, thence eastward up Kemano river and over the Coast range, from the west (though as yet this route has been little used) (2) trail south from Telkwa; or (3) west from the route of the Grand Trunk Pacific railway line at Fraser lake and thence by Francois and Ootsa lakes.

A report on the new district contains the following:

Of ten days spent at the Sibolla Creek placer field, three were occupied in sampling the gravel above Discovery claim, on the creek, and this resulted in finding colors in only one pan out of four. No coarse gold was shown. Below Discovery, at the first three claims, the result was similar, and after that, to No. 19 below, the colors became more numerous, and not more than one-quarter of the total panning was barren. A shaft was being sunk at that time by S. White, I. McCulley, Dave Mackenzie, Billy George, and Louis Koitsa, in an effort to reach bedrock, and after 12 ft. of a 6 by 6-ft. shaft had been sunk, a windlass erected, and the hole timbered, the water flowed in so great volume that work on all the creek claims was stopped. Attention was

MAP OF BRITISH COLUMBIA.

then given to the bench claim of Leo McLaughlin and partner, on the north limit of No. 3 below Discovery, but at the time of writing, bedrock had not been reached. Colors were consistently present all the way down the shaft, which was then 15 ft. deep, timbered, and equipped with a windlass. Prior to leaving the field, most of the prospectors going out turned over all their spare supplies to those two men, who then had provisions for two months. The only other party on the ground properly equipped is that of George Barrett and Joseph Bussinger, who has a good outfit, including a rocker, and provisions for four months. They are staked on the bench and should reach bedrock in the big flat without being seriously impeded by water.

The bench north of Sibolla creek had all been staked, but as far as could be seen, no effective development had been done, except an 8-ft. hole sunk on the Newsboy claim, in which colors were present after the first three feet. The wash there is deep and at the bottom of the hole the conglomerate gravel, slightly cemented, is moist and full of air spaces; 'pay' is not likely to be found until a strata more dense and less coarse shall have been reached. On the bench due west of the camp some promising ground was seen; this is marked with dry water courses and is sedimentary in character. The gravel is fine and heavily cemented, but no 'pay' was found, though colors were fairly plentiful, with a large proportion of white iron and some black sand. A dozen claims had been staked on that ground.

Contrary to the first report, no contact of slate and porphyry was seen, but shale or coarse slate runs parallel with

the porphyry along the range and dips into it at an acute angle. The large rounded boulders so numerous in the wash are chiefly gray or blue granite, while rose quartz is plentiful in the gravel, with an occasional small specimen of gold in some of the larger pieces. The field shows no sign of having been an ocean beach but rather resembles the bed of a lake or, what is more probable, glacial detritus, and the characteristic surface boulders are spread over a distance of more than 12 miles, intersected by swamps mainly with a gravel bottom. Three beaver dams that have to be crossed before reaching Sibolla creek show evidences of considerable wear, and should rain fall this month (October) horses with packs will not be able to get through to the field; the water above the dams is low and the frost has been severe during the past week.

Andy Goodwill, one of the original locators, and partner had four packhorses and expect to spend the winter on No. 1 below Discovery, where the first coarse gold was recovered. C. P. Price, also one of the original locators, who is outfitting at Telkwa for a similar purpose, states that when coming out by a new route from the Sibolla country he discovered on the same range, about 12 miles to the north, a similar creek to the Sibolla, in which colors were plentiful. More than 300 claims have been staked, but with the exceptions above noted, no party of prospectors had been outfitted properly to reach bedrock in what is, to all surface appearances, a most promising field. If the men now on the ground fail for the present, in all probability the value of the field will not be determined until next year. The time actually occupied in going in from Telkwa was 6½ days, and in coming out, traveling light, 5 days.

In 1906, Herbert Carmichael, then provincial assayer for British Columbia and assistant to the provincial mineralogist, visited Kemano river; a short account of that visit was printed in the 'Annual Report of the Minister of Mines for British Columbia, 1906,' pp. H. 67-8. From that account the following notes have been taken:

"Kemano river flows into Gardner canal on the northeast side, 30 miles from the mouth of the canal. It is a stream of considerable size and is navigable for canoes a distance of 20 miles, but is so swift flowing as to require 'poing' or 'lining' all the way. At the mouth of the river there is a good harbor, with anchorage in not too deep water. The mountains, which rise abruptly to a height of 4000 or 5000 feet, seem to be entirely granitic and show very marked glaciation to a height of 2000 ft. or more. At 8 miles from the mouth of the river, Pintledanne creek flows in from the north. From this creek there is a good trail, with an easy grade, to Tahtsa lake, which in turn flows into Ootsa lake. The height of the pass is said to be 4000 ft. and the distance from Gardner canal to Tahtsa lake, 20 miles. This pass seems to afford an easy route to the Ootsa Lake country." Mr. Carmichael also gave brief particulars of a copper-bearing vein, he examined, on Pintledanne creek.

According to the last annual report of the Minister of Mines for British Columbia, in 1912 there were 445 free miners' certificates, and 303 mining claims recorded in the Skeena and Bella Coola mining divisions.

FORT WORTH, TEXAS

A RÉSUMÉ OF THE TEXAS COAL-MINING INDUSTRY, AND THE FUTURE OUTLOOK AS SEEN BY THE PRODUCERS.

According to reports received by the Texas Commercial Secretaries and Business Men's Association from many of the important coal producers in this state, the demand for Texas coal this winter will be the heaviest in the history of the industry. Labor troubles in the Colorado fields, the results of which will probably extend far into the winter, have caused a curtailment in the output of that state during the past sixty days. The Texas mines will be, and are, materially benefited by these conditions, as a large portion of the consumers which formerly secured their coal from Colorado fields are looking to Texas for their winter fuel. Many future orders have been booked by the Texas mines for shipment to dealers in southern Colorado, Texas Panhandle, and other points in the Colorado trade territory. No authoritative estimate of the total production of the Texas mines has yet been made, but it

is expected that the output of 1913 will greatly exceed that of 1912, which was the maximum annual yield, both in tonnage and value, and was the first time in the history of Texas coal mining that the production exceeded 2,000,000 tons. The annual consumption of coal in this state, according to the best available estimates, is valued at \$7,500,000. According to figures just compiled by the U. S. Geological Survey, the 1912 output of Texas was 2,188,612 short tons, valued, at the mines, at \$3,655,744. Compared with 1911, this is an increase of 214,019 short tons, or 10.8% in quantity, and \$382,456, or 11.7%, in value. The bituminous mines which are situated in Eastland, Erath, Maverick, Palo Pinto, Webb, Wise, and Young counties, in 1912 produced 1,197,907 short tons, or 54% of the total production, and it had a mine value of \$2,774,956. There were 990,705 short tons of lignite produced that year, with a value of \$880,788. The lignite mines of Texas are situated in the counties of Bastrop, Hopkins, Houston, Lee, Leon, Medina, Milam, Rains, Robertson, Titus, Van Zandt, and Wood. The leading bituminous producing counties are Eastland and Erath, and in 1912 produced more than two-thirds of the bituminous output. Lignite is produced chiefly in Wood county.

In view of the optimistic prospects for an increased business, many improved methods of mining have been instituted in Texas mines recently, and in several instances machine mining has replaced old fashioned hand-pick methods. Of the total production of last year, 105,400 short tons was mined by machine, compared with 71,085 short tons mined in this manner in 1911. Five per cent of the total production is mined by hand, and it consists principally of bituminous. Another modern improvement in the Texas mines is the establishment of washing plants in the Eagle Pass district. In 1912 there were 25,600 short tons of coal put through this process, thereby greatly increasing its market value.

The scarcity of labor has, to a certain extent, affected the Texas output during the past sixty days, but as the crop-gathering season nears an end, and labor becomes available, practically all the mines are operating full time and in some instances double shifts are being worked. The coal and lignite mines of this state furnish employment to an average of about 5000 persons the year around. The total number employed in 1912 was 5127 men, who worked on an average of 230 days during the year. The average production per man for the year was 424 short tons, or 1.84 short tons per working day. Infrequency of labor troubles has contributed toward the rapid advancement of this industry, and fewer strikes are recorded for Texas than any other coal-producing state. Only four instances of idleness from this cause were reported last year, the longest period being ten days. Only 238 men were affected, and the average number of days lost by each man was seven. As a usual thing, the bituminous mines are worked 8 hours per day and the lignite miners average 10 hours.

The Texas mines are well equipped with safety devices and every precaution to safeguard employees' lives is used. Owing to the careful and systematic manner in which operations were carried on, only two fatalities are reported for last year. In one instance a miner lost his life in a shaft, while another was killed on the surface. There were no fatal accidents in the Texas mines during the previous year. Data compiled by the U. S. Bureau of Mines and published in a recent bulletin shows that Texas has one of the lowest mine death-rates of any coal-producing district in the world.

The history of coal-mining in Texas dates back to 1884, when 125,000 short tons was produced. The yield gradually declined each year until 1888, when the production again became normal. For the next thirteen years the annual output steadily increased, until the discovery of petroleum in the Beaumont fields in 1901. Following this discovery, the coal-mining industry of Texas received a temporary setback, but with the decline in production and the subsequent increase in the price of fuel oil, a few years later, interest in coal-mining was resumed and the industry from that day has thrived.

General Mining News

ALASKA

CORDOVA

The Dan Creek Mining Co., of New York, owns 700 acres of placer ground on Dan creek. A hydraulic plant was practically destroyed by floods in September 1912, but has been rebuilt. The main reservoir is three miles from the mouth of the creek, and over 100,000 ft. of 15 to 30-in. pipe and 650 ft. of flume carries the water to the penstock. Two 6-in. giants will be used, and a 5-in. giant for stacking tailing. The sluice-boxes are 1800 ft. long and 5 ft. wide. The Company also has a sawmill and repair shop, store, and bunkhouse. G. H. Birch is the engineer in charge. The Nelchina placer district has been briefly examined by G. C. Martin of the U. S. Geological Survey, who states that at present it is not possible to make any definite statements.

EFFECTS OF THE STORM AT NOME.

Some of the claims are worthy of development on a larger scale, but the stampede was not justified. The prevailing rocks are sandstones and shales underlain by volcanic beds and cut by numerous small dikes. The valley is 110 miles from Knik.

FAIRBANKS

The Newsboy mine produced gold valued at \$8549 from 391 tons of ore crushed in the stamp-mill during September. Three feet of rich ore has recently been cut at 200 feet. L. M. Drury is superintendent.

JUNEAU

The Alaska Treadwell Gold Mining Co. will add to its equipment for electric drive four motors of 10, 35, 75 and 100 hp. respectively, switches, etc. Also there will be installed in the power-plant of the Alaska-Juneau mine a 937 kva. Curtis turbo-generator with 7-kw. motor-generator exciter set, three 333-kva. water-cooled transformers and a switchboard. The company has contracted with the General Electric Co. to furnish the equipment.

NOME

With the energy and money at their command, the resi-

dents of this recently damaged town are rebuilding, but more help is needed from the 'outside'.

The dredge at the mouth of Peluk creek was carried by a large wave 800 ft. from the beach up the creek, but suffered no damage. The American Dredge Building & Construction Co. of Seattle were the builders of this machine. The accompanying half-tone should give an idea of the effect of the storm at Nome. It started on October 1 and attained its maximum strength on the 5th, when the waves wrecked every building on the south side of Front street. With a few exceptions, merchants saved the most of their goods, but people at the east and west ends of the town lost everything. The town of Solomon, 30 miles east of Nome, was completely destroyed. The whole summer was marked by a shortage of water for placer mining.

ARIZONA

GILA COUNTY

(Special Correspondence.)—At the Miami copper mine actual development has been started for extraction of the Captain orebody. The sinking of the Captain shaft has been completed to the 420-ft. (main tramming) level, and a sump cut. On the 420-ft. level, 1894 ft. has been completed to date, and a number of raises have been started from this level to develop the ground. The first sub-level to be opened will be at 270 ft. and the work on this will begin at the Captain shaft. Diamond-drilling has been discontinued for the present. The daily output is averaging 3000 tons of ore, and the additions to the crushing plant are practically completed and will be operating within a week.

At the Southwestern Miami, drilling is proceeding at a satisfactory rate, and since the erection of coal bins at the terminus of the Live Oak branch of the railroad at a point a quarter mile north of the Company's plant, more steady and economical operation is assured. Hole No. 15 is now 1155 ft. deep; No. 16 is down 787 ft., and No. 17 449 ft. No. 15 and 16 are in silicified schist.

Miami, October 24.

(Special Correspondence.)—The Silver King mine, in the Superior district, will probably soon be reopened. At the Reymert mine, new boilers from El Paso are being installed for the new pumps.

Globe, October 23.

The General Engineering Co. of Salt Lake City, Utah, J. M. Callow manager, has received instructions from the Magma Copper Co., of Superior, to proceed at once with the design and construction of a 150-ton concentrating plant, to be built at the Company's

mines, at Superior. This property is controlled by the Gunn-Thompson interests, and construction work is expected to start within thirty days.

The Inspiration Consolidated Copper Co., Miami, will place in operation in its power-station four large 2000-kva. water-cooled transformers, a 500-kw. 4-unit flywheel motor-generator set with controlling equipment, two 580-hp. motors, switchboard and accessories.

MARICOPA COUNTY

Quicksilver weighing 1500 lb. is being produced daily by the Sunflower Cinnabar Mining Co., 75 miles northeast of Phoenix, in the Mazatzal mountains. High-grade ore is being mined from four adits, and the product will be sent to the New York branch of a San Francisco firm.

MOHAVE COUNTY

At a depth of 200 ft. on the Lexington vein, a cross-cut has passed through 24 ft. of ore, 8 ft. of which is rich in gold. The ore is said to be similar to that from the Tom Reed mine, 1½ miles distant. The flow of water is 70,000 gal. per day at present. There are eight claims in the group, and H. E. Woods is general manager. The Bi-Metal

mine is being sampled by A. B. Richardson of the Mines Company of America.

PIMA COUNTY

(Special Correspondence.)—I. N. Kinzie, of Douglas, has purchased the Silver Hill group of claims in the district of that name, from R. R. Richardson and A. E. Crepin of Patagonia. Mr. Richardson formerly owned the Three R. mine sold to N. L. Amster.

Globe, October 23.

YAVAPAI COUNTY

On the Emporia claims, two shafts have been sunk 100 ft. apart, 205 and 175 ft. deep, respectively. Stopping above the 70-ft. level has opened a considerable tonnage of ore, while the 100-ft. level is promising. In addition to the sulphide ore opened on No. 1 level, there is also from 5 to 17 ft. of \$8 oxidized ore. At the Home Run, 2 ft. of \$60 ore has been developed by T. J. Lalrd.

A 10-stamp mill is to be erected at the Fortune mine on Big Bug creek, as the 900 ft. of underground work done has opened considerable ore. About 20,000 tons of old tailing at the Crown King, in the Bradshaw mountains, has been bought by N. H. Getchell, who will treat it by the 'Monell' process. The Lynx creek dredge is to be moved to a new site.

YUMA COUNTY

At a depth of 20 ft. in the Bouse McMahon claims, six miles west of Bouse, 18 in. of high-grade gold ore and 4 ft. of copper, gold, and silver ore has been opened. On the surface the vein trended for 175 feet.

CALIFORNIA

AMADOR COUNTY

At the Plymouth Consolidated mine, according to a message sent to London by W. J. Loring, three days' work, 25 ft., on the 2000-ft. level, averaged \$12 per ton, for the full size of the drift, for part of the width of the vein. Dividends have been paid by the following companies: South Eureka, 7c. per share, equal to \$21,000, making this year's total \$209,991; Bunker Hill, 2½c. per share; and Fremont Consolidated, 2c. per share, equal to \$4000, making \$36,000 for the current year. In the Kennedy Extension v. Argonaut suit, the latter has completed its direct testimony. The Rhetta mine and about 500 acres of ground surrounding it, at Plymouth, has been bonded by Mr. Williams, manager of the Mammoth copper mine in Shasta county, which is owned by the United States Smelting, Refining & Mining Co. Mining men in the district are much interested in the deal. The New London mine, which is adjacent to the Plymouth Consolidated, has been bought by Bewick, Moreing & Company.

BUTTE COUNTY

Three dredges at Oroville yielded gold worth \$6090 during the week ended September 13.

NEVADA COUNTY

(Special Correspondence.)—On the 600 and 800-ft. levels, the old Oustomah oreshoot which was lost on the 500-ft. level has been found again about 6 ft. back in the foot-wall. Stopping is being done on both levels with machine drills, and the 10-stamp mill is working full time. The main shaft is 1000 ft. deep and sinking to 1500 ft. has been commenced. The mine is in a satisfactory condition and is being profitably worked. E. C. Klinker is superintendent of the property, which is operated by the Grizzly Ridge Mining Company.

Nevada City, October 20.

SISKIYOU COUNTY

The Belgium Bohemian Mining Co. has cabled from Holland ordering the suspension of activities at the Hyland mine. It is stated that the added expense for operating the mine during the winter is heavy, and that the Company will reopen next spring. About 25 miners are affected by this action.

A number of employees of the Black Bear mine, near Sawyers Bar, narrowly escaped drowning when water broke through an old excavation on October 26 into the 400-ft. level. The water rose 60 ft. in the mine and did considerable damage.

TRINITY COUNTY

Ten men are driving the 1140-ft. tunnel, of which 350 ft. has been completed, for the Olmstead mine, near Hawkins bar on the Trinity river. Other men are building a flume from the headwaters of Cedar creek to the tunnel and to the mine. The ditch, flume, and tunnel will be 4½ miles long when finished next February.

(Special Correspondence.)—At the Enterprise property in the East Fork district, which has been operated for the past two years by R. A. Skinner and J. D. Day, under lease, which expired September 1, the mill is being overhauled and the water system improved prior to resumption of work in the mine, under a new lease for five years, which has been granted by the owners, an Eastern company. This is the result of the splendid showing made by Messrs. Skinner and Day through their careful management during the past two years. The mine is equipped with a 10-stamp mill, concentrating table, compressor, electric light plant, and pump. Water power is used.

The ore is largely free milling, mixed at times with high-grade galena.

Helena, October 24.

YUBA COUNTY

A meeting of the Tarr Mining Co., which has a property on the Yuba river, near Smartsville, was held on October 15, to make application to the Superior Court for a dissolution of the Company; but there were not sufficient shareholders present to carry the motion. The Company took a lease on the old Blue Point mine, at one time a fair gold producer, but on examination by an engineer condemned it as unprofitable. The mine has practically new equipment, and there are no debts to be paid.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The dismantling of the Pelican mill, so far as tearing out the old machinery, was completed on October 18, and on the following Monday J. B. Ballantine started work in installing the new Edison rolls and other equipment. It is stated that electrolysis will play a part in the separation of the various metals contained in ores to be treated here. This plant will be ready for work within 60 days.

Fifteen men are employed at the Pennsylvania mine, on the west side of Argentine pass. Some rich smelting ore has been opened, and there is a good tonnage of other ore for the mill. At the Capital mine, the 550-ft. station has been made, and a hoist installed on the 540-ft. level. The main raise is being driven by three shifts. The various lessees at this property, the Waldorf, Manhattan Union, Virginia City, and on Democrat mountain are keeping busy. Georgetown, October 21.

GILPIN COUNTY

At a meeting held at Black Hawk recently, about 100 miners desired to secure tributes in the Phoenix-Burroughs mine, on Quartz hill. Ore worth \$7 to \$14 per ton in zinc, copper, and iron has been opened on the 100-ft. level of the Gunnell-Fagan lode. A new concentrating plant has been built at the London mine, at Twelve Mile. Lessees at the West Baker, Maryland Extension, Luzerne, and Keystone claims appear to be getting satisfactory results. The Frontenac Mines Co. closed its property a fortnight ago, but will resume early in November.

LAS ANIMAS COUNTY

One striker in the Forbes' camp was killed, two fatally wounded, one mine guard killed, and one wounded in the battle which took place at the Forbes tent colony between the strikers and deputies on October 17. This is the first serious engagement since the opening of the strike, and Sheriff Grisham has declared that the situation is beyond control. No one is allowed within the strikers' lines, and it is impossible to tell the number who were hit, but it is believed that more were wounded than the leaders will admit. No portion of the camp escaped the rain of lead from the machine gun. There are 11,232 men on strike who are losing \$33,000 per day in wages, while the loss to the people in southern Colorado is about \$115,000 per day.

Further trouble started on October 28 between 1200 strikers and 300 mine guards. Martial law has been proclaimed and the Colorado National Guard has gone to the scene of trouble. During the 35 days of trouble, the following summarizes the results: battles and skirmishes, 18; killed, 28; wounded and injured, 41; personal assaults, 6; buildings and bridges wrecked or damaged by dynamite, 11; property loss (estimated), \$50,000; and loss in wages (estimated), \$2,500,000.

THE SAN JUAN

The Brown Mountain smelter at Ouray is now treating nearly 100 tons of ore per day, of which 40 tons comes from the Wanakah mine. At the Sunnyside mines at Eureka, an electrostatic plant has been continuously in operation since February 1912. The tonnage treated here is about 20 tons per day, and 90% of the total feed passes a 150-mesh screen. Only a scrap or oversize screen is used, no sizing being necessary. The average assays of the products for a typical month are, heads: gold, 0.20 oz.; silver, 15 oz.; lead, 11.8%; zinc, 30%; and iron, 10.2%; pyrite: gold, 0.33 oz.; silver, 19 oz.; lead, 15.6%; copper, 3.6%; zinc, 12.6%, and iron, 26.1%; and zinc: gold, 0.14 oz.; silver, 5.3 oz.; lead, 3.6%; zinc, 41.3%, and iron, 3.7 per cent.

TELLER COUNTY (CRIPPLE CREEK)

A three years' lease on the Beacon hill properties of the Requa-Savage Gold Mining Co. has been let to K. Macdermid of Colorado Springs. This Company controls 4239 acres of ground, which will be prospected for the time being through the Common-Wealth company's shaft. Machine drills will be used by the lessee and a sub-lessee. The Requa-Savage has yielded \$160,000 so far, paying \$8070 in dividends.

IDAHO

SHOSHONE COUNTY

The town of Mullan is in an exceedingly prosperous condition, there being about 1000 men employed in the vicinity who receive over \$100,000 monthly in wages. A 300-ton concentrating plant is being installed in the old Black Bear mill building a few hundred feet from the Frisco mill, for the purpose of treating ores taken from the Frisco mine, now being reopened. At a depth of 330 ft. good ore is being extracted from the Ray-Jefferson mine, the shoot being 200 ft. long. An intermediate adit will be driven 400 ft. lower. At the Goldback, east of Murray, a vein 17 ft. wide, containing 6 ft. of galena and blende and 11 ft. of quartz heavily mineralized with iron pyrite and galena, has been opened. The development is causing considerable interest in the district. The placer ground adjacent to Murray, including Prichard, Beaver, Trail, and Eagle creeks, has been examined by C. C. Moore and Wat. Moore, who have spent several years in Alaska. A detailed map of the copper district of the Coeur d'Alene has been prepared by John H. Nordquist of Wallace. During the year ended August 31, the Federal Mining & Smelting Co. obtained the following results:

Ore reserves (milling), tons	1,050,000
Ore milled, tons	637,900
Concentrate produced, tons	84,533
Metal content of concentrate:	
Lead, per cent	43.4
Silver, ounces	15.9
Gross earnings	\$3,553,325
Operating profits	559,511
Other income	567,463
General expenses, new construction	293,526
Dividends on preferred stock	719,166
Surplus	114,282
Previous surplus	1,324,026
Total surplus	1,438,308

The Stewart Mining Co. reports as follows for the third quarter of 1913:

Gross value of mine and mill products	\$335,032
Net earnings	205,116
Development and prospecting	14,681
Net income	190,435
Cash at September 30	451,852

Dividends and bonus paid October 3 were 10% and 2.5% respectively.

MICHIGAN

HOUGHTON COUNTY

During the previous week, Calumet & Hecla shipped 5040 tons of 'rock' daily, compared with over 9000 tons prior to the strike; Osceola, 2640 tons; Copper Range, 1200 tons; Quincy, 1200 tons; Centennial, 480 tons; and Allouez, 300 tons.

MONTANA

JEFFERSON COUNTY

The Cataract mining district, near Basin, is attracting attention, and a fair tonnage of ore is being sent to the smelters. The bulk of this ore comes from the Bullion, Crystal, Comet, Baltimore, and Ruby properties, also from a large number of smaller ones.

LINCOLN COUNTY

(Special Correspondence.)—The Triplex group of silver-lead ore claims, which is located near Troy, has been bonded to W. E. Schuck of Spokane for approximately \$100,000, with a good cash payment. This property is near the B. & B. group, lately purchased by Leo Greenough of Spokane, and also the Big Eight group, recently purchased by the Federal Mining company of the Coeur d'Alene. Mr. Schuck intends to start a one-mile tunnel to develop the property at depth, and will extract the ore on the north side of Grouse mountain, which will bring the workings within six miles of Troy. Work is in progress on the placer claims south of Libby owned by William Criderman and C. E. Lukens, the intention being to install a hydraulic plant, which is to be ready for operation by next summer.

Libby, October 20.

NEVADA

The Nevada Tax Commission has cited several hundred mining companies throughout the state to show cause why an increase should not be made in their assessed valuation, and has cited nearly all the public utilities in the state for a similar reason, it being considered by the commission that they have been under-assessed.

ELKO COUNTY

The Contact mining district is said to be quite promising, and it is probable that a railroad will be constructed to it before long from the Oregon Short Line. The ore-bodies contain copper with a little gold and silver, and Henry Smith, manager of the Nevada Copper Mining, Milling & Power Co., states that the ore is high grade.

ESMERALDA COUNTY

The Goldfield Consolidated company is plaintiff in a suit to prevent the removal of \$50,000 worth of tailing from the Camp Bird, Last Dollar, and Xmas No. 1 claims by the Old Sandstorm Annex Gold Mining Co. A restraining order was saved on the latter Company on October 20. The dispute will be heard at Carson City before the United States District Court.

September results of the Goldfield Consolidated company were as follows, according to the general manager, Albert Burch:

Ore treated, tons	27,979
Net realization	\$177,875
Operating costs per ton:	
Mining (stopping and development)	\$3.27
Shipping expense	0.20
Dump moving	0.12
Transportation	0.09
Milling	1.87
Marketing	0.07
General expense	0.33
Bullion tax	0.21
Flood damage*	0.14

Total costs	\$6.30
Miscellaneous earnings	0.12

Net costs

*The cloudburst occurred on September 13, and although

precautions had been taken in May, the lower levels of the Mohawk, Laguna, and Clermont mines were flooded, and considerable damage to the upper levels resulted from the flow of water through them. The total cost of the flood was \$3886, including surface and underground, and on October 15 the last of the water was removed. Development covered 2985 ft. at a cost of \$4.53 per foot, with little of importance to report.

STOREY COUNTY

Two air-compressors, formerly used at the Ward shaft, are being moved to the C. & C. shaft of the Comstock Pumping Association, to be used for the Starrett pumps in the Con. Virginia winze below the 2500-ft. level.

LYON COUNTY

During the week ended October 22, the Mason Valley smelter received 2245 tons of copper ore from the Mason Valley, 1163 tons from the Nevada-Douglas, and 818 tons from other mines in the Yerington district. The new mill at Pine Grove is working full time treating gold and silver ore.

NYE COUNTY

(Special Correspondence.)—At a depth of 790 ft. the Railroad Valley Co.'s No. 6 drill-hole had passed through 165 ft. of clay containing 30% of gaylussite, this making three holes in this deposit. No. 6 hole will be sunk deeper, and another will be driven south of it in search of potash. Gaylussite has been found in clays over five square miles of the valley. It is a new occurrence of this mineral, and is of some commercial importance as a source of soda in the event of a railway or other means of transport being available.

Railroad Valley, October 27.

During the week ended October 25, the mines at Tonopah produced 10,954 tons of ore worth \$264,910. The North Star shipped 100 tons, half of which averaged \$24 per ton. This came from a stope above the 1050-ft. level. Four to five feet of rich ore has been opened in a raise above No. 12 level on the Mizpah Fault vein in the Belmont. The mine generally is developing most satisfactorily. At the Extension, developing the Murray vein from the new shaft, 950 ft. deep, is opening large reserves of ore. On the 760-ft. level, the cross-cut passed 16 ft. of ore, 4 ft. being of good grade, while the east and west drift opened 277 ft. of the vein. On the 850-ft. level the vein is of similar size. Cross-cutting is in progress at 950 ft. During the quarter ended August 31, the Tonopah Mining Co. treated ore worth \$717,275, yielding \$641,814, with net earnings of \$308,899. Dividends paid were \$400,000; loans made, \$100,500; exploration and investment, \$23,837. Cash on hand at August 31 was \$249,776.

NEW MEXICO

COLFAX COUNTY

About 260 miners were entombed in No. 2 shaft of the Stag Cañon coal mines at Dawson when an explosion occurred at the property at 3 o'clock on October 22. Five of this number, found on an upper level, were taken from the mine that night, and rescuers have arrived from all parts of the southern Colorado fields. The day shift working in No. 2 shaft numbered 280 men. The cause of the explosion is unknown. Mine-rescue cars from Denver and Trinidad, Colorado, are at the mine, and miners are driving through the cave-in caused by the explosion. Later reports state that all hope for further rescue is at an end, and fully 260 men have lost their lives.

The property is owned by Phelps, Dodge & Co., of New York, and during 1912 the coal output was 1,383,562 tons from five mines. Of this, 646,061 tons was converted into 319,221 tons of coke for the Copper Queen smelter at Douglas, Arizona. Only six lives were lost in 1912. A rescue station containing eight helmets and plenty of oxygen and potash is always ready for emergencies. The Stag Cañon Fuel Co. paid \$414,927 in dividends in 1912.

The U. S. Bureau of Mines has just issued Bulletin 50, 'A Laboratory Study of the Inflammability of Coal Dust,' by J. C. W. Frazer, E. J. Hoffman, and L. A. Scholl, Jr., which should be studied by those interested in coal mines.

WASHINGTON

FERRY COUNTY

The San Poil Consolidated Co.'s cyaniding mill is now treating a daily output of 110 tons of ore from the San Poil and Knob Hill mines, and occasionally more than the rated capacity of 125 tons per day. A new Williams hammer-mill, with a thicker and stouter shell and larger and heavier hammers, replaced the first one and has been breaking all the ore to $\frac{3}{4}$ -in. mesh. The capacity of the new hammer-mill is over 10 tons per hour. A Taylor 6 by 8-ft. tube-mill has been installed to work with the 5 by 22-ft. Gates tube-mill.

KING COUNTY

The Seattle Assay Office has temporarily stopped receiving gold on account of an order from Washington, D. C. It appears that an appropriation for transport of uncoined gold has not been made. A similar situation arose seven years ago, and nearly \$3,500,000 in gold was stored at Seattle awaiting funds for its removal to the mints.

CANADA

BRITISH COLUMBIA

Le Roi No. 2 company reports the shipment of 1644 tons of ore and 85 tons of concentrate in September. The smelter receipts were \$33,404. Total costs were \$16,100. The Josie drift was advanced 56 ft., 40 ft. averaging \$12 gold and 5% copper over 13 in.; the Annie drift, 700-ft. level, was driven 92 ft., 10 ft. assaying \$1.45 gold and 5.5% copper over 3 in.; in the Josie cross-cut and drift, 22 ft. averaged \$7 gold and 1.25% copper over 18 in.; and the Hamilton vein west, 600-ft. level, averaged \$9 gold and 0.87% copper across 25 in. The Van Roi mill crushed 587 tons of ore from development assaying 4.7 oz. silver, 1.9% lead, and 5.3% zinc during a 96-hour run, yielding concentrate worth \$864.

ONTARIO

On November 15 the Crown Reserve company, at Cobalt, will pay a dividend amounting to \$35,276, making a total of \$5,437,538 to date. The McKinley-Darragh-Savage mines yielded 242,266 oz. silver in September, of which nearly 100,000 oz. came from the shoot in No. 40 vein on the 150-ft. level. A total of 5461 tons of ore was treated at the mill. A steam hoist of 1500 to 2000 ft. capacity has been ordered for the Beaver Consolidated shaft, which is down 800 ft. On the 460-ft. level a 4-in. vein of quartz and calcite was cut last week, the calcite assaying up to 6000 oz. of silver per ton. A new calcite vein, $1\frac{1}{2}$ in. wide, has been cut on the 700-ft. level. Shortage of water has affected the power situation at Cobalt, and the 18 mills in operation have been stopping one after another for 24 hours. The Ontario Light & Power Co.'s hydro-electric plants are running 25% overload. A recent fall of snow should help considerably, as the snow melts at this time of the year. The steamship companies have reduced the rate for carrying silver to London from their recently fixed charge of \$7 to \$6 per 100 pounds. The Nipissing sent 85,055 oz. to New York, and the Buffalo 60,802 oz. to London last week.

MEXICO

SONORA

The El Tigre Mining Co., operating at Yzabel, reports for September that the stamp-mill crushed 5633 tons of ore, and the cyanide plant treated 5330 tons of current and 1835 tons of dump tailing. The revenue from this plant, shipping ore and concentrate, was \$133,989, and estimated profit \$58,562. On October 2 a dividend of 5c. per share was declared. At a meeting of the directors in Kansas City, Missouri, on October 16, it was decided to increase the monthly dividend to 6c. per share, as there is only \$72,600 still outstanding of the total issue of \$400,000 of bonds, and the present condition of the property justifies this action. The recently discovered orebody is to be called the Kelley vein. It is 150 ft. east of and parallel to the Tigre vein, and its course is north and south with well defined walls. High-grade ore has been opened throughout, and cross-cuts have been started in three places from the Tigre vein.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. W. PURINGTON has returned to London.
S. H. BRADY was in San Francisco last week.
J. A. AGNEW has returned to New York from Peru.
J. SAXTON is returning to England from West Africa.
H. S. UNDERWOOD has gone to Broomassie, West Africa.
ROBERT HOLMES was a recent visitor to San Francisco.
MAX J. WELCH will be in Los Angeles during November.
W. W. MEIN was in San Francisco last week and this.
WHITMAN SYMMES was in San Francisco part of last week.
R. G. THOMAS has sailed from New York for Northern Nigeria.

A. D. FOOTE and WILLIAM HAGUE were in San Francisco last week.

A. J. HOWE has returned to Costa Rico after visiting San Francisco.

C. H. ROWLANDS is in London, having left Hostotipaquillo, Jalisco, Mexico.

C. H. WRAY sailed from New York on October 22 for Northern Nigeria.

LEO VON ROSENBERG was recently in the Ray and Globe districts, Arizona.

ARTHUR B. FOOTE was married October 23 to JEANETTE S. HOOPER at San Francisco.

LOUIS A. WRIGHT passed through San Francisco on his way to Nevada this week.

JOHN POWER HUTCHINS was married to Miss ELISABETH MCNEAR on October 15 in London.

L. M. DUBRY has been appointed manager for the Newsboy Mining Co. at Fairbanks, Alaska.

E. T. BORLASE has left Rio Tinto for the mines and railways department of the Huelva Copper Co., Valdemusa, Spain.

F. W. MACLENNAN is the new mine superintendent for the Miami Copper Co., at Miami, Arizona, who succeeds N. O. LAWTON, resigned.

J. G. HOPKINS, Y. J. PENTLAND, and GEORGE READMAN, directors of the Arizona Copper Co., are making an extended visit to the property at Clifton.

JAMES DOUGLAS left Globe, Arizona, on October 22 in his special car for Dawson, New Mexico, to personally look into the accident there at the Stag Cañon coal mine.

W. H. TANGYE has resigned as superintendent of the Calumet & Sonora of Cananea Mining Co., and will leave immediately for California. PAUL PROBERT has been appointed temporary superintendent. The mining operations are in charge of T. MCGOVERN.

HENRY N. THOMSON has resigned as superintendent of the Tooele plant, of the I. S. & R. Co. in Utah, and WILLIAM WRAITH assumes the combined duties of manager and superintendent. He will be assisted by O. M. KUCHS, formerly head chemist at the plant.

Among those present at the American Institute of Mining Engineers' meeting held in New York on October 16 and 17 were JOHN A. CHURCH, A. S. DWIGHT, KARL EILERS, H. O. HOFMAN, HENRY M. HOWE, ROBERT W. HUNT, GEORGE F. KUNZ, A. R. LEDOUX, R. W. RAYMOND, W. L. SAUNDERS, W. F. STAUNTON, ARTHUR L. WALKER.

Among those attending the sessions of the American Mining Congress in Philadelphia last week were D. W. BRUNTON, JOHN R. BURTON, H. M. CHANCE, W. R. CRANE, H. N. ELMER, MARTIN D. FOSTER, F. LYNWOOD GARRISON, GEORGE H. GARREY, R. W. GUNNELL, HENRY JENNINGS, E. B. KIRBY, H. N. LAWRIE, J. W. MALCOLMSON, C. M. MODDERWELL, A. J. MOORSHEAD, R. V. NORRIS, SIDNEY NORMAN, C. J. NORWOOD, E. W. PARKER, J. W. PAUL, C. W. PARSONS, P. J. QUEALY, THOMAS T. READ, GEORGE S. RICE, D. B. RUSHMORE, CARL SCHOLZ, H. L. SMYTH, L. H. TAYLOR, JR., H. N. TAYLOR, KIRBY THOMAS, C. R. VAN HISE, C. E. VAN BARNEVELD, B. W. VALLAT, J. L. WARR, WILLIAM B. WILSON.

Obituary

L. W. POWELL, a mining operator prominently connected with various enterprises at Bisbee and elsewhere in the southwest, died at Los Angeles of heart failure, October 25.

WILLIAM NELSON, editor of the *Salt Lake Tribune*, a paper which has long been noted for the excellence of its local mining news, died at the age of 74 at his home in Salt Lake City, October 26.

ROBERT M. MEIN, who died in his home in Oakland, California, October 26, was a son of the late Thomas Mein, the well known California mining engineer, who was one of the South African pioneers. Robert Mein followed his father and brothers in the profession and both in America and the Transvaal was active in the work. He served as assayer in the Far North, as agent for Fraser & Chalmers on the West Coast, and in general consulting work. He was a capable, loyal, likeable young man who, dying at the age of 38, leaves many sorrowing friends.

J. P. KIMBALL, who died at Cody, Wyoming, a few days since at the age of 77 was one of the pioneer mining geologists of America. After graduating at Lawrence Scientific School and studying at Berlin and Gottingen, he became assistant to J. D. Whitney in his geological survey work in the Mississippi Valley and in making private examinations. Later he was professor of chemistry and geology in New York Agricultural College and connected with various iron-mining enterprises along the Atlantic coast. He was one of the first to study the mineral resources of Cuba and a pioneer in mine examination work in South America. He published little and the younger generation knew little about him, but he has left a record of clean honorable work.

JOHN COIT ADAMS, assistant general superintendent for the Anaconda Mining Co., died at Butte, October 17, after a protracted illness. He was born in Honolulu in 1867 and after graduating at Harvard and the Massachusetts Institute of Technology came to Montana to become assayer at the Hope mine, at Phillipsburg. Later he went to the Bimetallic and became foreman of the mill. He left this position to engage in general expert work, and in 1896 removed to Butte as consulting engineer for H. L. Frank. In 1901 he became foreman at the Pennsylvania mine; from this he rose to superintendent of mines for the Boston Montana, and when the new Anaconda company was formed he was made assistant general superintendent. Mr. Adams was one of the best liked men in Western mining circles. Sound in his technology, seasoned by his experiences, he had a gift for handling men that made him especially useful and successful. It is said that during the bitterest days of the Amalgamated-Heinze contest at Butte, he retained the respect and liking of his opponents, despite the skill and energy with which he directed the fight.

The operation of a Frenier pump is essentially that of an air-lift, a certain amount of air being compressed at each revolution of the spiral. No increase in the capacity of the pump can be attained by an increase in the speed of the spiral, and no departure should be made from the determined ratio. There is no possibility of obtaining excess air pressure, and it is therefore imperative that the discharge should be free and unhindered. To this end the precaution observed in the lay-out of an air-lift installation should be rigidly observed, and all bends and elbows avoided in the discharge pipe. It is necessary that the air be allowed to escape as soon as the lifting is accomplished, and the best way to insure this is to provide a vertical discharge directly into the bottom of a short launder having a sharp fall. In operating a pump the pulp should be kept at a definite level in the box. Where it is impracticable to arrange for the pump to have its exact load, maximum efficiency and minimum of trouble will result by arranging an overflow exit from the box at a fixed pulp level. The excess pulp can then be handled by a separate arrangement such as a variable-feed self-operating air-lift, which will require power for operation in almost direct proportion to the excess pulp handled.

New York Metal Market Review

The feature characteristic of all the metals in October was dullness, and with the quiet trade came declining prices. Despite the absence of demand, however, copper recovered near the close of the month, because of foreign influences. Spelter declined steadily, but like copper showed a better tone late in October. Lead was reduced repeatedly and prices are regarded as too low for the good of the American consumer. Antimony has been without interest. Pig tin has been inactive, and less business is expected in the next few months. Aluminum has been adversely affected by the seeming slacking up in the automobile trade, or its slowness in getting started, and prices have declined a few points.

COPPER

Copper metal was strong at the beginning of the month, when it was quoted at 16.75c. per pound cash for electrolytic and 16.87½c. cash for Lake, but it eased off in the absence of buying, and by October 10 had dropped to 16.37½c. cash, with reports of even lower prices, which held for several days. At no time in the month was there any buying of importance and quotations of both first and second hands were almost entirely nominal. The large agencies consistently held to 16.75c. cash, for electrolytic, or 16.87½c. 30 days delivered, while for Lake they asked 17 to 17.25c. In the early part of the month there was a feeling on the part of consumers that prices had been forced up too rapidly; in other words, confidence was lacking. Even the report of the Copper Producers' Association for September, which showed a decrease in stocks of 8,520,943 lb. from those of the previous month; also that stocks on hand, 29,793,094 lb., were the lowest since the producers' records were begun five years ago, did not excite any great interest, so apathetic were consumers. The situation was attributed to the tendency, common in other metals and lines, to await the working out of the new tariff. One thing apparent was that consumers were well covered until December. To some extent, of course, the strong statistical position of the metal was offset by the falling off of domestic consumption in September, deliveries decreasing by over 7,000,000 lb. About the middle of the month, prices took an upward trend, despite the fact that important business was still lacking. The rise was due to advances in Standard copper in London and indirectly to a strike at the Rio Tinto mines in Spain. These influences caused the metal to again touch 16.75c. cash for electrolytic, and 17c. and over for Lake on October 21. On October 23 a slight weakness developed because of freer selling of standard copper abroad, but it was not enough to really affect metal prices, which, however, remained nominal. Exports to and including October 24 were 24,073 tons. The Waterbury average for September was 16.87½c. per pound.

SPELTER

Throughout most of the month spelter was in light demand, and the course of prices was downward until near the end, when the tone became better and a few points were gained. In the first few days of October, prices were around 5.75c. per pound New York and 5.60c. St. Louis, but successive reductions brought them down to 5.30c. New York and 5.15c. St. Louis. These low prices were reflected in lower prices for carload lots of sheet zinc at the mill, the quotation for which on October 24 was \$7.50 per 100 lb. basis, less 8% discount, f.o.b., cars Peru, Illinois. On October 24 the New York price for spelter was 5.45c. per pound.

LEAD

The prices of lead in October also pursued a downward trend. It was quoted at the end of September at 4.65c. per pound New York and 4.50c. St. Louis, and on October 24 at 4.35c. New York and 4.20c. St. Louis, quotations which were susceptible to a little shading. At no time was business brisk. The American Smelting & Refining Co. on October 1 reduced its price 15 points to 4.60c. New York and 4.45c. St. Louis, a move which was expected in view of the extent to which outsiders had cut prices. They

continued to undersell, and on October 8 the big interest announced another reduction, this time to 4.50c. New York and 4.35c. St. Louis. This cut was met also, and considerable eagerness to get business was shown. The hope that the market would steady at these figures was not gratified, and the outsiders again dropped a few points. On October 16 the large producers again made a reduction, coming down to 4.35c. New York and 4.20c. St. Louis. Outside producers followed, as at the new basis they could still compete with the large interest in New York and undersell in other parts of the country. The third decline did not steady the market, although at the lower prices small lot buyers came in somewhat stronger. The price last named held October 24. An interesting phase of the lead situation came up in connection with talk of a possible decline to 4.25c. or thereabout in New York. Students of the market declared that any such figure would mean danger of London coming into this market and buying heavily of domestic lead, thereby unsettling the market, causing a shortage and resultant higher prices, all to the detriment of American consumers. The price in London on October 22 was £20 7s. 6d. per ton, which is 4.45c. per pound. The discount of 2.5% which London allows in sales of lead, brings the price down 10 points, or to 4.35c. With 15 points allowed for freight, London could, under these conditions, come into this market and pay 4.20c.; therefore, it was pointed out that 4.20c. New York, and even 4.25c. New York, would be dangerous. London at the present time is not well supplied with the metal.

ANTIMONY

Activity in antimony was precluded by the large stocks in bonded warehouses which were open to entry at a reduced rate of duty when the new tariff law became operative. Prices dropped about ½c. per pound, making quotations toward the end of the month around 7.12½ to 7.25c. for Hallet's, 7.50 to 7.62½ for Cookson's, and 6.37½ to 6.75c. for Chinese and Hungarian grades.

PIG TIN

From the first of October until near the end, when this report was written, the market was quiet, with prices ranging between 40.12½ and 41.00c. per pound. The Banca sale on September 25 realized 116¼ florins, equal to 42.30c. delivered New York, but the price had little effect on the New York market, as it was felt that the high figure was obtained largely through manipulation of London prices. Deliveries in September were light, amounting to but 3100 tons. The total deliveries for nine months this year showed a decline of 3000 tons compared with the same period of last year. The total visible supply on September 30 was 12,943 tons, which was 302 tons below that of September 30, 1912. Total arrivals in September were 4234 tons. Arrivals in October up to and including October 24 were 2650 tons, and there was afloat on that day 2535 tons. The trade expects consumption by the tinplate trade to diminish in the next few months. Toward the end of October there was a slightly improved demand, but the anxiety of speculative holders to get out of the market kept prices down. It was predicted that on November 1 stocks on hand would be large.

ALUMINUM

Trade in this metal has not been active and the situation generally is unsatisfactory, all of which is attributed to the slower demand and perhaps delayed demand from the automobile manufacturers. Prices declined a few points and there were no recoveries. October 10 the metal was quoted at 20 to 21c. for prompt domestic and 20.12½ to 20.37½c. for foreign. By October 24 quotations were 19.75 to 20.25c. for prompt domestic and 20 to 20.25c. for foreign. All of these prices were for large lots, ton shipments, and 100-lb. lots ranging higher. The imports of aluminum in August were 1,336,835 lb. as compared with 576,252 lb. in the same month a year ago.

Up to the middle of October, withdrawals of gold by Egypt from the Bank of England totaled \$36,000,000. Between January 1 and the opening of autumn the Bank imported from Egypt only \$9,000,000 in gold.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, October 30.

Antimony..... 12-12½c	Quicksilver (flask)\$10
Electrolytic Copper..... 17½-17¾c	Tin..... 44-45½c
Pig Lead..... 4.60-5.55c	Spelter..... 7-7½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50	

EASTERN METAL MARKETS.

(By wire from New York.)

NEW YORK, October 30.—The copper market is quiet, the buyers holding off and but little selling is reported. Report from Rio Tinto states that the management of this famous Spanish property is determined to fight the strike to a finish, and the present outlook for a speedy settlement is not very promising. The curtailment of production due to the strike at Rio Tinto and in the Lake Superior district it is estimated will amount to from fifteen to twenty million pounds per month. The lead and spelter market is firmer, and a slightly better condition is reported. A good demand for spot tin continues, the consumers doing but little buying in futures, owing to the wide fluctuations which have taken place in the tin market during the past year. A firmer market and higher prices are anticipated owing to the increased demand for tin plate.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

June17.23	14.71	Dec.17.37

The copper market strengthened a good deal during the week ended October 25. On October 21 there was a fair amount of buying for European account at 16½c. per pound, the price to which the seller had been adhering without recording any sales. On the 22nd domestic consumers came into the market and though sales were not large the full price was paid and sales on foreign account also continued in small amount. The sale of a carload of Copper Range metal at 16½c. was reported, but Calumet & Hecla is held at 17½c. The rest of the week was featureless except that by the 24th the market had been so cleaned of spot copper that it was at a premium, 17c. being the reported price. The market was dull but strong at the close of the week. Copper exports from New York for the week ended October 23 were 8852 tons, or 24,073 tons since the first of the month. Exports for the same period last year were 20,242 tons, so the European demand has evidently not slackened yet. The London market on October 24 closed at £74 10s. for spot and

£73 12s. for futures, being up 10s. on spot and 5s. on futures. There is no sign of a 'runaway market.'

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Zinc and lead ore prices at Joplin, Missouri, at the beginning of November were much lower than for the corresponding period of 1912. Zinc sulphide is bringing \$38 to \$42, basis of 60% metallic zinc, with choice grades selling for as high as \$45 per ton. Lead ore sells for only \$52. Calamine realizes \$21 to \$22, basis of 40% metallic zinc, with choice ores selling for as high as \$26. For the corresponding week of 1912 zinc sulphide brought \$54 to \$58, basis of 60% metallic zinc, with choice grades selling for as high as \$61. Lead ore brought \$65.50. Calamine brought \$26 to \$29, with choice grades bringing as high as \$34. Spelter at East St. Louis dropped to \$5.15 to \$5.25 per 100 lb. at the beginning of November compared with \$7.40 for the corresponding time of 1912. Pig lead dropped to \$4.20 compared with \$4.80 a year ago.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

1912.	1913.	1912.	1913.

Company Reports

DE BEERS CONSOLIDATED MINES, LTD.

This Company operates the well known De Beers, Kimberley, Wesseltion, Bultfontein and Dutoitspan diamond mines at Kimberley, South Africa, and the report covers the year ended June 30, 1913. The capital of the Company is £4,500,000, in 800,000 preference and 1,000,000 deferred shares of £2 10s. each. The year's results may be best shown as follows:

Yield per load (1600 lb.) was worth \$4.68, \$3.32, \$4.76, and \$4.96 from the respective mines.

Sales of diamonds	£6,297,782
Other income	143,068
Balance brought forward	807,388
Mining expenditure	2,080,622
Depreciation	706,035
African taxation	426,465
Debiture interest and sinking fund	235,932
Profit	3,799,183
Deferred dividends paid	1,500,000
Bonus	250,000
Preference dividends	800,000
Added to reserve	140,060
Balance brought forward	513,521
Diamonds unsold	595,601
Stocks of 'blue ground' on floors, loads	10,803,054
Value of this ore reserve	£1,540,419
Investments at June 30, 1913	1,932,184

The directors of the Company report that the year's results were most satisfactory, which may be judged from the large figures in pounds sterling.

AMALGAMATED ZINC (DE BAVAY'S), LTD.

This Company operates a large flotation plant at Broken Hill, New South Wales, and buys tailing from the mining companies there. Work during the year ended June 31 may be shown as follows:

Tailing treated, tons	523,698
Zinc concentrate, tons	142,668
Lead concentrate, tons	1,841
Dividends paid during first half of 1913.....	\$480,000
Carried forward	321,000
Reserves	792,000

GIANT MINES OF RHODESIA, LTD.

This Company operates in the Gadzema district of Mashonaland, Rhodesia, and the report covers the year ended June 30, 1913. Results are as follows:

Ore treated, tons	131,887
Bullion recovered	\$864,000
Net profit	360,000
Dividends paid (partly out of balance from previous year)	370,000
Ore reserves, averaging \$8.20 per ton, tons.....	243,687

Current Prices for Ores and Minerals

Production Statistics

IRON AND STEEL

A report on the production of iron ore, pig iron, and steel, by Ernest F. Burchard, of the U. S. Geological Survey, includes statistics of production showing a highly prosperous condition in the iron and steel industries for the year, the total output of iron ore being valued at \$107,050,153, an increase of \$20,000,000 over 1911.

NATURAL GAS

The year was one of greatest prosperity to the natural-gas producer and a record breaker for output, according to B. Hill of the U. S. Geological Survey. The total estimated consumption of natural gas in the United States in 1912 was 562,203,452,000 cu. ft., valued at \$34,563,957, an average price of 15.04c. per 1000 cu. ft., compared with 512,993,021,000 cu. ft., valued at \$74,621,534, an average price of 14.55c., in 1911. The number of domestic consumers supplied with gas in the United States in 1912 was 1,621,557, and the value of gas consumed for domestic purposes amounted to \$50,960,883, while the number of industrial consumers was 15,936 and the value of gas consumed for industrial purposes was \$33,603,074. On the assumption that 28,000 cu. ft. of gas equals in heating power one ton of coal, the fuel displaced by gas consumed in 1912 was equivalent to approximately 20,000,000 tons of coal. West Virginia was the greatest producer of natural gas in 1912, the figures being 215,785,027,000 cu. ft., valued at \$29,064,968.

COPPER ORES IN 1912

The following table, from a U. S. Geological Survey bulletin, shows how the ores in the various states were treated during the past year, in short tons:

State.	Ore concentrated.	Ore smelted.
Alaska		93,452
Arizona	4,435,225	2,106,929
California		408,622
Colorado		13,718
Idaho	16,141	82,707
Michigan	11,411,941	
Montana	4,341,051	753,381
Nevada	2,986,087	290,082
New Mexico	1,121,575	74,108
North Carolina and Oregon		5,069
Pennsylvania and Maryland	224,200	1,000
Tennessee and Texas		603,251
Utah	6,098,491	572,354
Virginia and Wyoming		1,315
Washington	7,685	8,030
Total	30,642,396	5,014,018

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COST of handling slag at the Grand Forks smelter, British Columbia, averaged 5½c. per ton of ore during the past fiscal year.

GLASS AND PORCELAIN NOZZLES for cone-classifier discharge have been introduced at various mills, and have been found to give a longer life than metal bushings.

THE Victoria Falls, on the Zambesi river, have a height of from 265 to 343 ft., and a width of over 1500 ft. So far no effort has been made to make use of any portion of the available power.

A CATERPILLAR TRACTOR of 25 to 65-ton capacity has been ordered to haul ore from the Tyler lease above Wardner, Idaho, to the Bunker Hill & Sullivan mills. The engine will be driven by gasoline and will haul four trailers. The round trip will take about 2½ hours.

THIRTY-TWO MINERS were killed out of 13,813 employed at 17 different copper mines in Michigan during the year ended September 30, according to the report of Thomas H. James, inspector of mines. About 32% of the casualties were among the Austrians employed.

DEVELOPMENT WORK at the Phoenix mines of the Granby Consolidated company covered 11,517 ft. and 14,996 ft. of diamond-drilling, the totals to date being 107,848 and 76,141 ft., respectively. The average cost per ton of ore, crushed, on cars, including development, was 75.4 cents.

WHERE WATER IS SCARCE the minimum of loss from a wet-crushing treatment plant is attained by the use of hand discharging frame filter presses, in which the moisture may be reduced as low as 15 per cent. The excessive use of compressed air for the purpose of reducing moisture in the residue is, however, a doubtful economy since the last few percentages of moisture expelled from the cake are not recoverable.

BAFFLES used in connection with the settlement of slime are mainly for the purpose of breaking up surface currents. There are two zones in any dewatering device not dependent on vacuum or pressure for their operation, which may be termed the settling zone and thickening zone respectively. Baffles should not be placed below the thickening zone; and, where maximum dewatering is being aimed at, it is preferable that no baffle should extend for more than a few inches below the surface of the pulp.

THE APPEARANCE OF HYDROGEN BUBBLES is often taken as an indication of good working in a zinc-box. The hydrogen is evolved as a result of the action of the free cyanide present on the zinc; and is necessary to complete the reaction involved in connection with the separation of the gold and silver from the solution. The appearance of the hydrogen is an indication that there is more than enough to complete the reaction. On the other hand, an extractor-box having a 'dead' appearance may not necessarily be working badly, since it is possible that the necessary amount of hydrogen is being absorbed as soon as formed.

QUICKSILVER is used for many well known purposes, but an interesting and increasing use in Scotland is the floating of the lights of lighthouses upon a body of quicksilver. The metal is not consumed, of course, and the loss in use is insignificant. The commissioners of northern lighthouses, Edinburgh, have in their charge 90 lighthouses on the coast of Scotland. Up to the year 1900 the revolving lights were borne on rollers. The 'float' system has been gradually introduced, however, and is now in operation at 30 coast stations and will be used at all others. The lighting machinery rests on a pontoon which runs on quicksilver in a groove. The quantity of mercury required

for this purpose in a lighthouse is from 7 to 8 flasks of 75 lb. each. As the waste is trifling, the total present demand for this purpose is small.

AN ESTIMATION of the amount of gold in a specimen stone may be made with considerable accuracy when the actual specific gravity of both quartz and gold is known. If g_1 represents the specific gravity of the specimen, g_2 the specific gravity of the gold, and g_3 the specific gravity of the quartz, then:

$$100g_2(g_1 - g_3) = \% \text{ of gold in specimen.} \\ g_1(g_2 - g_3)$$

An approximation can be made by taking the specific gravity of the gold at 19, and that of the quartz at 2.6.

ANALYSES of the orebodies at the Granby Consolidated company's mines at Anyox, British Columbia, are as follows: The two orebodies differ in their analyses. The No. 1 orebody being higher in iron, sulphur, and lime content, while No. 2 is higher in silica, alumina, and magnesium. The table below gives the average analyses of the two orebodies:

	Orebody No. 1, %.	Orebody No. 2, %.	Orebody No. 1 and 2, %.
Silica	21.4	30.3	26.4
Iron	29.2	25.7	27.6
Lime	5.0	3.3	4.0
Sulphur	30.0	17.8	24.3
Alumina	5.6	10.6	8.3
Magnesium	1.3	4.1	2.4

THE LAST REPORT of the Central Mining & Investment Co. shows that the surface operating costs of the mines of the group have been reduced during the year, and the saving in this respect has been the most marked during the last few months of the year. The average operating costs for 1911 were 4.43s. per ton milled, and the gold recovered was 95% of the estimated content of the ore treated. The average operating costs for 1912 were 4.18s. per ton milled, and the gold recovered was 95.6% of the estimated content of the ore treated. The ratio of tube-mills to stamps has been the subject of further inquiry, and while it is not possible to establish a standard applicable to each individual mine, owing to the varying characteristics of the ore throughout the district, it is of interest to note that, as an average for the group, it is now estimated that the most economical crushing is obtained by employing a ratio of 30 to 40 of the present type of stamps per tube-mill, with mill screens of 10 to 14 I.M.M. Standard (100 to 200 holes per square inch).

ELECTROSTATIC SEPARATION of ores by the Huff method is increasing, and besides the treatment of zinc ores other fields are being entered, such as concentrating crude silver ores at Austin, Nevada; molybdenite from its gangue in Australia; to reconcentrate concentrate at Cobalt, Ontario; removing mica from graphite flake. The Canadian Bureau of Mines has installed a complete plant in its testing laboratory at Ottawa. A typical mill flow-sheet for an electrostatic plant using the Huff process consists of a cylindrical dryer, about 4 feet by 20 feet, made of sheet iron; bucket elevator to the top of the mill, carrying the dried ore to the screens. In some cases only a scrap screen is needed if the sizing required is 20 to 50 and through 50 mesh. If the various minerals will break mechanically free above 20 mesh, one or two coarse screens are necessary as 6 to 12, 12 to 20 mesh. Then the ore is taken to the separators, through which it falls by gravity, the conductors and non-conductors as separated passing directly to storage bins. Returning a small amount of middlings from each separator back into the system is beneficial in increasing the tonnage and making cleaner products. These middlings finally pass out of the system in the finished products, according to Frank S. Macgregor. The power required is small, a 3-hp. generating outfit being sufficient to electrify a plant of from one to fifty separators. The machinery of one plant is operated on 12 actual hp., which includes power for the dryer, elevator, screens, and six separators. One attendant will care for a shift, exclusive of handling ore.

STATISTICS of Canada's mineral production for 1912, recently announced, prove highly satisfactory. These figures have been collected since 1886 and since that time the per capita output has increased from \$2.23 to \$18.27.

ACCORDING to a recent press bulletin of the United States Geological Survey, the output of manganese alloys, ferromanganese, and spiegeleisen from American mines during the past year was 227,939 long tons. May we ask why the output of the brass mines has not been reported?

LOS ANGELES has been celebrating this week the completion of the great aqueduct which is to bring water from the mountains to the city. And well may the City of the Angels rejoice, for not only has a work been accomplished that will make greatly for the city's material welfare, but a great public work has been built with such honesty and efficiency as warrants renewed faith in democracy. To Mr. William Mulholland, Mr. J. B. Lippincott, and the other engineers of the staff, we offer our especial congratulations.

USE of copper to improve the quality of iron and steel is not the right line of progress, according to Mr. A. S. Cushman, who argues, in a recent bulletin of the Bureau of Industrial Research at Washington, that such procedure is simply an attempt to overcome the bad effects of the usual impurities in steel by adding an additional one. Mr. Cushman is convinced that improving the quality of iron and steel by improving its purity is the proper method of progress. Apparently the hopes of those who anticipated a new market for copper are doomed to disappointment.

OBSERVATIONS of a tourist are proverbially rated low, but, after all, their value depends upon who the tourist is and what mental attitude and how much experience he brings to his task. The informed sympathetic comment of an expert, be he ever so transient a visitor, is worth careful reading, and it is such comment that we present this week in the translation by Mr. Herbert Haas of the address delivered at Aachen last July by Mr. Ferdinand Heberlein, the accomplished Frankfort metallurgist. His comparisons of American and European practice, and his frank admission of the superiority of what he saw in the United States in certain industries, gives all the more point to his criticism in other matters where we do less well. Americans worship the big, but it is worth remembering that quality as well as quantity is important.

IMPORTANT amendments to the laws governing placer mining in the Yukon are proposed, and Mr. Alfred Thompson, member of parliament, and Mr. George P. Maekenzie, gold commissioner, have been holding conferences with miners to obtain their views.

CRITICISM is easy when directed only to finding fault, but to point a way to the correcting of evils is more difficult. In the article on resoiling after dredging, Mr. G. L. Hurst contributes a few concrete facts that warrant attention. He does not claim that the method described can be applied in every instance, but he does show that it is workable in some. If it were applied as far as possible, that would help mightily to still the criticism of the farmers and conservationists.

NOME is far from downcast at the destruction caused by the recent storm, if one may judge from the appearance of the *Nome Weekly Nugget*. Money rather than supplies is needed. Many men will be brought out on the *Bear* and other steamers, and the smaller number to feed will render the stocks sufficient, but with one-third to one-half the assessed valuation of the city gone, schools must be closed unless assistance be forthcoming, and many will have no money with which to buy unless work can be furnished.

IRIDOSMINE is one of the rare metals concerning which so little is known that every note of its occurrence becomes important. In Mr. C. B. Horwood's article of this week will be found some notes on its presence in the Rand bankets. Fuller details were given by Mr. Horwood in a paper read before the Geological Society of South Africa in May of last year and published in volume XV of the *Transactions* of that lively society. We printed a brief abstract of this, taken from *Chemical News*, in our issue of September 27 last.

STRAIGHT thinking on industrial and political topics is sufficiently rare to warrant notice, and we commend to our readers the address delivered before the American Mining Congress by Mr. C. R. Van Hise, the militant geologist who is president of the University of Wisconsin. He is right when he says that it is profoundly immoral when the law officers of the government must prosecute one set of offenders against anti-trust laws and shut their eyes to the offenses of others. Recognition of the facts of the situation is the first requisitum to the finding of a remedy.

AFTER successfully combating the yellow fever and malaria in Panama, Col. William C. Gorgas has been called to the Transvaal to conduct an investigation of the diseases peculiar to the mining industry of that region and to devise, if possible, some remedy for those conditions which have been responsible for the high death-rate among the miners on the Rand. While the mosquito has no part in pneumonia or phthisis, it is to be hoped that the cause of these dreaded diseases may be eradicated, and we know of no one more eminently fitted for this humanitarian undertaking than Colonel Gorgas.

Immigrants and Mines

In the first of what promises to be a most interesting series of articles on 'The Old World in the New', Mr. Edward Alsworth Ross writes in the November *Century* of the effect upon industrial and social conditions in the United States produced by the rapid influx of untrained laborers from eastern Europe and western Asia. He points out that this is a movement that is artificially stimulated; that the steamship companies, largely foreign owned, have been engaged in a great hunt for emigrants for the sake of the passage money; and he estimates that in 1908 and 1909 the money paid to these companies and to the railroads by incoming and outgoing emigrants amounted to \$75,000,000. He believes that manufacturing in this country has been overstimulated at the expense of American laboring men. Without denying that there is much to be said from that point of view, and without attempting to settle off hand the problems of immigration in this country, we doubt the correctness of Mr. Ross' deductions, at least as regards mining.

The "hejira of the English-speaking soft-coal miners" is cited "as showing what must happen when low-standard men undercut high-standard men." According to Mr. Ross, "the miners of Pennsylvania and West Virginia, 'finding their unions wrecked and their lot growing worse under the floods of men from southern and eastern Europe, migrated in great numbers to the Middle West and the Southwest. But of late the coalfields of the Middle West have been invaded by multitudes of Italians, Croats, Poles, and Lithuanians, so that even here American and Americanized miners have their backs to the wall.' These 'displaced trade-unionists' are said to have gone on 'to make their last stand in the mines of New Mexico and Colorado.' As a matter of fact, the coal miners never were organized in West Virginia until recently, and the United Mine Workers is dominant in Pennsylvania today, despite the influx of Slavs.

In another place he relates an instance of how American miners, earning \$2.75 per day, in one of the copper mines of the Southwest, were abruptly displaced by a trainload of raw emigrants at \$1.50 to \$2 per day, while for the Americans there was nothing to do but to "go down the road." The "Iliad of the woes of these displaced workmen," he says, "has never been sung," and by implication the pioneer American miner has become a "hobo." We strongly dissent from this conclusion, and we believe that if Mr. Ross will follow some of those men "down the road," he will quickly learn that their fate has not been so hard as he evidently thinks.

It is entirely true, as implied, that twenty years ago the coal mines of the Middle West were manned almost exclusively by English-speaking miners. It is also true that the majority of the men now in these mines are recent emigrants of the type Mr. Ross describes. It is to be remembered, though, that the output and the total number of men employed has, roughly, been doubled. In 1900, to take the year Mr. Ross has used, Indiana produced 6,484,-

000 tons; Illinois, 25,767,981; Iowa, 5,202,939. In 1911 the corresponding outputs were 14,201,355 tons, 53,679,118, and 7,331,684. The output per man has not changed greatly, and nearly 40,000 new men have been needed in the Illinois mines alone. This is but illustrative of what has taken place in all branches of mining and metallurgy. Mr. Ross says that "if the supply of raw Slavs were cut off, the standard and status of the laborers would rise, and the Americans would come into the industry." From where would they come? And from where would the extra men needed in the last ten years have come if there had been no emigrants? Picture the result in almost any community of excluding the new workmen of the last ten years. It is true that in the coal-mining towns the visitor sees squalor and misery. Bituminous coal-mining in many states is necessarily a seasonal industry. The mines are idle 100 to 200 days in the year. This idle time comes in the summer when less coal is burned, for it must be remembered that much of our coal will not stand storage. The American and English-speaking miner of earlier times used these summer days for cultivating gardens or for farm work. Many a one graduated into a small landed proprietor. The Slav finds his income from a half year's work so much larger than that to which he has been accustomed, and the new freedom so alluring, that he idles away the summer days. Hence the misery and the low standard of living; but his children will not be content with that, for children are keenly sensitive to the comment of their school-fellows.

It is not true, so far as our experience goes, that the English-speaking, and presumably more competent, miner has been injured by the influx of the foreigners. The large number of men employed has made room for more bosses, especially since the untrained laborers require more supervision than did the old style workman. The introduction of machinery has made places for others. Still others have it is true "gone West," but we who live in the West do not look upon that as any terrible fate, and the old miners that we know in the West are doing fairly well. The men who have drifted out of mining are working at something at which they make more money—witness the Irish saloonkeepers at La Salle, Illinois—or are working under conditions of greater personal independence. Many an active lessee in Western gold mines is a former coal miner, and many a well-fixed Iowa farmer once dug coal. A large number of the displaced iron miners of Minnesota, of whom Mr. Ross speaks, will be found comfortable and happy in the copper mines of the Southwest to which they were attracted, not forced, by the good pay, better climate, and the lure of the unknown.

It will be remembered that twenty years ago western Missouri and eastern Kansas were dotted with small zinc smelters. These were largely manned with English-speaking workmen. When natural gas was found and larger plants were built, these men formed the nuclei of each force and additional workmen were found locally. A few years ago, as the gas pressure fell, these plants began to close and new coal-fired furnaces were built in Illinois. A man trained in zinc metallurgy is a valu-

able workman, a fact thoroughly appreciated by the managers of these enterprises, and large inducements were offered to the old men to go with the technical staffs to the new field. In a specific case that we have in mind comfortable houses were built within street-car distance of an excellent city, and practically the whole force was moved over from Kansas. In less than two years nearly all of the men had drifted back to their old home, where they had friends, connections, and other interests. There was no dispute as to wages, but the bulk of the men owned some little property in Kansas, and besides, as the Irish washer-lady said, "I'd ruther do as I'd ruther." The manager of the zinc plant could not get new men from the Illinois farms for the reason that land in central Illinois earns interest on \$200 to \$400 per acre. As a result, that plant is now run with Slav labor, and the manager had to give up use of the top row of retorts because the strong, heavy Slav cannot fire them properly, though the lighter American had done so for years. We believe this is a fairly typical case of "displacement" of American labor, and we see in it nothing to discourage the American. Just at present times are dull in mining, as occasionally happens. Men are out of work at many places, but if there is any great reserve into which a mine manager can "dip at will," we do not know of it. Under normal conditions the miners who are persistently out of work are those who have personal characteristics which militate against their holding jobs, or are reputed ore-thieves. In mining, low-priced men are not substituted for high-priced ones to any large extent, because the world-wide experience of American mining engineers has proved that, with rare exceptions, the substitution results in trouble rather than economy. The same engineer often has charge of mines in a half dozen countries or districts and under as many different wage scales, and it takes but the study of a few company reports to show that the cost per ton is not measured by day's wage. Any experienced mine manager would rather have a force of 8-hour, \$3 men, than of 10-hour, \$2 men, provided the men put their minds on their work as is the happy characteristic of the American working man. Immigration causes problems serious enough in all conscience, but the "displaced" American miner is not asking sympathy.

The Rand Banket

By T. A. RICKARD

In presenting these articles the editor has found one technical difficulty: that of terminology. As is generally known, the pioneers of the Witwatersrand adopted several Australian terms and called their lodes 'reefs.' Finding a type of ore with which previously they were unfamiliar, they borrowed a Dutch word, and called it 'banket.' Further, being more eager to make money than to preserve the English language, they spoke of their workings as 'drives,' not drifts; they sought 'high values,' meaning ore having a high assay-value; they delved in search of 'good gold,' not doubting that all gold was good, but desiring gold in goodly proportion. Even educated engineers borrowed the language of

trammers and timber-men, so that ore was described as 'payable,' instead of profitable; waste became 'mullock;' shale was loosely labeled 'slate;' and the locality itself became "these fields."

'Banket' is a genuine addition to the English language. It is the word used by the Dutch for almond eake; it is significant and full of local color. A 'banket' stands for a conglomerate containing sufficient gold, or any other valuable metal, to be exploited as an ore deposit. 'Banket' in its etymology harks back to the Dutch domination of the Transvaal, and to the great series of gold-bearing conglomerates or almond-rocks associated with the modern mining development of South Africa. It is convenient to use 'conglomerate' in petrography, and 'banket' in economic geology. Every banket must be a conglomerate, but not many conglomerates are bankets. By giving precision of meaning to words, and by setting aside special words for special duties, we gain accuracy of expression.

Another useful South African addition to technical English is 'deep-level.' The first properties developed from the surface were known as 'outcrop' mines; these had no extralateral rights, and were estopped from trespassing beyond their side-lines projected vertically downward. The next mine on the dip of the lode became known as the 'deep-level' mine or 'deep' of the corresponding outcrop property; thus the Ferreira Deep exploits the ore beyond and below the limits of the Ferreira. In the same way the Tamarack, in the Lake Superior copper region, is the 'deep' or 'deep-level' of the Calumet & Hecla. On the other hand, the habit of writers on Rand geology to use such terms as 'reefs,' 'reef-matter,' 'values,' and the like, tends to obscure the basic economic feature, namely, that the conglomerate is 'ore.' We have read articles on the Witwatersrand in which the words 'ore' and 'lode' were absent to such a degree as to warrant the reader in forgetting, or failing to apprehend, that the deposits under discussion were the object of profitable industry. The word 'reef' was introduced into mining by the sailors and stewards who left their ships to participate in the rush to Ballarat and Bendigo in 1851. To them a rock projecting above the water was a reef, and when they saw outcrops of quartz they likened them to one of the perils of navigation. However descriptive the term may be when applied to an orebody emerging above the plain, it is wholly a misnomer for lodes that have no outcrop and for orebodies found far below the surface. Any significance that 'reef' may have in mining is entirely lost when applied to ore discovered or intersected far from sunlight, especially when, as in Rhodesia, it may be a mass either lenticular or without definable shape. Fortunately, it is a local term peculiar to Australia and South Africa. In other equally important mining regions it is not legal tender, but one of the many spurious verbal coinages of illiteracy. Nor is it required. We have 'lode' and 'vein.' Indeed, the use of 'reef' has tended to obscure the fact that the ore deposits of the Witwatersrand or 'white waters range' are not unique, except in their persistence. Beds of conglomerate containing gold have been found elsewhere in many regions. Gold is found

enriching rocks of every kind, both crystalline and elastic. The deposits exploited in the environs of Johannesburg are lodes as much as, and no less than, those of other celebrated mining districts. A 'lode' is a deposit having such continuity of structure as will lead a miner to the discovery of ore. The word comes from the Anglo-Saxon word *lad*, from *lithan*, to go, and is related to *leadan*, to lead, another derivative from *lithan*. 'Vein' may not fitly describe the bed of conglomerate, because it is not typically a ramifying fracture or fissure filled or followed by ore, but a seam of banket is certainly more nearly a bedded vein than a 'reef,' in so far as these terms have any precise meaning. 'Drive' is an error when used as a synonym for 'drift.' The miner drives his working, which results in a 'drift.' 'Mullock' is a wretched Australian vulgarism that only obscures meaning. It stands for waste rock, the reject from ore. When the Australian sailors and shepherds introduced 'good gold,' 'poor gold,' 'rich gold,' and so forth, to express the relative richness of their ore, they garbled their speech. No need arises for educated men to adopt such illiteracies. Thus also 'values,' with 'high' and 'low values,' was originally an abbreviation for ore valuable by reason of its metallic contents. As now used it is only a misleading colloquialism. To seek values in a mine is comparable to the pursuit of a quadratic equation in an automobile. Whatever excuse there may be for carelessness in casual talk, there is none for the introduction and use of such phrases in scientific writing. Again we say that accuracy of thought is fostered by precision in the use of the vehicle of thought, namely, language, whereby we transfer ideas from one to the other.

'Shale' and 'slate' are different rocks. No educated engineer should use one term for the other. A 'shale' is fissile along its lamination, which is its line of original deposit. A 'slate' is fissile along lines independent of the stratification and usually at a high angle with it. 'Payable' is a mere vulgarism. Ore does not 'pay' nor is it able to pay; it yields a profit; it is profitable. Even if we overlook the use of an intransitive verb as if it were transitive, it remains a fact that ore that only 'pays,' that is, meets the expense of exploitation, has no economic worth. To have that it must yield a profit; it must be profitable. As for 'fields,' this also is scarcely worthy of castigation. It is bucolic. As an abbreviation from goldfields, it exemplifies the hankering for an inexpressive plural, the squandering of a useful inflection, and the popular fancy for the abstract as against the concrete. These matters of terminology seem petty, but they are not. Apart from the clarification of thought by the filtering of language, it is worthy of remembrance that the English language is the common heritage not of the Briton, the American, the Australian, or the Afriander, each and severally, but of the 400 millions of English-speaking peoples on both sides of the equator and in both hemispheres. All of us share a priceless inheritance, our common literature, and it should be our aim not to curtail the usefulness of it, especially in technical science, by the employment of terms half understood locally and misunderstood everywhere else.

An Excursion to North American Smelting Works

By FERDINAND HEBERLEIN

*In connection with my visit to the eighth International Congress of Applied Chemistry held in Washington and New York, I made a trip through the most important metallurgical districts of the United States of America and Mexico. I therefore shall gladly comply with your request to tell my German colleagues of my traveling impressions. With the limited time placed at my disposal today, a detailed description of operations of the processes and apparatus used will be precluded. You are very likely fully acquainted with these from the literature of the subject. I will therefore restrict my remarks, by calling attention to those particulars of practice in the works of the Western Hemisphere that most impress metallurgists familiar with European conditions. The general, as well as the mining and metallurgical conditions in particular, are so radically different in the two hemispheres, that the development of the smelting industry as well as the requirements demanded abroad in the solution of certain problems, show a decided departure from our practice. America's metallurgical industry is hardly fifty years old, and, compared with the centuries old European metallurgical and mining industries, is just at the beginning of its development.

Conditions in the Eastern States

In the Eastern states the general conditions resemble or rather remind us vividly of Europe. The density of population and wage conditions related therewith, and the existence of large chemical and mechanical industries are very much the same. These as producers and consumers in the metallurgical industries play an important part, but even in the East, wages as well as the cost of living are appreciably higher, and the price of coal lower, than with us. For instance, at Pittsburgh, iron works can buy excellent coal for 3 to 4 mk. (0.75 to \$1) per ton, and can therefore easily make coke for about 8 mk. per ton. Workmen earn per shift 12 to 16 mk. (\$3 to \$4). Whereas here in Europe, feeding of our smelting works depends to a great extent on the working of relatively small ore deposits and on the receipt of smelting products from remote parts of the world, in America we have to deal primarily with immense ore deposits which have commensurably extensive mine surface plants and reduction works. The American mine and metallurgical industries are controlled by companies which command very large capital, have excellent organization, and show a commendable business aggressiveness. That smaller enterprises are taken advantage of and hurt in business by these giant concerns is natural and may now and then have been the case, but on the other hand it must be admitted that without the resources of these powerful companies many a mine and smelter could not be operated or worked with commercial success. I also gained the impression

that even the most powerful companies, if for no other reason than not to violate the anti-trust laws, let the small ones live and recognize their right to existence. For the progress of the science of mining and metallurgy, healthy competition can only be welcome.

Smelter By-products

Excepting those in the Eastern states, the smelting works are remote from centres of chemical trade and consumption. It is thus naturally brought about that certain principal constituents of ore and by-products cannot be utilized now as in Europe. For instance, the utilization of enormous quantities of sulphur from the sulphides in the ore cannot be thought of in many cases, notwithstanding the fact that the quantities of sulphurous acid gases escaping into the air are in places enormous. On my trips I visited works in which so much sulphur in the form of sulphur dioxide went into the air that 1000 tons of sulphuric acid could have easily been produced per day. The escape of these large quantities of SO₂ gases can, however, not be avoided unless the mining and smelting operations are suspended. As in those districts the mining industry by far outweighs in importance all other industries, it has the first right to free development and operation. After the mines have once been exhausted the land will undoubtedly be made available again for agricultural purposes. Naturally, even in such works not only the operators but also the inhabitants have to be protected from damage of the sulphur dioxide gas. In smelting works which have been adapted to acid manufacture, as at Ducktown, Tennessee, the sulphur is retained and utilized. In these works 550 tons 60°B. sulphuric acid is made daily from the gases of the (copper) pyrite blast-furnaces which is used with such great commercial success in the preparation of superphosphate (acid phosphate) that the above named works are said to produce copper indirectly at the lowest cost. What I have said regarding the extensive non-use of the sulphur applies also to other material such as low-grade arsenious ore, and to zinc and other ores which cannot stand high freight charges. While therefore, we cannot criticize the prevalent but justified non-utilization of the sulphur and of other materials, there still exists in other operations, as for instance in the coking of coals, great wastes through non-recovery and non-utilization of the by-products. During the excursion of the members of the eighth International Congress on Monongahela river near Pittsburgh, the leader called our attention to the fact that the steamer had just passed 2500 beehive coke ovens and that not only the gases but even a portion of the carbon is lost in the coking process. Of late, however, modern coke oven installations are being rapidly adopted in the United States, principally the Otto, Koppers, and Solvay types. I was very much surprised to find that large copper and lead smelting works which treat daily several thousand tons of ore and therefore have a daily coke consumption of more than 200

*Address delivered at the second general session of the Gesellschaft Deutscher Metallhütten und Bergleute, Aachen, July 6; printed in *Metall und Erz* and translated by Herbert Haas.

tons, have not yet started to erect their coking plants at the smelting works. Even if the benzol, ammonia, etc., were not recovered, the utilization of the gas and tar would at any rate permit of cheap production of steam power.

While many smelters are situated at the mines, those which entirely or at least partly depend on custom ore are built at the junction of a number of railroad systems. This is not only done to facilitate the shipment of ores but to secure better freight rates from competing railroad companies which here are not government owned. On long hauls these companies make lower rates than on short ones so that, for instance, a smelter in Missouri is able to compete with works in Colorado, in securing ore from Montana, as far as freight costs are concerned. Conspicuous to us Europeans is the extremely limited use of waterways for the transportation of ore in bulk and coal. This is particularly due to fluctuating water and bad shipping conditions on even the largest rivers, as the Mississippi, Ohio, and Missouri, and partly to the action of the powerful railroad companies. These are interested in preventing the development of the cheap water transportation. In the matter of water transportation, we Europeans are no doubt far ahead of Americans.

Tonnage of Ore Handled

The quantities of ore which are handled in American lead and copper smelting works are materially greater than those in European works. The smallest lead smelter which I inspected still puts through very much more ore than the largest European smelter of which I know. The treatment of such vast quantities of material has forced the American metallurgical engineers to give to the conveying and handling of materials as much consideration as to the metallurgical part of the work itself. For this reason there are generally built very complete installations for cheap conveying, loading, crushing, and transporting of the ore and fluxes. The railroad cars have the usual loading capacity of 50 tons. The upper part of these cars is made of sheet steel and nearly all have automatic unloading arrangements. For the transportation of materials in and around the works electric locomotives, large traveling cranes, and particularly belt conveyors and similar contrivances are extensively employed. In this respect we can learn a great deal from the Americans.

Methods of Handling Molten Material

Fluid materials such as slag, matte, molten lead, and copper are stored in various sizes of receptacles in the form of ladles or slag pots and are transported by rapidly moving locomotives or traveling cranes. The size of ladles for copper matte are of course, adapted to the capacity of the converters, but frequently they hold 30 tons, and slag pots 5 to 10 tons. In one of the works we even saw one of 30 tons capacity, but the gentlemen operating this plant themselves thought this was somewhat too large. The slag pots are usually emptied by piercing the refractory hole, which is about 25 cm. (10 in.) above the rim of the pot, from the inside through the refractory. Beds of slag are also removed from the outside. The slag shells, with

that matte which has accumulated at the deepest point, are re-smelted, whereas the fluid slag flows over the slag dump. In places both the slag and matte are granulated by water and sluiced by it to their respective destinations. The molten lead of the blast-furnaces is tapped intermittently through the automatic (siphon) tap into a lead kettle running on wheels and this is run to and poured into large collecting kettles to remove the lead dross. To remove the molten lead from one kettle to another one, or to refining furnaces, centrifugal pumps made of iron are now being used. These are suspended in the lead kettles and driven by electric motors. Such a pump can lift five tons per minute to a height of three metres (about 10 feet).

In nearly all smelters there are air-compressor plants and compressed air pipe-lines are found in all the buildings and are thus handy for the great variety of uses. For instance, air hammers are used to break up materials and air lifts are connected with these air lines. The lifts serve to raise smaller loads such as lead and copper bars and blocks out of the mold, to ears or into the furnaces. Even the workmen are elevated in high buildings. In a Colorado ore-dressing and sampling plant which treats daily 1000 tons, a rapidly moving endless canvas elevator running through all four stories of the building is used for elevating men. On a strong vertical canvas belt are fastened handles and steps. In all other respects it is like the usual bucket elevator and in constant operation. The workman who, for instance, wants to get from the highest story to the lowest one, takes hold of the handles, steps upon one of the supports, and immediately disappears into an opening in the floor.

Prime Movers

Reciprocating steam engines are generally used as prime movers in the operation of smelting and ore-dressing plants, whereas we here in Germany and in other European countries have replaced the older types of machinery with more modern sets, especially with large units of steam turbines. I found that in America, especially in the more remote metallurgical plants, a large number of steam engines of older construction and in small units are still extensively used. For blowing engines Green blowers are generally used and the latter are usually direct connected to vertical steam engines. Special attention is given in many works to the air consumption of each furnace. In the works of the Cia. Minera de Peñoles at Mapimi (Durango), Mexico, logs of the air consumption per ton of charge smelted have been kept for years. With these uninterrupted reports, which make comparison possible, not only defects in the air mains, and the tuyere pipes were discovered and thus leaks stopped, but in time the record system made it possible to reduce materially the cost of the air used per ton of smelting. I am of the opinion that in this direction we should keep very careful and constant records in European works.

A peculiarity of the works situated at high altitudes in the Rocky Mountain mining districts is the so-called thawing house, its use being made necessary by the cold climate. These are long narrow houses in which 8 to 10 railroad cars can be

placed with frozen ore (during winter); these thawing houses have usually double walls and double roof and are either heated by steam coils or by a long centrally placed masonry or brick flue fired direct with coal. In other places small coke stoves are placed in the railroad ears to thaw the ore. The ores in stock houses naturally have to be heated also. Of great importance in American reduction works are the sampling mills on account of large quantities of ore that are daily received. The sampling is usually done by machinery where a large quantity of ore has to be sampled, or where a large number and a great variety of lots, especially small ones, have to be sampled, this work is usually done by hand. The mechanical sampling mill is connected directly with the unloading and coarse-crushing plant in which all large pieces of ore are first broken. The crushers are followed by Vezin or Snyder samplers and smaller crushers. Rolls and samplers gradually reduce the ore down to a definite size. A model plant is that of the Golden Cycle mill in the Cripple Creek district near Colorado Springs.

Concerning the modern metallurgical laboratories, I must say that these as a rule are very well equipped and that electricity is very extensively used for heating muffle and fusion furnaces for the preparation and heating of distilled water, for sand baths, dryers, and similar uses. It is the usual intention to keep the laboratories as free as possible from dust producing ovens and furnaces and to reduce as much as possible the manual labor. I wish to add that the lead in ores as well as in the slag is almost exclusively determined wet by titration. The silver, however, is determined dry by scorification; copper by titration or electrolytically.

Fluxing Materials

In working the different ores, the use of fluxing materials containing no valuable metal constituents is as much as possible avoided. The preparation of a uniform furnace mixtures is therefore for American smelters even of greater importance than for us. In many cases this is not difficult, as many works receive large quantities of ore of uniform composition. More difficult is the mixing of ores in works whose operations depend on fluctuating receipts of custom ore. To insure uniform operations, large stocks and ore beds containing the different classes of ore are prepared. In the very modern lead-copper smelting works at Tooele, Utah, the different ores are stored in a large number of separate steel bins built in a row. Beneath each bin gate a loose sheet-steel hopper is suspended which is connected with an automatic scale. The desired quantity of ore or flux is emptied into these hoppers. An electrically operated charge-car running beneath these hoppers receives the load, the car operator in emptying the hopper distributing the ore over the entire car bed, which is long but narrow. After all constituents have thus been well mixed and loaded into the car it is run to the roasting furnaces or the charge-floor of the blast-furnaces. The doors, which usually keep the furnace top closed, are opened by a system of levers by the car operator, the bottom-dropping charge-car empties its contents, the furnace doors are closed again, and the car run back. With this system, two

men per shift can deliver the entire stock for one blast-furnace of 250 tons daily capacity. The arrangement here discussed presupposes a terraced smelting plant. In works built on level ground the smelting stock is usually delivered by inclined railways. In different works they use the Messiter system for the preparation of uniform stock mixtures. Large level beds are so laid out that the conveyors fitted with automatic trippers distribute the material evenly over the bin. The large copper smelting works at Douglas, Arizona, has the ore and flux delivered into large and long pits which are about 20 ft. wide and 13 deep. The different materials are brought to one side of the pits in railroad cars and dumped in successive layers into the pit. A steam-shovel running on a track in the bottom of the pit lifts the ore into rather large charge-cars running on a track on the other side which take it to the charge-floor of the blast-furnace. The final charges are dumped direct into the blast-furnace, no shoveling being done.

Roasting Apparatus

Regarding the roasting apparatus used in the preliminary preparation of the lead, copper, and zinc, the following may be said. The historical Freiberg reverberatory roasting furnaces rabbled by hand have nearly everywhere become extinct. I found them in operation only in two smelters in Mexico and Colorado, and here they will hardly remain much longer in operation. The Bruckner cylinder of old, once generally used, has disappeared. In its place, especially in works that treat lead and mixed ores and matte, the Huntington-Heberlein (circular hearth) furnaces with the H. & H. converters are used. In a lead smelter in the Missouri district the pure lead ore in dolomitic gangue used to be worked by the Savelsberg process. The roasting plants using the H. & H. process are usually built along different lines in the United States from those adopted in Europe and Australia. While we generally support the roasting pots some distance above the ground and empty the contents by tilting them, the so-called 'H. & H. converters' are usually embedded in the roasting floor. The converter, which holds 10 to 12 tons of roasting material, is covered with a hood having a gas out-take connected with the main flue and stack. A traveling crane is used to empty these converters; first the hood is removed, then the pot is moved to another part of the building, lifted high, and tipped. The large lumps remaining are broken to head size in large breakers. The empty pot is placed by the crane in front of an H. & H. round hearth furnace and the grate is first covered with about 1 ft. of hot pre-roasted material. Then about 3 ft. of cold wet raw ore with about 20% S and 10 to 15% Pb is added, and the converter is taken back to the blowing stand. The roasting is started by turning on the blast, and more cold ore is added later according to requirements. The heat developed in the H. & H. converter is greater than that generated with Dwight-Lloyd apparatus. It is therefore possible to roast raw pyrite with a smaller sulphur content. Should the heat generated by too large a quantity of sulphur be too great, then the excess sulphur can be eliminated by a preliminary roast, or can be reduced by the

addition of ore free of sulphur, roasted ores, limestone, or other materials. Even refractory ores that do not smelt easily can be sintered in the H. & H. converter by this practice. When roasting the pure lead ore of the Missouri district, sand or fluxes rich in iron and lime would be added before smelting, as is customary in European and Australian practice, which would make necessary only one reduction of the lead by blast-furnace smelting. This would in a way be a re-smelting of the already slagged constituents. The Americans, however, do not care to subject the lead ores to the double treatment in the H. & H. round hearth furnace and converters, or the Dwight-Lloyd apparatus, but prefer to blow the raw ore without any fluxes or additions direct. Therefore iron and limestone fluxes have to be added to the blast-furnace charge. Roasting costs therefore less in American works, but the work is inferior to ours. In a number of works the continuously operating Dwight-Lloyd apparatus is being adopted.

Furnaces

For free burning ores, such as pyrites, Herreshoff, Wedge, and Klepetko furnaces are almost exclusively used. Hand operated kilns or furnaces for roasting blende I have found nowhere on my trip. For the latter work the well known Hegeler furnace is extensively used in the United States, even when the sulphur in the blende is not utilized, which is generally the case. In addition to the Hegeler furnaces, a number of Zellweger and Cappeau furnaces are still used. The latter is a sort of Ropp furnace, altered for the mechanical roasting of blende; these two types are not muffle furnaces, but are direct fired.

In copper reverberatory smelting practice it is desirable that the roasted ore or concentrate be delivered to the furnace as hot as possible. The calcine from Herreshoff and similar furnaces is therefore delivered in hopper bottom cars to the charge hoppers over the reverberatory furnace in a red-hot condition. Ores which have to be treated in these furnaces are first thoroughly dried, which is done in mechanical dryers. In one works a Wedge dryer is installed which daily had to dry and heat to 350°C. some 160 tons of copper concentrate containing 7% moisture.

As has been previously explained, fuels are comparatively cheap in most of the American metallurgical works. The natural result is that, on the whole, less care is exercised in utilizing the fuels as efficiently as here. Even zinc furnaces are frequently operated without regenerators or recuperators. In many localities natural gas can still be obtained at relatively low prices, as for instance in Pennsylvania, Kansas, Oklahoma, etc. The gas contains about 94% hydrocarbons (almost entirely methane), about 1% CO, and 4% N, and costs about ½ pf. (1½c.) per cubic metre. About 600 cubic metres of gas is equivalent in fuel value to about 1000 kg. of coal of good quality, which would correspond to a cost of 3 mk. (75c.) per ton of coal. A special advantage of the natural gas lies in the circumstance that the installation cost for furnaces is very low, another that of ashes and dust being entirely absent. With the daily increasingly large natural-gas consumption for the lighting of cities,

for generating steam in power-plants, etc., the gas pressure, as well as the gas volume, is decreasing rapidly, so that metallurgical works depending on natural gas for fuel have to be amortized in a short time. In a few states, as California, Texas, and Utah, petroleum is used as fuel in metallurgical furnaces, and the experience that has so far been had with oil firing has been extraordinarily favorable, even in places where the oil is not merely chosen as a fuel by reason of its cheapness. Neglecting cleanness in operation, the ease of transportation to the works and around them, and the facile handling of the oil, the flame can be regulated very easily, both as regards degree of temperature as well as oxidizing and reducing action. When it is remembered that a large copper reverberatory furnace consumes daily 80 tons of coal, of which about 16 tons (20%) is rejected in the ashes, it is easily realized what may be saved in transportation costs alone by substituting oil for coal firing. One of the large reverberatory furnaces about 6 m. wide and 33 m. long (20 by 110 ft.) consumes, with a daily smelting capacity of 300 to 400 tons of ore, about 45 to 50 tons of oil. The waste gases escaping at the end of the furnace pass under a water-tube boiler and generate sufficient steam for 600 hp. Installations using pulverized coal for firing are comparatively rare, very likely due to their high first cost and the accumulation of the ashes on top of the metal and slag bath, which makes these not only viscous but dirty.

Metallurgy of Copper

Without a doubt, the metallurgy of copper is a field of which the American metallurgists have become the masters, and nowhere else can the most modernly equipped copper-smelting works be better studied than in North America. The wonderful development of this industry during the last ten years is based on the most varied ore deposits, and the great variety of working conditions has brought the metallurgy of copper to a great degree of development. Not only the recovery of the metal itself has steadily been increased, but the costs of production have been constantly decreased, so that today ores are beneficiated which 15 years ago nobody thought of working. The great perfection of the copper-smelting processes has to a great degree limited the use of the wet processes, so that today dry methods are preferred to wet processes wherever possible. From the literature of the last few years you will be familiar with the apparatus and furnaces used in copper smelting, so that I can restrict my remarks to the principles of present-day copper metallurgy.

As a general thing, the sulphide ores are treated separately according to their size. Coarse ores larger than ¾ in. are sent direct to the blast-furnaces and are smelted pyritically wherever this is permissible, to a 40 to 45% matte; about 75% sulphur is burned in this operation and passes off as SO₂ into the air or into the sulphuric acid chambers. The matte is collected in the forehearth, and the slag, containing about 0.4% Cu, flows into the slag pots, which are emptied on the slag dump. The fine sulphides below ¾ in. are roasted if high in

sulphur in the manner presently described, or if they contain but a small portion of sulphur, are charged direct with the hot calcine into the reverberatories. These modern large reverberatories are at present very much favored, especially in localities where cheap fuel oil is obtainable.

Copper Smelter Products

The products are here a slag with about 0.4% copper and a matte with about 40% copper. The latter, as well as the matte from the forehearth of the shaft-furnaces, is tapped into ladles and poured into the converters with the addition of silicious copper ores as flux. By Bessemerizing, a blister copper with about 96% Cu and varying gold and silver content is obtained, which is cast by means of ladles and casting machines into bars. Of late years, basic converters have replaced the acid converters. On account of their greater durability they have been rapidly adopted. While with the acid-lined converter only three charges could be blown, and at best only 150 tons of copper produced, it is possible to produce as much as 6000 tons of blister copper in similar converters with basic lining. Of late, experiments have been made in different works in blowing leady copper matte with low copper content in basic-lined converters. Technically, these trials are said to have been entirely successful, but there is still much difference of opinion among metallurgists as to whether the process is also a commercial success.

The blister copper is further treated by electrolysis in refineries which are principally situated around New York. The usual process is the multiple system, the series system being rather the exception. There are works with a daily capacity of 500 tons electrolytic copper. A number of refineries have wire bar furnaces which handle 300 tons of copper in 24 hours, while the capacity of copper blast-furnaces and reverberatory furnaces for smelting ore are 800 tons and 500 tons per day, respectively. Neglecting the Mansfeld works, which handle by far the largest tonnage of copper ore in Europe, a single blast-furnace of that size would nearly suffice to put through all the copper ore that is smelted in one day in Europe.

The lead smelting works of North America can be classed into two groups, namely, those that treat rich lead ores with more than 65% lead, and those that smelt ores low in lead with silver-gold ores low in copper. The works treating high-grade lead ores are nearly all situated in the Missouri district and produce about 130,000 tons of merchant lead per year. From the second class are produced some 250,000 tons of lead which would correspond to about 1.80 to two million tons of furnace charge. The Missouri ores contain so little silver that the merchant lead contains only about 60 gr. (about 2 oz.) per ton. It is therefore not desilverized, but principally is refined by blowing dry steam and air through it. Small amounts of copper in addition to the silver remain, therefore, in this lead, which is, as a result, not available for the making of white lead, but is used for rolling. The rich lead ores are either pre-roasted in the Scotch hearth and 50% of the lead in this operation eliminated,

and then smelted in the blast-furnace, or they are roasted partly in the H. & H. round-hearth furnace or in the H. & H. converter, or direct with the addition of silica and a small amount of flue dust in the Dwight-Lloyd apparatus, after which follows reduction in the shaft furnace. The shaft furnaces are almost exclusively rectangular and measure at the tuyeres from 36 to 42 in. wide by 96 by 144 in. long. The number of tuyeres is 12 to 18, with a nozzle of about 4 in. The blast varies from 120 to 160 cm. water column. The coke consumption is usually low, about 12% of the charge, in which, however, is not included any slag returned. Notwithstanding the low copper content and the richness of the Missouri ore, the matte fall as well as the coke consumption are high according to our ideas. It is my opinion that this is largely due to the difference in the work of roasting compared with that in America. The low-grade lead ores up to about 4½% S are sent direct to the blast-furnace; with greater sulphur content they are roasted like the richer ore, either by the H & H process or with the Dwight-Lloyd apparatus, and are then sent to the blast-furnace. Blast-furnace smelting, as a general rule, is so conducted that the charge does not contain less than 10 or 12% lead, and that a good extraction of gold and silver is only likely when lead bullion and matte fall combined amount to 18% of the weight of the charge. The matte is collected in a forehearth and the slag flows over into slag pots to be desulphurized. As a rule, the matte does not contain more than 10 or 12% copper. With higher copper content, difficulties are sure to be experienced with the siphon taps. The first matte is crushed, roasted, and sintered in the above-named apparatus, and then treated in the blast-furnace to a 40 to 45% matte, which is then sent to the copper smelter.

The lead bullion of the many different lead smelters in the United States is desilverized in a few large lead-refining plants where the methods are very much the same as with us. Of late oil fuel has been largely adopted for smelting, refining, and zinc distillation. To remove the zinc crusts, Howard presses are used almost exclusively, and the Howard mixer is also used to stir the zinc into the lead bullion.

Zinc Smelters

Zinc smelters have been erected in the United States at points where either cheap coal or a natural gas can be had. As already noted, the sulphur from the blende is not utilized even where roasting is conducted in the Hegeler, a muffle furnace. The Zellweger furnaces are about 35 m. long and have a maximum height between roof and hearth of less than 7 ft. The capacity per 24 hr. is about 30 tons of raw blende, with a gas consumption of about 600,000 cu. ft., which is approximately equal in heating value to 30 tons of coal or 100% of the weight of the ore. The roasting is nevertheless cheap and good, and metal losses are small. Considerably less gas is used with the Cappeau furnace, of which the height of hearth in centre is 3 ft. 7 in. In this furnace 25 tons of blende requires about 300,000 cu. ft. of gas, equal to 15 tons of

coal; corresponding to about 60% of the weight of the ore.

Distilling Furnaces

The zinc distilling furnaces heated with natural gas, as well as the Hegeler furnaces heated with producer gas, are fired without regenerator or recuperative systems, but have large capacities, up to 18,000 kg. (19,836 short tons) of ore, with 860 retorts. A peculiarity of these furnaces is the scarcity of prolongs; the condensers, partly extending out of the furnace, being fairly cool. The production of zinc dust is practically nil. The cleaning of the retorts is generally done by spraying water or steam into them, followed by the scraping off of slag that may adhere to the walls. Usually each furnace is in its own building. The fuel consumption of a distilling furnace is, of course, considerable and may be placed at about 180% of the weight of the roasted blende.

Among wet processes, cyanidation of gold and silver ores is the most important. Frequently amalgamation is used even when crushing the ore in cyanide solution. The ores of the Cripple Creek district which were formerly treated by the Plattner chlorination process are now cyanided, of course after the sulphur and tellurium have been removed by roasting. Even from the rich arsenical silver ores at Cobalt, the silver is extracted by a combination of amalgamation and cyanidation.

The extraction of copper by chloridizing roasting from pyrite and low-grade ores, which plays such an important part in Europe, is practised at present only in Philadelphia. A great deal was heard about copper leaching processes at the International Congress, but the future must decide the value of the interesting processes proposed. On account of the large quantities of precious metals produced yearly in the United States the parting of gold and silver is of great importance. I was somewhat surprised to see the large gold-silver refineries return from the electrolytic to the old sulphuric acid parting process. I was told that the latter permitted more rapid working, therefore lower interest losses.

The problem of flue dust precipitation has been given a great deal of attention lately in the United States and large sums have been expended upon experiments in construction. Contrary to European practice of wet concentration to condense wet as much as possible, preference is given to bag filtration, in places with automatic shaking of the bags. This works well where the gas is not too acid; the space requirements and cost of installation are, however, considerable. The flue chambers, which must be cheap to build and effective in cooling the gases, are constructed according to the catenary system. The old-style chambers originated at the Fredericks works are much liked and are said to give good results. In a number of works the Cottrell electric process of precipitation was tried, operating with a high-tension direct current. It gave especially good results with wet gases; of course, the oxidation of SO_2 to SO_3 and condensation of the latter forms no part of this particular process. Many experiments have been directed to making the sulphurous acid anhydride harmless, as large works

have been forced to suspend operations on account of fume damage. A commercial process yielding a gas low in SO_2 has not yet been perfected; the only help is to mix the SO_2 gas with air. Young wants to make concentrated SO_2 gas harmless by reducing the sulphur with hydrocarbons at high temperature in the presence of catalyzers. It seems to have been demonstrated that Young's process works well on an experimental scale with gas high in SO_2 and low in free oxygen, but it is too expensive with gases low in SO_2 .

New processes for production of potash salts from phonolites and leucites were much discussed at the congress. Of the commercial phases of these processes, I was not able to learn anything, but it is true that great efforts are being made in the United States to become independent of the German potash market. Work is also being done on the production of high-grade fertilizers from phosphate rocks without sulphuric acid treatment. An excellent fertilizer with its phosphoric acid soluble in citrate solutions, but insoluble in water, is soon to be made by burning at high temperature a mixture of phosphate and lime rock.

In regard to the hygienic arrangements of American metal works, little is to be said. While industrial safety and health laws are not so rigidly conformed to as here, the correctness of the principle is being recognized that the maximum work and effort of the workmen can only be demanded when providing as essentials for good work, lots of light and fresh air, and it is to the employer's own self-interest to provide well lighted and ventilated works.

Accounting

I wish to add a few words regarding works book-keeping and accounting. I had opportunity to look into this in a number of works and received the best of impressions. Not only labor, ore, and warehouse records are kept, but the daily reports enable the works manager to determine operating costs from day to day, which is of far-reaching value to him. In conclusion, I wish to emphasize the extent to which American metallurgy is connected with German names. Ahrend, Eiler, Fabre du Faur, Aug. Meyer, Stetefeld, Aug. Rath, Fohr, Liebenau, Albert Ahrents, O. H. Hahn, Emrich, and Huber should be particularly mentioned. These men, the majority of whom received their training at Freiberg or Clausthal, are recognized as pioneers in the American metallurgy. The conclusion of my discussion of impressions obtained in my travel can be compressed in the opinion that Americans, as far as the metallurgy of copper is concerned, are far ahead of us. Regarding the treatment of large tonnages of low-grade lead ore, a similar comparison cannot be made because we have no corresponding works in Europe, but this work also is excellently done. But in the treatment of rich lead ores, we European smelter men compare very well with our American colleagues. As far as the metallurgy of zinc is concerned, I believe that we, in the matter of quality of work, that is, in zinc recovery and coal economy, are ahead of the Americans; but thanks to the cheaper fuels many American zinc works enjoy, their costs are lower than ours.

BEAVER DREDGE, SHOWING SLUICES FOR RESOILING.

Resoiling After Dredging in California

By G. L. HURST

Although few people are aware of the fact, the resoiling of dredging ground in California has been going on for the past three years, on a property owned by the Beaver Gold Dredging Co. near Loomis and managed by N. J. Martin. This dredge has 3½-cu. ft. close-connected buckets and was designed to dig 20 ft. below the water-level, and is provided with a stacker which was used at the commencement of dredging operations. The dredge is electrically driven and was originally one of the Risdon dredges owned by the Feather River Exploration Co., having 5-ft. open type buckets.

A new ladder and sluice-way of the open structural steel type was built in place of the old ladder. New upper and lower tumblers were used and a line of 3½-ft. close-connected buckets. The revolving screen was lengthened and raised about 6 ft. The extra length of revolving screen was necessary, owing to the fact that the ground contained over 75% of fine material. The extra height was used for the purpose of getting greater area for gold-saving purposes, and also to facilitate resoiling the ground. This extra height of screen necessitated the upper tumbler, gearing, etc., being raised an equal amount and slightly lengthening the ladder and increasing the number of buckets required. It was proposed to put on a secondary screening device, but after some experimental work this was

abandoned and the product from the revolving screen was passed over the gold-saving tables in the usual manner and collected from the tables into three tail sluices, one on each side of the dredge and one in the centre under the stacker ladder and supported by it. The central tail sluice carries nearly twice as much water and fine material as the outside sluices. This central sluice extends about 20 ft. beyond the side sluices.

After operating for some time in this manner the belt was removed from the stacker and a long chute at an angle of about 30° with the horizontal discharged the material from end of the screen above the central sluice-way. All rocks, roots, balls of clay, etc., larger than 4 in. diameter are not allowed to enter the central sluice, and are prevented from doing so by means of a fixed grizzly consisting of bars attached to the lower side of the chute from the screen, and extending out about 3 ft., the outer end of the bars being perfectly free and slightly fan shaped, this prevents the grizzly from getting clogged.

The oversize from the grizzly falls on a V-shaped apron about 3 ft. long, placed on top of the central sluice; the smaller material which passes between the bars falls directly into the central sluice and is carried away by the water and the fine material from the gold saving tables proper. Of course under this

TWO VIEWS OF RESOILED GROUND.

arrangement the sand and small rocks fill the void spaces between the large rocks and thus the swelling of the ground amounts to little, not over 5 per cent in this instance.

As previously stated, there was a large quantity of fine material, but few large rocks and stones. The fine material from the side sluices is not discharged as far from the dredge as that from the central sluice and the coarser material falls on this. It is remarkable how well the ground packs, and the surface is more even after than before dredging was commenced. Of course it is necessary to keep the level of the water in the pond almost at the surface of the ground. There is no more water required for this work than any other dredge of the same capacity, and the cost of operating is considerably less as there is no belt stacker to purchase every ten or twelve months. While it is true that the digging buckets have to lift the material about 6 ft. higher than formerly, there is but a very small increase in power necessary. Not only is the small expense saved in dredging operations, but the principal saving, in my estimation, is in the ground itself. Instead of leaving a pile of unsightly tailing the ground is left as level as a table and in first-class condition for agricultural purposes, inasmuch as the ground has had a deep plowing. The ground in the present case averages from 12 to 15 ft. deep, and was an old orchard before dredging. Trees are now being planted on the new dredged ground. Of course, this method of dredging could not be applied to all dredges now in operation in California. However, there are a number upon which this simple apparatus could be applied, and I believe the results will more than justify the slight additional expense necessary to make the change.

One of the most important iron mines in the world is the Loussavaara-Kiirunavaara, situated at Kiruna, Lapland, in latitude $68\frac{1}{2}^{\circ}$ north, which is about the same as the northernmost boundary of Alaska. The climate is somewhat milder than in Alaska, and these mines are worked the year around. About 1600 men are employed and the equipment is all of the most modern machinery obtainable. Machine tools for the repair shop, air-compressors, and rock-drills, and several of the largest steam and electric shovels are of American make. The plant is operated by steam power, the coal coming from England and Spitzbergen. Steam coal is delivered here for about \$4.50 per ton. The electrification of the mines is in progress, and this power will be used exclusively as soon as the new power-plant of the state of Sweden, now under construction at Porjus falls, is completed. The transmission line is completed and it is expected that the power station will be ready to deliver current early in 1914. The capacity of this station will be 150,000 hp. to be transmitted at 78,000 volts over a distance of 150 miles. The state railway between Kiruna and Narvik is being electrified and will be operated from this station. The ore is shipped from Kiruna to Narvik on the Norwegian coast by rail, and from there by water to Germany, a small percentage finding its way to other countries. The equipment is being rapidly increased and will soon be sufficient to ship more than 10,000,000 tons per

annum. Up to the present time about 25,000,000 tons of ore has been shipped. The ore is magnetite and contains from 53 to $68\frac{1}{2}\%$ iron. Owing to the comparatively large content of phosphorus it was impossible to utilize it until the Thomas furnace was developed.—*Daily Consular Report.*

Annealing of Gold

In a recent paper read by T. K. Rose before the British Iron and Steel Institute, the annealing of gold was discussed as follows. Impurities in gold generally raise the temperature of annealing to a remarkably great extent, different impurities having different effects. The effect of copper is more marked than that of silver, but other elements have far more effect than either. Gold melted on carbon in an atmosphere of hydrogen, although its purity has been reduced only two parts in 100,000, had its temperature of annealing raised from 150 to over 300° . In other cases in which the nature of the impurity was not determined, effects were observed intermediate in magnitude between those due to silver or copper and those caused by hydrogen.

Experiments were made to determine how far annealing could be used as a test for the fineness of gold, supplementary to the ordinary test, by parting assay, and it was clear from the results that, given a particular method of preparation of pure gold, its purity can be easily and quickly tested by annealing it. By the parting assay the composition of fine gold can be determined correctly to 0.01 per 1000 by taking the mean of 20 assays of each sample, weighed to 0.01 per 1000, the amount of metal required for assay being about 10 gm. in each case.

A study of partly annealed specimens of gold shows that recrystallization and softening does not take place simultaneously throughout the mass, but occurs in particular laminae or flattened crystals, while others remain unchanged until more time elapses or the temperature is raised. The new crystals do not increase in size at first, or as a general rule pass the original boundaries of the old distorted crystals, but if heating is continued they soon begin to eat into the original boundaries, which are gradually obliterated. The crystals subsequently increase in size and diminish in number, as is well known. The new crystals appear to be quite soft, and the unaltered laminae as hard as before annealing. The surface indication of softening corresponds to a real comparative softening in depth, and that recrystallization spreads in depth from one lamina to another more readily than sideways, so that superposed laminae are more likely to be similar in hardness than those placed side by side. It followed that partly annealed metal consists of alternate strips of hard and soft material, and consequently that such metal has weak places where its rigidity and resistance to rupture are little higher than those of fully annealed material.

Natural gas consumed in Pennsylvania in 1912 totaled 173,656,003,000 cu. ft., the average price for industrial purposes being 11.53c. per 1000 cubic feet.

The Rand Banket—Part IV

By C. B. HORWOOD

Shape of the 'Pebbles'

As regards the shape of the pyrite replacements, it is remarkable that they are mostly either spheroidal or ellipsoidal and have comparatively smooth rounded contours; except those pseudomorphs formed by the replacement of angular, indurated, slaty-quartzite pebbles, which retain the original outlines. Those that are pseudomorphs after quartz pebbles assume well rounded forms, as they naturally have retained the original shapes of the pebbles replaced. Those again that are pseudomorphs after the ordinary quartzite pebbles are, also, usually spheroidal, as distinguished from those mentioned that have replaced angular slaty-quartzite pebbles. The spheroidal and ellipsoidal shapes of the remainder, that is, of the metasomatic concretions, is undoubtedly due to their mode of origin.¹³⁶ Examination of thin sections under the microscope shows that in the formation of one of these 'pebbles' a minute amount of pyrite was first precipitated; this may have happened either directly from solution in one of the channels or pores through which solutions were passing, or by replacement of silica, or silicates, or by both of these means. Thus a centre of growth was created around which pyrite still continued to be precipitated; and fairly uniform growth at every point would account for the rounded shape. The microscope indicates that there were usually several centres of growth for the same 'pebble.'

Growth of Pebbles

In such cases growth would have ensued independently around each centre; the separate growths having increased in size until they became contiguous, further growth would then have taken place around the now united portions as one mass. After a compact body of pyrite had been formed, its surface would have been exposed to modifying influences due to continually renewed portions of active solution coming in contact with it. Thus any rough outlines due to the consolidation of separate growths, or to the shape of the material last replaced, or to other causes, would gradually have disappeared. If any quartz embayed depressions along the surface it would have been replaced by pyrite, for as already mentioned, the whole process indicates that the already precipitated pyrite acted as a precipitating agent for that still in solution,¹³⁷ and the particular solutions to which we owe this secondary pyrite, had, under the conditions that then obtained, a greater chemical affinity for the silica than for the pyrite; consequently, the former

went into solution while the latter was precipitated. Iddings¹³⁸ has pointed out that in the case of a crystal surrounded by a liquid that can dissolve it, its angles and edges will be dissolved more rapidly than the other portions, resulting in the rounding of its shape. This is owing to the fact that there will be more space around the solid angles and edges for the diffusion of the dissolved material and so the layers here will less readily become saturated, and consequently inactive as a dissolving agent, than the layers of liquid next to other portions of the crystal. Exactly the same reasoning applies in the case under consideration, and explains why any rough outlines would have been obliterated.¹³⁹ Also, according to Riecke,¹⁴⁰ solution is most active at points of greatest pressure. Any roughness of outline would naturally present greater frictional resistance to the flow of solutions and the pressure of the latter would therefore be greatest where this occurred; consequently any unevenness of surface would be toned down. Thus it can be understood why the surfaces of the pyrite 'pebbles' tend to assume that smoothness of outline which is so characteristic of them; and which doubtless caused the earlier observers to regard them as water-worn. Probably, the majority of these replacements are ellipsoidal rather than spheroidal. The writer has observed that those of the former shape have their longer axes parallel to the dip of the strata, demonstrating that in such cases there has been a greater amount of deposition along the directions of the dip and the bedding planes than at right angles to them, clearly indicating that the flow of solutions was along the bedding and parallel to the dip of the conglomerate beds.¹⁴¹

Association of the 'Pebbles' With Rich Ore

Attention has been drawn repeatedly to the asso-

¹³⁶It also explains the frequent rounding of the edges of the pyrite crystals in the banket.

¹⁴⁰'The Nature of Replacement,' by W. Lindgren, *Econ. Geol.* (1912), Vol. VII, No. 6, p. 533.

¹⁴¹Accepting Riecke's theory that solution is most active at points of greatest pressure, then in a pyritic mass in process of formation the surfaces parallel to the bedding-planes would present great frictional resistance to the passage of solutions and would therefore be those where the greatest pressure would exist. Solution along these surfaces would consequently be more rapid than precipitation. On the other hand, the end surfaces at right angles to the bedding-planes and to the direction of the dip would act as barriers and tend to check the rate of flow and so cause precipitation, which would therefore be greater on such surfaces. Hence, the resulting 'pebble' would be ellipsoidal rather than spherical. James Gelkile has already remarked that concretions in laminated clay are usually lenticular, and are often flattened spheroids, owing to the mineral solutions having made their way most readily along the planes of sedimentation. He also explained that continuous seams of limestone or ironstone sometimes occur as a result of the fusing together of continuous nodules of calcareous or ferruginous concretions owing to their tendency to develop in the direction of the bedding-planes of the rock in which they occur. (James Gelkile, *loc. cit.*, pp. 121-122.)

¹³⁸This remark not only applies to the metasomatic concretions which are usually termed pyrite 'pebbles', but also to the small rounded particles and granules of metasomatic origin which occur plentifully scattered through the matrix of the banket.

¹³⁷See also the *Mining and Scientific Press*, *loc. cit.*

¹³⁸'Rock Minerals,' by Joseph P. Iddings, 1st Ed. (1906), p. 74.

ciation of the gold and pyrite in the Rand banket.¹⁴² In the present discussion the invariable association of the pyrite replacements with rich ore has been emphasized; and it has been shown that these metasomatic bodies originated after the deposition of the conglomerate beds. The evidence points to the agency of chemically-active heated solutions (liquid or gaseous) under pressure, ascending from great depth. The lateness of the period in the history of the conglomerate when the pyrite was deposited is proved by films of it occurring along cracks and planes of shearing in both the longitudinal diabase dikes and also in the pebbles of the banket.

Shearing Planes

The planes of shearing go through the pebbles and matrix. Sometimes a pebble is traversed by five or six such cracks, and sometimes each of them has been accompanied by minute step-faulting. These cracks are parallel with the strike of the main structural fractures of the district and with the direction of the big longitudinal, or strike, dikes. Films of pyrite occur here and there both along planes of fracture in the dikes and also on their surfaces; and a thin film of gold can occasionally be found on the dikes, demonstrating that this pyrite and gold has been deposited after the intrusion of these dikes.¹⁴³ In other words, the mineralizers were still circulating after the dikes had been intruded and had developed those various planes of fracture,¹⁴⁴ which are probably mainly due to cooling. The conditions indicate that the solutions, liquid or gaseous, were under great pressure, at high temperatures, and of deep-seated origin; and must, therefore, have been forced, or found their way, along fractures penetrating to great depth. Fractures of such extent and persistence must have been the main structural ones of the district. Their places are now marked by decomposed diabase

dikes (offshoots intruded into them from the underlying magma) which finally sealed them against the passage of further mineralizers and of the silicious solutions such as had already to a great extent, by the deposition of secondary silica, closed the pores of the now auriferous bankets and prevented their further permeation by the deep-seated agents to which they owe their pyrite and gold. Thus the mineralization and dike intrusions became possible by extensive fracturing of the strata by means of which communication was established with the underlying molten magma. After the dikes had cooled and contracted, solutions still for a time found their way along them and through their fractures, and continued to deposit their mineral contents until in most cases they eventually closed even these channels by the deposition of silica or other mineral matter. The close and intimate intergrowth of the gold and pyrite and the fact that the former is so frequently bound up mechanically in the latter,¹⁴⁵ and the further fact that the pyrite replacements are a sure indication of gold are sufficient evidence that they were deposited more or less simultaneously from the same solutions; and rather suggests that the two may have been present as a eutectic mixture. If so, the pyrite present in excess of the eutectic ratio would first have been precipitated until the eutectic point was reached, when the gold and pyrite would then have both come down together as a eutectic mixture. George Barrow,¹⁴⁶ of the Geological Survey of Great Britain, has suggested the possibility of a gaseous eutectic mixture. There are molten eutectic mixtures, therefore why not gaseous ones? If there be, there is no difficulty in imagining a sufficiently high temperature to render gaseous the minerals found in veins such as pyrite, or a metallic element such as gold.

Influence of Slates and Shales on the Mineral Deposition¹⁴⁷

The descriptions of the occurrences of pyrite 'peb-

¹⁴³Similar reasoning has been applied to show that the flints in the English chalk are not only later than the latter, but later even than the period during which it was elevated and became dry land, because flints are found occupying vertical joints and cracks in the chalk and these cracks are certainly of later origin than the deposition of the chalk, there is indeed little doubt that they were produced as a consequence of its gradual upheaval. (W. J. Sollas, *loc. cit.*, pp. 152-154.)

¹⁴⁴The main fractures are usually roughly parallel to the walls of the dikes. The dikes here referred to are the longitudinal, or strike, dikes. They are all diabase dikes, highly decomposed and urallitized.

¹⁴⁵L. De Launay pointed out that the gold in the Rand banket is constantly associated with pyrite, but does not seem to be combined with it, and that the gold can often be seen, under the microscope, in crystals enclosed within the pyrite. *Loc. cit.* (1903), p. 519.

T. A. Rickard has shown that, as regards the occurrence of gold in the pyritic quartz of lodes, the evidence indicates that the gold does not exist in chemical combination, but as minute filaments or crystal aggregates distributed through the substance, especially along the structural planes of the pyrite. Further, that when the gold-bearing pyrite is treated by cyaniding, the gold may be leached out without deformation of the pyrite or any other change in its appearance except the acquisition by its facets of a pitted surface suggesting cavities left by the removal of a soluble constituent. ('The Formation of Bonanzas in Gold-Veins,' in 'The Genesis of Ore Deposits,' 2nd Ed., pp. 738 and 739.)

That the gold which is present in the pyrite of the Rand banket is mainly, and probably entirely, bound up in it mechanically is demonstrated from it being easily detected and separated (or most of it) from the pyrite in panning; from microscopical studies; from its largely yielding to amalgamation; and from the battery pulp readily giving up its gold in the cyanide process.

¹⁴⁶*Trans. Inst. Min. and Met.*, Vol. XVIII (1909), pp. 231-234.

¹⁴⁷The discussion under this heading is a good example

bles' at the Crown Reef, Rietfontein, and Randfontein mines clearly showed that they were closely related to dike intrusion and rich ore; and to the retaining influence, in the case of the first, of a thin underlying impervious band of shale; and, at Rietfontein, of a shaly talcose foot-wall. At Randfontein the foot-wall of the Leader is usually sericitic and shaly, and has doubtless exerted a similar influence. Van Hise¹⁴⁸ has strongly emphasized the profound influence of impervious strata upon the deposition of ore. The foregoing merely illustrate local examples of the effect of thin bands of shale; or, even of sericitization along a foot-wall. The retaining influence of shale¹⁴⁹ has, however, a wide and important bearing throughout the whole of the Rand goldfield, which extends for more than 60 miles along the strike of the conglomerate beds. As long ago as 1905, the writer pointed out that, if the theory that the gold originated from ascending mineralizing solutions be accepted,¹⁵⁰ it is easy to understand how solutions may have come up along lines of weakness such as the junction-planes between dikes and their walls, and that during their ascent a point would be reached where it would be easier for them to spread out laterally along the bedding than to ascend farther in a more vertical direction. Further, that as this position would be determined by the porosity of the beds, depending largely on the compression caused by the superincumbent weight of strata,¹⁵¹ the solutions would naturally select a conglomerate bed. The first of these, with the exception of a few in the Lower Witwatersrand formation, including perhaps the Du Preez series, would be the Main Reef series; and, the impervious foot-wall slate, which lies at their base, would doubtless have exerted a favorable influence by helping to retain the mineralizing solutions above it. He also, at the same time, stated that the underlying conglomerates, which do not contain sufficient gold to be exploited, did not afford such easy channels, being composed of smaller pebbles, and being more compact owing to a greater weight of overlying strata; further, that traces of gold could be

of the important bearing that questions of economic geology often have on actual mining practice; and, incidentally, shows how knowledge obtained from scientific investigation of the origin and concentration of the gold in the banket can prevent money being squandered in useless prospecting work on conglomerates unlikely to contain enough gold to be exploited profitably.

¹⁴⁸'Some Principles Controlling the Deposition of Ores,' in 'The Genesis of Ore Deposits,' 2nd Ed. (1902), pp. 396-416 and 780. See also, in the same volume, 'The Role of the Igneous Rocks in the Formation of Veins,' by J. F. Kemp, p. 699.

¹⁴⁹The terms 'shales' and 'slates' have in the past been rather loosely used to describe various members of the Witwatersrand system. The beds, to which one or other of these terms is applied, are generally fine-grained argillaceous quartzites in which slaty cleavage is often, but not invariably, developed.

¹⁵⁰The reader will find a bibliography of the literature on this subject in the *Proc. Geol. Soc. So. Af.* (to accompany Vol. VIII of the *Trans.*, 1905), p. 28. For later writings on the subject, see the various references in the present paper.

¹⁵¹Consisting of slates, quartzites, and conglomerates, each of which would, under similar conditions, be more porous than the one before named.

found in every series and in much of the intervening quartzites, showing that the whole of the Witwatersrand beds had been, to some extent, permeated by mineralizing solutions; but, that the main circulation was doubtless confined to certain channels such as those suggested.¹⁵² George G. Holmes,¹⁵³ manager of the New Goch mine, speaking in a general way to the writer in the early part of 1912, also expressed the opinion that the good average grade of the Main and South Reef sub-series of conglomerates throughout the Rand was due to the retaining influence of the big mass of slates several hundred feet thick under the former, or lower, of these two sub-series. It has been seen that the writer entirely agrees with this opinion. The conglomerates below these broad belts of slate are at a much lower geological horizon and are, therefore, as just stated, more compact; they are also smaller and less defined; and, thus formed less suitable courses for the ascending solutions.

Mineral-Bearing Solutions

On the other hand, above the Main Reef foot-wall slates, the mineralizers were in a higher geological horizon, where the strata were less compact, and they encountered a series of coarse conglomerates along which they could easily flow. In addition to their lateral motion they would also have had a downward component due to gravity, which would be checked as the neighborhood of the foot-wall slates was reached; thus the greater proportion of their gold contents would have been precipitated in that series of conglomerates nearest the basal slates; in this latter series along the central portion of the Rand, the thin Main Reef Leader is immediately underlain by a thin impervious band of shale, only a few inches thick, by which it is separated from the poor underlying Main Reef.¹⁵⁴ The good average grade of the Main Reef Leader, especially along the Central Rand, compared to the much more erratic yield of the South Reef Leader, is doubtless due to the retaining influence of this thin shale band. Beyond this area, where the thin shale band underlying the Main Reef Leader is sometimes missing, and the Main Reef Leader also is sometimes either missing or poorly developed, the Main Reef itself¹⁵⁵ often rests immediately on a talcose foot-wall, or on the underlying foot-wall slate. This is so on the Far East Rand, where the Main Reef is locally known as the Van Ryn Reef, and in such cases it is the gold-carrier or 'pay-reef' of the district. The fact that the average grade of the Main Reef series is more uniform than that of the South Reef series is doubtless due to it being nearer than the latter to

¹⁵²'The Witwatersrand and Associated Beds,' by C. B. Horwood (June 1905), Esson and Perkins, Johannesburg, pp. 61-62.

¹⁵³G. G. Holmes has enriched our geological knowledge of South Africa by much valuable field-work in various parts. He is not merely a deep thinker, but is also an accurate observer.

¹⁵⁴The description already given of the section of the Main Reef sub-series at the Crown Reef mine may be taken as typical.

¹⁵⁵Under these conditions the Main Reef series is sometimes represented by a single bed of conglomerate, or is accompanied merely by one or more insignificant, overlying, leaders.

the foot-wall slates below the Main Reef. It is certainly a remarkable fact, otherwise difficult to explain, that, speaking generally for the whole Rand, the yield of the South Reef Leader, which is not immediately underlain by shale, is far less reliable than that of the Main Reef Leader, which usually lies some 60 to 120 ft. or more below it. In the absence of modifying conditions such as the presence of a shaly, talcose, or sericitic foot-wall, the tendency can frequently be observed for the gold to be spread over several bands of conglomerate (which are often thin and separated by barren quartzite) in such a way that the total gold contents cannot be mined within a sufficiently narrow stope-width to extract it profitably. On the other hand, when one of the ancient channels of circulation has been

outcrops,¹⁵⁷ probably nearly twice the amount of the yield to date,¹⁵⁸ would not in the future be available.

Iridosmine in the Banket

The writer has dealt elsewhere with this subject¹⁵⁹ and mentioned several mines where iridosmine has been noticed in minute quantities associated with the gold, for example, at the Modderfontein, East Rand Proprietary, Randfontein, and Rietfontein mines; also from the banket in the Black Reef formation at Klerksdorp and in the banket that immediately underlies the diabase at the Steyn's Es-

¹⁵⁷This depth will certainly not mark the limit to which profitable mining will be extended.

F. H. Hatch has shown that figuring on the data obtained from H. F. Marriott's experiments, which demonstrate that

FIG. 21. LIGHT-GRAY QUARTZITE WITH LINES OF VISIBLE GOLD, INDICATED, AS TO POSITION AND THICKNESS, BY THE BLACK MARKINGS. SOUTH RANDFONTEIN. NATURAL SIZE.

restricted owing, say, to a reduction in the thickness of the banket, or, for a short distance, to entire absence of pebbles, the gold is frequently concentrated in this narrowed area; and, in the latter case often into a line of visible gold along the contact of both walls, as illustrated in Fig. 21.

Influence of Slate and Shale

The result of the retaining influence of slate and shale is thus of great economic importance. It is not merely that the more uniform yield of gold from the Main Reef sub-series, as compared with that from the South Reef sub-series, has affected actual mining operations, but that except for the retaining influence of slates and shales it might have been that the gold of the Rand was not sufficiently concentrated in any particular series of conglomerates to pay for extraction; in which case the £347,000,000 worth of gold already won,¹⁵⁶ would have remained in the ground; and the gold still obtainable down to a vertical depth of, say, 5500 ft. below the banket

on the Rand the rise of temperature with depth is only 1°F. for every 208 ft. of depth, the temperature at 7000 ft. would be about 97.5°F. He also pointed out that the electrical transmission of power as applied to stage-winding has so modified mining engineers' ideas of the depth at which mining is practicable, that it is now generally assumed that no mechanical difficulties exist which cannot be overcome, if it pays to do so. 'The Past, Present, and Future of the Gold-Mining Industry of the Witwatersand, Transvaal,' by F. H. Hatch. *Min. Proc. Inst. C. E.*, Vol. 186 (1911).

¹⁵⁸This means a total of, say, £1,000,000,000 down to a vertical depth of 5500 feet.

T. H. Leggett and F. H. Hatch, in 1902, estimated the total gold production from the Main Reef series down to a vertical depth of 6000 ft. at £1,310,300,000. The average figure used by them for gold recovery, was 38s. per ton milled. At the time the average recovery was 42s. 'An Estimate of the Gold Production and Life of the Main Reef Series, Witwatersrand, down to 6000 ft.,' by T. H. Leggett and F. H. Hatch. *Trans. Inst. Min. and Met.*, Vol. XII (1902-3), p. 39. The recovery has since gradually decreased; and, for the year 1912 was only 29s.

It was hardly anticipated ten years ago that low-grade rock (of, say, an assay value of about 5 dwt.), from the deep-level ground of the Rand, would ever be of economic value. Now large tonnages of low-grade ore can be, and are, included in the ore reserves and can be profitably treated; thus greatly adding to the life of the Rand as a gold-producer.

¹⁵⁹C. B. Horwood (1912), *op. cit.*

¹⁵⁶This is from and including the year 1887 up to the end of December 1912. The actual figures, as closely as they can be estimated, are: 81,703,602 oz. of fine gold, valued at £347,054,851. Out of this, £91,502,871 has been paid in dividends. (*So. Af. Min. Jour.*, Jan. 18, 1913.)

particular analyses of the iridosmine concentrate disclosed the presence of osmium, ruthenium, and iridium, constituting apparently the bulk of the material. Iron, chromium, calcium, aluminum, titanium, magnesium, strontium, sodium, manganese, and silicon lines were also present.¹⁶² A chemical analysis,¹⁶³ made by the Imperial Institute authorities,¹⁶⁴ was also given at the same time. The concentrate had a specific gravity of about 19 and was found to have the following composition:

	Per cent.
Gold	1.24
Platinum	0.61
Iron (expressed as Fe_2O_3)	1.29
Nickel (expressed as NiO)	0.66
Osmiridium (Ir, Os, and allied metals)	95.52
	99.32

The osmiridium was found to contain about 45% of iridium; but Mr. Dunstan pointed out that the result of a single analysis may be misleading, as osmiridium varies greatly in composition even in the case of samples from the same locality.

Genesis of Osmiridium

In discussing the genesis of this substance, the present writer emphasized the fact that the atomic weights of gold, iridium, osmium, and ruthenium are 197, 193, 191, and 102, respectively, and that the elements of highest atomic weight are, on the whole, relatively the rarest in rocks; further, that if one could explain why elements of high atomic weights are rare, then, as R. K. Duncan has pointed out, the explanation of the genesis of matter would probably be revealed.¹⁶⁵ The forty years' labor of Sir Norman Lockyer¹⁶⁶ has accustomed the world to the conception of an inorganic evolution in the sun and stars according to their supposed differences of temperature; and he ranged certain elements in the order of their appearance in these stars. The radio-active elements, on the other hand, such as radium, thorium, uranium, etc., possess the heaviest atoms known, and their radio-activity seems to depend upon their devolution into simpler elements. It may thus be that the lighter elements are taking up as much energy when evolving into heavier elements as is given out by the latter in disintegrating into the former.¹⁶⁷ As regards the genesis of the iridosmine

in the Rietfontein mines, he pointed out that it was associated with gold and pyrite and seemed mostly to occur in that seam known as the Carbon Leader;¹⁶⁸ some of it was distinctly crystalline; it was accompanied by a small proportion of nickel and a little chromium, both of which occur in basic rocks as a product of differentiation of an igneous magma; moreover, the original home of the platinum metals, often with some gold and chromite, is the basic and ultra-basic rocks, in which they exist as primary segregations formed by magmatic concentration; further, that the metallic elements of the auriferous bankets, gold, silver, iron, cobalt, copper,¹⁶⁹ and nickel, together with the metals of the platinum group, form three analogous series, all occurring in Group VIII of Mendeléeff's table,¹⁷⁰ and that this association, agreeing as it does in such a striking way with their chemical association and their grouping by Mendeléeff according to their atomic weights, valencies, and other chemical properties, is too remarkable to be purely accidental and must surely indicate a close genetic relationship; therefore, if a particular genesis be admitted for any one of them it must seemingly be admitted for them all. He laid stress also on the fact that the iridosmine was associated with gold, silver, pyrite, carbon, and traces of cobalt, all of which had already been shown to occur in neighboring basic dikes encountered in the mines of the Rand and, that in these Rietfontein mines basic rocks are abundantly represented by big persistent diabase dikes, 80 to 120 ft. thick, which are exposed underground for a distance of nearly two miles. He maintained that the auriferous Rand

¹⁶⁸Reference has previously been made to this 'reef' in this paper.

¹⁶⁹It is interesting to note that traces of copper occur in the Klipriversberg diabase (Horwood (1910), *op. cit.*, p. 38), with which the longitudinal dikes, in the mines of the Rand, are doubtless genetically connected.

¹⁷⁰The reader is referred to the table of the elements as revised by this famous Russian chemist as recently as 1904 to include all the known elements except the 'rare earths.' It is true that copper, silver, and gold are usually considered as occurring in series 5, 7, and 11, respectively, under group I. It will, however, be seen that Mendeléeff indicates their very close relationship to the three analogous series of group VIII by also including them, in brackets, under that group. In the first analogous series of this group are iron, cobalt, nickel, and copper. Iron is largely present in the Rand bankets, chiefly in the form of iron pyrite, which, as previously stated, occurs in quantities varying from about 2 to 3%. Cobalt, nickel, and copper occur in minute quantities throughout the mines of the Rand (they can be detected by analysis in the cyanide solutions: see Horwood (1910), *op. cit.*, p. 72). Ruthenium, rhodium, palladium, and silver form the second analogous series. Both spectroscopic analyses showed that ruthenium was largely present in the heavy concentrate from Rietfontein. The probable presence of rhodium and palladium was established by the first spectroscopic analysis. Silver occurs associated with the gold of the Rand to the extent of about 125 parts per thousand of bullion. The third analogous series of this group consists of osmium, iridium, platinum, and gold. The chemical analysis and both spectroscopic analyses showed that the Rietfontein concentrate was largely composed of these first two elements. The chemical analysis disclosed the presence of platinum; and the spectroscopic investigation of the first sample had also suggested its presence. In Rand bullion, gold accounts for about 875 parts per thousand: see Horwood (1910), *op. cit.*, pp. 72, 77, and 82; also Horwood (1912); *op. cit.*

¹⁶²There were traces of the strongest lines of vanadium; and indications that rhodium, platinum, and palladium were also present. Many other rare elements, including radium, were sought, but were not found.

¹⁶³The sample used was a portion of one from the Rietfontein mines; the other portion had already been used for the second spectroscopic analysis (the upper one in Fig. 22).

¹⁶⁴Through the courtesy of the Transvaal Mines Department and R. N. Kotzé, the Government Mining Engineer, who obliged the writer by making an official request for a quantitative analysis of this concentrate; and the director (Wyndham R. Dunstan, F.R.S.) kindly had this done.

Tilden (1910), chapter 4 (Harper Bros.).

bankets differ in no important essentials from ordinary gold-bearing quartz-veins; and that dikes are sufficient evidence of former deep-seated communications; he remarked that Kemp¹⁷¹ laid special stress on the almost constant association of eruptive rocks with veins and the usually very restricted occurrence of the latter and rightly argued that considered as to area there is adequate reason to attribute to these rocks a great importance in vein production. Therefore the writer concluded that these metals are of secondary origin, and had existed in minute proportion as primary segregations, formed by magmatic concentration, in the basic eruptives of these mines, from which they were extracted by active superheated gases; still later hydrothermal action probably playing an important part in concentrating them in the bankets.

Crystalline Structure

R. B. Young,¹⁷² in combating these conclusions, says that the present writer stated that "the iridosmine shows no signs of being water-worn" and that "it consists of crystals with perfectly sharp edges and smooth faces." What the latter actually stated was that "the iridosmine, and the gold with which it is associated, is crystalline; and does not show evidence of being water-worn, as one would expect it to do, if it were an original constituent of the banket."¹⁷³ At the meeting of the Geological Society of South Africa, subsequent to the one when his paper on the iridosmine was read (in reply to a query from Professor Young), he said that the Rietfontein concentrate contained sharp angular particles of iridosmine: which it does. He did not say that the concentrate consisted entirely of angular grains and contained no rounded ones. In fact, when examined under the microscope, the roundness of grain as compared with iridosmine concentrates from other sources is seen to be one of the chief characteristics of the iridosmine from the Transvaal bankets. Young refrained from discussing the paper at that meeting while the writer, who was just leaving Johannesburg for England, was there to reply. Consequently, the writer did not disclose all his evidence, or the main features of his slides; but, at Young's request, he agreed on his return to England to find his slides¹⁷⁴ and send them for Young to see. Pressure of business in England and then a visit to Germany prevented him doing this immediately. In the meantime, without waiting for the slides, Young¹⁷⁵ attacked his conclusions in a brief paper, basing his opinion that the iridosmine is of detrital origin on the rounded form of the mineral grains and their association with what he considered detrital chromite; and on

the fact that it occurs in conglomerates where a concentration of heavy minerals might have taken place during sedimentation. The last argument can equally well be used to argue that the gold is of placer origin, and Young admits it is not. As regards his other two arguments, the present writer had already pointed out that the concentrate was associated with nickel and chromium, but had referred their origin to the dikes. He had shown that traces of nickel occur associated with the gold of the Rand and can be detected in analyzing the cyanide solutions;¹⁷⁶ and later in the present paper he instances the occurrence of nickel in a basic dike at Pilgrim's Rest;¹⁷⁷ and also shows that chromium is one of the agents responsible for the pigment of the black-edged pebbles in the banket; and further that it was probably introduced into them under pneumatolytic conditions.¹⁷⁸ Young in calling the chromite detrital is merely expressing an opinion. Young states¹⁷⁹ that in the samples from Rietfontein and Klerksdorp that he has examined "distinct crystals are moderately common, but in every instance the edges are rounded off. Every gradation can be observed from crystals in which the faces are plainly discernible to rounded grains in which one can just trace the original hexagonal form. A large proportion of the iridosmine is in beautifully rounded grains, bearing no trace of crystalline form. Cleavage flakes and irregular fragments also occur." He then illustrates the general rounding of the grains by means of two photographs.

Rounded Forms of Iridosmine

As regards the rounded form of the iridosmine grains being proof of detrital origin, the early observers fell into similar error over the so-called 'rolled' pyrite 'pebbles.' The iridosmine of admitted detrital origin from the Urals, California, Brazil, New South Wales, and Tasmania has a flaky habit and the extent to which it has been abraded is slight. The iridosmine from the auriferous banket from the Rietfontein mines and from Klerksdorp differs from the former in two striking respects, namely, in the minuteness of the grains, and in their extremely rounded form. Prof. Young in his argument points to occasional crystals of other minerals, showing no trace of rounding, and says the hard iridosmine crystals without exception have rounded edges; and concludes that these features dispose of any contention that the rounding was produced during the various processes to which the ore was subjected before the iridosmine was finally extracted from the ore. In the iridosmine of known detrital origin and in that from the South African bankets sharp angular fragments occur; but since the grains are so much smaller and are mostly of such extremely rounded form in the latter as compared with the former, if the rounding was due to abrasion one would hardly expect that angularity of any of the particles could have survived in these South African concentrates. Owing to high surface-

¹⁷⁹Young (1913), *op. cit.*, pp. 113-114.

tension, metallic particles when heated to temperatures above their melting points usually assume a more or less spherical form. Thus it is well known that when small irregular particles of copper are allowed to fall through a tube heated well above 2000°C. they become approximately spherical. In making lead shot, the molten metal when poured on a sieve and allowed to fall a considerable distance is disintegrated and the particles become spherical. If small irregular pieces of silver, gold, platinum, or other metals of the platinum group are heated to above their melting points on cupels they assume spherical shapes. When platinum wire is heated before a strong oxy-coal-gas blowpipe flame, the platinum melts and falls down in small rounded globules.

Extraction of Iridosmine from Dikes

The writer concluded that pneumatolysis had been responsible for the extraction of the iridosmine from the dikes; which would involve a higher temperature than that required for the molten metal: thus similar laws would apply, and the tendency on cooling would be to assume spherical forms,¹⁸⁰ and this explanation would account for the roundness of grain. In making room for itself, metasomatism may also have come into play; as in the case of the pyrite and of the carbon. The fact that rounded particles, sharp and irregular grains, and crystals occur together in the iridosmine concentrate strengthens the similarity of its occurrence to that of the pyrite in the Rand banket; and it is now generally admitted, as in the previous pages it has been shown, that the latter is not of detrital origin. Apart from roundness of form due to influences operating at the time of the deposition, the writer has also accounted for possible subsequent rounding of angles and edges of crystals when discussing the shape of the pyrite 'pebbles.' Similar reasoning applies in this case; the prevailing roundness of the grains is therefore no evidence that the iridosmine is water-worn. On the other hand, its crystalline character is undisputed. On a previous occasion Young¹⁸¹ had given a description of it, as obtained after the gold ore had been treated in the stamp-batteries, in the following words: "It is got in flattened and rounded grains, and in tubular six-sided and rhombohedral crystals, both averaging in diameter about 0.12 mm. In the crystals the basal and rhombohedral faces are distinct, the prism faces less so or absent. The basal cleavage is distinct, many of the grains being in the form of basal flakes, probably produced, in part at least, during the crushing of the rock." In basing his conclusion that the iridosmine is of detrital origin on the general roundness of its grains, he had apparently forgotten that in discussing the occurrence of pyrite 'nodules' or 'pebbles' in the banket he contended that the shape was the "direct result of the mode and conditions of their growth,"¹⁸² and also that he had stated he was of opinion that "the rounded form of a pyrite grain affords no reliable

evidence of its detrital origin."¹⁸³ The present writer contends that the same remarks apply equally well to the iridosmine of the bankets.

Deposition of Carbon

The carbon, which is certainly not of detrital origin, exists in warty, rounded, grains, and, as we have seen, investigations indicate that it was deposited at high temperature from a gaseous state, or from a very mobile liquid. The writer's researches on the origin of the iridosmine indicated the basic dikes as their source. Recently Alfred Fowler¹⁸⁴ has kindly undertaken a spectroscopic investigation of specimens of the big diabase dike in the Rietfontein mines to ascertain whether it would reveal traces of iridium and osmium. At first he thought some lines were faintly shown, but further work did not confirm this. As already stated, the amount of iridosmine present in the banket is so minute that it has never been discovered in place. At the Rietfontein mines it took about six months to collect some 910 grains of the concentrate, during which time 102,800 tons of ore was crushed, and over 52,500 ounces of fine gold was recovered.¹⁸⁵ Thus if its presence in the banket be due to the intrusion of these dikes it is only to be expected that any still remaining in them would exist in such minute proportion as not even to be capable of detection by so delicate a method as spectroscopic analysis. The final spectroscopic results were based upon photographs taken with a 10-ft. concave grating. The presence of iridium, osmium, ruthenium, platinum, or nickel was not detected, although long exposures were given in order to register the fainter lines of the spectrum. Among the elements present in the samples were aluminum, magnesium, chromium, titanium, scandium, and vanadium. The spectroscopic examinations of iridosmine concentrate from Rietfontein had revealed the presence of these first four elements; and the slightest trace of the strongest vanadium lines had also been obtained. Thus five out of six of these elements had been found in the concentrate. One of the characteristic minerals, associated with the Rietfontein

¹⁸³Young (1907), *loc. cit.*, p. 20. In describing the occurrence of pyrite in the banket, he says it is of especial interest as it is generally the gold-bearer of the rocks; that in a number of the microscopic sections which he has examined almost every pyrite grain is beautifully crystallized and shows no trace of rounding; but that it is a fact that a large proportion of the pyrite in the banket occurs in the form of rounded grains, and he mentions that Becker gave their average diameter as 0.1 mm. and that the latter stated that they constitute most of the pyrite in the banket. Young then states that as a result of his own investigations he is "of opinion that the rounded form of a pyrite grain affords no reliable evidence of its detrital origin."

¹⁸⁴Mr. Fowler, who is a Fellow of the Royal Society and one of the greatest living authorities on spectroscopic work, was for many years closely associated with Sir J. Norman Lockyer in his world-famed work.

¹⁸⁵These figures indicate that the Rietfontein lodes contain about 27,500 times as much gold as metals of the platinum group. However, it must be remembered that the gold recovered was obtained both from the mill and the cyanide plant; but the iridosmine concentrate was obtained only from the battery, and it is just possible that a little may have passed to the cyanide works and been lost.

¹⁸⁰As cosmic bodies do on gradual cooling from a gaseous state.

¹⁸²Young (1909), *op. cit.*, p. 88.

iridosmine, and the one on which Young lays so much stress, is chromite. The spectroscopic examination of samples¹⁸⁶ of the neighboring basic dike has thus revealed a definite source of chromium. Young argued that the source of the iridosmine must be the same as that of the chromium; he assumed that the latter was of detrital origin and suggested the ultra-basic rocks of the Swaziland system as its source; whereas Mr. Fowler's research work has demonstrated that there is no occasion for such assumptions as a source exists in the basic rocks occurring in the mines, in the immediate prox-

¹⁸⁶The samples consisted of portions of bore-hole cores from the central portion of the main dike.

imity of the bankets containing the chromium and iridosmine. The foregoing facts and arguments and the association of the iridosmine with gold, silver, pyrite, carbon, traces of cobalt, and also with chromium, all of which have been shown to occur in the neighboring dikes, indicate the latter as the responsible agents for the minute quantities of these rare metals in the auriferous banket.¹⁸⁷

¹⁸⁷It is quite possible that there may be a small proportion of pyrite and gold of detrital origin in the banket; but, if so, it is admittedly unimportant in discussing the genesis of the pyrite and gold; and the same remarks apply with regard to these rare metals.

(To Be Continued.)

Valdez Creek Placer Mines

By GEORGE W. SIAS

During the season of 1913 the Valdez Creek Placer Mines completed a large ditch $1\frac{1}{4}$ miles in length having a capacity of 2500 miner's inches with a grade of $\frac{1}{2}$ in. to the rod, laid 2800 ft. of pipe, built a penstock, a by-wash ditch with a length of nearly one mile, put in a flume, and started hydraulicking operations on August 1 on the famous claim known as the 'Tammany' on Valdez creek. On this claim in the year 1907 an adit was started on bedrock, and from 1907 to 1911 this work had been extended by lateral drifts and stopes to an average of 25 ft. wide, 7 ft. high, and 1200 ft. long. On the bedrock of this old channel some of these drifts had been run out on each side at least 100 ft., showing that the bedrock was in places 200 ft. wide between the rims.

Grade of Gravel Being Handled

In doing this work and proving up the value of the gravel on the bedrock, more than \$160,000 was taken out. In the report made on this property by Forbes Rickard in 1911, he estimated the entire bank would run 94c. per cubic yard. This year hydraulic operations on the face of this bank, cutting the bank back 125 ft., proved in the clean-up that the gravels averaged \$1.50 per cubic yard in that part of the bank above the old workings. Every hour of piping into the flume averaged about \$100, and the values found more than confirm the estimate of Mr. Rickard and prove beyond question the old channel. Furthermore, the work done on this bank of gravel shows the face 110 ft. high and 200 ft. wide. These are the claims that Mr. Rickard had estimated could be worked for twenty years. It is easy to estimate from the results of this season's work the wealth of gold that will be taken out when this channel has been hydraulicked back for one mile, and all the geologists who have visited the creek believe that it extends many miles.

The trustees of the Company are contemplating sending in 6000 ft. of pipe of 36-in. intake, with necessary equipment, and having it ready for work, under a head of 300 ft., not later than July 1, 1914. This would give an additional capacity of not less than 5000 yd. per 24 hours for 150 working days.

The trustees are more than satisfied with results for the year 1913, as there had been some speculation as to what this large bank of gravel would run.

In doing assessment work on other claims, gravel of value was found, especially on Lucky Gulch, a property seven miles above, which the geologists, including those representing the U. S. Geological Survey, considered to be the source of the gold in the old Tammany channel mentioned above. Here the men have recovered by hand work in a short time this season about \$3000 in dust, including nuggets ranging from \$5 to \$60. Indeed, many nuggets of from \$5 to over \$900 are often found in the sluice-boxes on these claims.

There is a large acreage on this property, and with a proper equipment installed, the management believes that the amount of gold recovered from this property will be surprisingly large. On Discovery, about one mile below the Monahan adit, in doing the assessment work, coarse gold was shoveled into the boxes, which proves that there is a large amount of gold to be recovered from the benches below, as the engineers have asserted would be the case. The trustees have underwritten the bonds and it is their intention to send in a No. 4 Keystone drill and an Empire drill with pipe and other supplies for the year 1914 at an early date.

Australian Copper Production

September returns from some of the principal mines were as follows:

Mine.	Ore treated, Copper,		Gold,	Silver,
	tons.	tons.	oz.	oz.
Great Cobar	532	2411	10,819
Great Fitzroy	9,121	184	961	2,371
Hampden Cloncurry ...	5,160	509	141	4,336
Mt. Elliott	4,212	500	820	1,160
Mt. Lyell	28,721	589	742	41,343
Mt. Morgan	22,667	694	8827

¹⁸⁸Dredges operating in the South Island of New Zealand during 1912 numbered 87, and produced gold worth \$1,230,000, of which \$187,000 was paid in dividends by registered companies.

Big Business and Industrial Prosperity

By C. R. VAN HISE

*There can be no question that the competitive system, when unrestrained, is positively opposed to the policy of conservation. This is true alike for minerals and timber. The minerals of the earth require the building of the earth for their making. Mineral deposits are doubtless in the process of manufacture at the present time; but even if so, this is at so low a rate as to be negligible. From the point of view of mankind, the stores of minerals in the earth are deposits of definite magnitude upon which we may draw but once and which by no possibility can be increased. In this connection it should be recognized that modern civilization would not be possible without the mineral resources of the earth—no iron ships, no tools except those of stone, no fuel but wood. Without the sub-surface products of the earth we would at once return to the material conditions of the stone age. It is therefore incontrovertible that from the point of view of the human race, economic systems or laws which result in unnecessarily rapid use of the mineral stores of the earth are indefensible; but such are the economic theories and laws now dominant in the United States.

Wastefulness of the Competitive System

The wastefulness of the competitive system may be proved with regard to every product which is taken from the earth. Lead and zinc in Wisconsin and Missouri are mined on a small scale under an extreme competitive system. The losses of these metals in their mining and metallurgy are nothing short of appalling. In Missouri, according to the late E. R. Buckley, not less than 15% of the metal is left underground; the losses in concentration approach 15%; the loss in smelting and concentration frequently amount to 15 or 20%; thus making a total loss of from 45 to 50%. These great losses are due to the system of numerous small holdings combined with the competitive system. High royalties on the part of the small feeholder are demanded of the operator. The operators desire to get large returns at the earliest practical moment upon this small investment. In consequence, ore is left in the ground that should be mined; unnecessary losses take place in concentration; also unnecessary losses occur in smelting.

But the most disastrous losses in mining as far as the future of the human race is concerned are in connection with coal. J. A. Holmes, of the United States Bureau of Mines, in a paper upon mineral wastes, presents the facts in regard to the ruinous wastes of the unrestrained competitive system in connection with coal. He says that in the early days of mining when there was much subdivision of ownership, not more than 30 to 40% of the anthracite coal in the veins mined was brought to the surface, leaving 60 to 70% in the ground. He states that even at the present time not more than 50% of

the anthracite reaches the surface. The situation is similar for bituminous coal, but until recently the losses for such coal was substantially half. This loss has been somewhat reduced, but it continues to be appalling. Holmes estimates that since the beginning of mining in the United States, two billion tons of anthracite and three billion tons of bituminous coal have been left underground in such condition as to make their future recovery doubtful or impossible. The principles which from the point of view of conservation should apply to the mining of coal are well known. So far as practicable the mines should be so worked as to make one superimposed vein after the other available. Coal slack should be reduced in amount and utilized. No considerable percentage of coal should be left in the ground as pillars. If these reforms were introduced, the losses could be reduced to half the present amounts and possibly to one-fourth.

But to ask that any such proposals should be put into operation is purely chimerical. Under the Sherman law there is no opportunity to limit output, divide territory, or regulate prices. Five thousand bituminous operators could produce two hundred millions of tons of coal per annum beyond present demands. If the operators could agree upon limitation of output, and division of market so as to reduce freights, and could arrange for reasonable prices, which would give them no more than their present profits, they would then be able to follow these principles in mining their coal; for they themselves would be gainers in prolonging the life of their mines, and far more important many future generations would be the immeasurable gainers in that they would have an adequate coal supply. Under the competitive system, we are recklessly skimming the cream of the natural resources of a virgin continent with no regard for the rights of our children or our children's children. They will have a heavy score against us if we continue to ignore the future and to apply the unrestrained competitive system in total disregard of their rights.

Remedy for Existing Conditions

My proposal to remedy these conditions is neither regulated competition, nor regulated monopoly, but retention of competition, prohibition of monopoly, permission for coöperation, and regulation of the latter. At the present time there are state and national movements to still further extend the advantages of coöperation to the farmers. Since it is unquestionable that the sense of justice of the citizens of the United States will support the courts in prohibiting class legislation, we shall, therefore, I believe, ultimately permit coöperation in all lines of business alike. If we, however, retain freedom of competition, permit concentration sufficient to give efficiency, allow reasonable coöperation, and prevent monopoly, this will require regulation just as it has been necessary to regulate the railroads. This done, the Sherman law will be forgotten. Has there been

*Part of an address delivered before the American Mining Congress.

any prosecution of the railroads for violations of the Sherman law because of collusion of fixing rates? And yet, everyone knows that they are just as flagrant violators of the Sherman act as any other class of corporations in the United States. Are the freight rates the same for different roads between any two points? Are the passenger rates between Philadelphia and Chicago identical on all roads? Can you do better in price by traveling over the Pennsylvania than over any other road? The rate is the same providing the speed is the same. How does it happen that the roads all got together? Just by Providence I suppose. It was doubtless by a providential act that these rates were fixed identically upon all the roads, under the same conditions, all over the country.

Why is it that nobody proposes to indict the railroads for collusion? Simply for the reason that the rates which they can charge are controlled by commissions, national and state. Nobody any longer wishes to make them further trouble, because the public is protected by its commissions. The railroads are just as amenable to attack under the Sherman act as any other combination in the United States, but when the railroads are giving reasonable rates, and are competing in giving reasonable service, even if the law is on the statute book and is the hallowed thing that has been described—the sense of official justice is such that they are not attacked in the courts. Will the Attorney General of the United States or the Attorney General of this or any other state bring suit against the railroads for conspiracy in fixing rates when the public is properly protected? I have not heard of such a proposal.

However, it is a wrong condition when we have on the statute books a law of a kind which requires the officials of justice to close one eye whenever they pass by the men in control of one group of industries and at the same moment see other men not one whit more guilty. We ought to remedy this condition so that honorable business men shall not be in the unfortunate position of being technically violators of statutes which it is not advantageous from the public point of view to enforce.

The Sherman Act

In regard to the Sherman act, it has been assumed that its only violators are the great combinations. This assumption is made in practically all discussions of the question. The 'Steel Trust,' the 'Tobacco Trust,' and a few other large combinations are mentioned; and it is supposed that the small business men and the small producers are not acting in violation of the law. But the principle of coöperation which the Sherman act tries to suppress extends from the great industrial centres like Philadelphia to the country cross-roads. Does it make any difference here in Philadelphia, the home of anthracite, whether one buys anthracite of one retail dealer or another? It doesn't make any difference in the country cross-roads either. The price is just the same from all the dealers in the same locality. The same is true of ice, the antithesis of anthracite, and is also true of all standard articles. The principle of coöperation has extended from the great manufacturers and the great dealers of the large cities to the

small manufacturers and small dealers of the small cities and even villages. All are coöperating in the same way; the principle is the same for the large and small man; one is violating the law just as certainly as is the other. I am willing to stand for enforcement of law when the law is enforced alike for all; but when somebody is picked out because he is in the front seat, or because it is good politics to attack him, and ninety-nine or nine hundred and ninety-nine are allowed to escape, I say that it is a profoundly immoral situation.

Farming Trusts

The cranberry growers of Cape Cod, New Jersey, and Wisconsin, sell about 90% of their products through an agency down in Hudson street, New York. Similarly, many products of the farmers, illustrated by cotton, citrus fruits, and others, are marketed through coöperative selling agencies. Have we heard of the Attorney General prosecuting these farmers? Congressmen understand the situation, and at their two recent sessions they attached to the Sundry Civil bill a clause containing an appropriation of \$300,000 for the enforcement of the anti-trust laws, which included the provision that none of this money should be spent in prosecuting combinations or agreements of labor, nor spent for the prosecution of producers of farm products and associations of farmers who coöperate and organize in an effort to and for the purpose of obtaining and maintaining a fair and reasonable price for their products. The purpose of this provision is clearly to make the Sherman law class legislation by indirection and in effect to prevent equality before the law of the manufacturer as compared with the farmer. And some of the smarter state legislatures have seen the situation and in order to prevent the farmers from being hit by their anti-trust bills exempted the products of the lands so long as in the hands of the producers. The state legislatures, like Congress, saw that the farmers have so many votes that they have to be dealt with gently when they form a trust. But some of the state laws got into the United States courts, and these courts promptly declared these exemptions unconstitutional as being special legislation. I venture to predict that it will not be so popular a political game to shout, 'Bust the trusts,' when the farmers understand that their trusts are also to be 'busted.' No more pernicious or immoral legislation was ever passed by Congress or by the states. The principles of justice in regard to trusts and combinations are alike for the manufacturers, the farmers, and the laborers. In this country we have not a special situation which concerns a few men, but a general, irresistible impulse. There is just as close-riveted an arrangement between the three ice-men in the country town as there is in steel; and any solution of the problem of combination, if it be a just solution, must be applied not only to steel and tobacco, but to the small tradesman, the farmer. Just as certainly as the great combinations are violating the Sherman act, as I have no doubt many of them are, so are the small aggregations of wealth violating state anti-trust statutes. This general violation of the trust laws national and state is the problem that we have before us.

Holdings of the Hollinger Reserve Mining Co., Ltd.

By AN OCCASIONAL CONTRIBUTOR

The Hollinger Reserve Mining Co., Ltd., is incorporated under the laws of the Province of Ontario and capitalized at \$2,000,000, divided into 400,000 shares at a par value of \$5 each. The Company owns claims H.R. 9, 25 and M.E. 44, 45, and 46 in the township of Ogden, Porcupine mining division, Ontario.

The country is slightly rolling and heavily wooded in this vicinity, mostly sandy plains with one rocky knoll near the Mountjoy or Foolham river. The country rock is Keewatin greenstone, intruded to the south by a quartz diorite. A belt of schist, 120 ft. wide at the surface, resulting from the metamorphism attendant on the diorite intrusion, lies at the contact of the diorite and greenstone. This belt of schist has been found to be 134 ft. wide at the 100-ft. level and 240 ft. wide at the 200-ft. level. In this belt of dark gray, fine grained, and compact schist, a series of five parallel veins have been formed, ranging from two to six feet wide on the surface and striking 15° N. of E., and with a dip of 5° from the vertical to the north. These veins, in many places, have no regularly defined walls and the gold content diminishes as the distance from the pay streak increases. The veins consist of quartz in distinct stringers as well as in bunches, irregularly distributed throughout the schist, the whole being impregnated with iron pyrite, some copper pyrite and a little mispickel, in spots. Free gold has been found in a great many places along a definite rich pay-streak on the surface of No. 1 vein. On the 100-ft. level free gold can be traced almost continuously along the entire 70 ft. which has been driven on the pay-streak of this vein, and can be seen in numerous places along the pay-streak on the 200-ft. level.

On the 100-ft. level, the vein assays average \$51 for the 70 ft. driven, with an average width of 4 ft., while on the 200-ft. level the average assay for the 168 ft. driven was \$27, with an average width of 5 ft. The vein at this level has a total width of over 12 ft. The eastern face of the drift at the 200-ft. level showed assays of \$47, for the entire face, which is over 5 ft. wide, and the western face showed assays of \$34 per ton. The five parallel veins are all being developed at the 200-ft. level, where the principal development work is now being done, after cross-cutting the entire vein system at the 100-ft. level. No. 2 vein averages 4 ft. wide on the 100-ft. level and can be seen in the shaft for the entire distance between the 100 and 200-ft. levels. It has been driven for a distance of 140 ft. on the 200-ft. level and shows assays averaging \$6. The drift is 6 ft. wide.

No. 3 vein merges with veins 4 and 5 on the 200-ft. level, all of which show assays ranging from \$5 to \$10 over widths averaging 5 ft.; on the 200-ft. level. The united veins are 5 ft. wide and average \$8 per ton. From a depth of 65 to 87 ft. in the shaft, a series of quartz stringers showing considerable free gold traversed the shaft dipping toward the No. 1 vein. These stringers gave assays averaging

\$57 per ton across the width of the shaft.

A fault was encountered at the 200-ft. level which will cut veins No. 1 and 2 at a depth of between 200 and 300 ft. and which let in a lot of water. The shaft is making 14 ft. of water per day, and to pump this, two sets of Cameron duplex pumps have been installed. In case one set stops, the other set is ready for immediate operation, thus obviating any vexatious delays.

Practically all the development has been done on the rocky knoll, where during the winter of 1911-1912 a series of diamond-drill holes were drilled to a depth of 350 ft., and the results were so satisfactory that a shaft was commenced on June 15, 1912. A Rand compressor of 585 cu. ft. capacity has been installed with two boilers of 60 hp. each. The equipment has been increased until now the Company has a complete set of buildings, comfortable offices, manager's house, cooking and sleeping quarters, shaft house, well equipped blacksmith shop and power house, and a comfortable dry house for the men, with hot and cold water in the baths. The 215-ft. shaft is equipped with bell, and air signals, and the cage with an automatic safety device. On the 100-ft. level, 290 ft. of driving and cross-cutting has been done, and on the 200-ft. level, 650 ft., where development is being rushed preparatory to the erection of a mill. The property has just passed into the hands of the Lewisohns, who are to finance further development and receive in return an interest in the Company.

Costs at the Great Fingall Mine

During 1912, there was treated 71,603 tons of ore at this company's mill in Western Australia, at the following cost:

	Cost per ton.
Ordinary development	\$0.76
Ore extraction:	
Breaking ore	1.14
Filling stopes	0.09
Tramming and raising	1.32
Total mining	\$3.31
Ore treatment:	
Rock breaking	\$0.14
Ore transport	0.05
Milling	0.56
Concentrating	0.04
Filtering and fine grinding concentrate.....	0.08
Fine-grinding sand	0.30
Cyaniding by percolation	0.21
Slime (vacuum filtration)	0.22
Precipitation and smelting.....	0.06
Disposal of residue.....	0.15
Sampling custom ore	0.07
Treating custom concentrate	0.04
Total treatment	\$1.92
Less receipts from custom ore	0.21
Net treatment	\$1.71
General expenses	0.60
Bullion expenses	0.07
Total expenditure	\$5.69

During September the Elmore vacuum plant at the mines of the Sulitjelma company, Norway, produced 1163 tons of copper concentrate.

Ore Formation and Country Rock

In a recent report to the Kalgurli Gold Mines, Ltd., Malcolm Maclaren cites an especially clear and interesting instance of the effect of country rock on the value of ore in veins.

"The productive lodes and orebodies of Kalgoorlie," he says, "lie almost entirely in a broad dike of quartz-dolerite that, when uninfluenced by faulting, dips westward at 65°. The general effect of the faulting (all of which has taken place prior to ore deposition) has, however, been to give the dike a somewhat flatter dip. The dike strikes north and south, and is intruded through older greenstones that are everywhere barren except at and near their contact with the quartz-dolerite. Since the dike dips west, the underlying older greenstone (in this case calc-schist) lies beneath all the mines on the eastern side of the Kalgoorlie field at depths varying with their respective distances from the eastern margin of the quartz-dolerite. Naturally, also, since the lode channels of the eastern side of Kalgoorlie are approximately vertical, they pass ultimately in depth into the underlying calc-schist.

"The experience of five important mines is identical and to the effect that beyond a certain short distance (generally less than 100 ft.) beneath the quartz-dolerite, lode channels fail to carry ore. In gaining this experience, a sum certainly not less than £345,000, and probably not more than £400,000, has been expended in actual driving, sinking, and cross-cutting in the calc-schist. One mine, vainly hoping against hope, has during the past three years spent £48,000 in this pursuit, reaching a depth of 500 ft. beneath the contact, but recovered practically no profitable ore. In this instance the lode was far stronger and better defined than the ore channel of the Kalgurli mine, rich though the latter has been. Nothing better than a few tons of low-grade ore has ever been obtained from the calc-schist once the favorable quartz-dolerite has been left behind.

"On the other hand, a favorable locus for ore is in the calc-schist immediately beneath the quartz-dolerite. It was here that the famous Oroya 'shoot' occurred. The depth of this zone of possible ore in the calc-schist may be placed about 100 ft. below the quartz-dolerite, though no large body of ore has ever been found more than 60 ft. beneath, and, as already indicated, some of the lodes that have gone down into the calc-schist have been far stronger and better defined than any ever shown in the Kalgurli mine. Experience has further shown that as orebodies and lodes approach the lower margin of the quartz-dolerite, there is generally a marked diminution in the strength of the orebody and in its value. The height of this zone of impoverishment above the plane of contact may vary from a few feet to 200 feet."

The total quantity of gas produced in New York in 1912 is estimated by E. W. Parker, of the U. S. Geological Survey, at 8,625,979,000 cu. ft., valued at \$2,343,379. On the other hand, the consumption of gas in New York during the year was 16,927,598,000 cu. ft., valued at \$4,886,821, an average price

of 28.75c. per 1000 cu. ft. The larger proportion of the gas used in New York is consumed for domestic purposes, the estimated amount so used being 15,329,811,000 cu. ft., valued at \$4,583,414, an average price of 29.90c. per 1000 cu. ft. Only 1,597,787,000 cu. ft., valued at \$283,407, was consumed in the industries.

Smelting Works at Grand Forks, British Columbia

The following notes are from the report of the superintendent of smelters, W. A. Williams, to the Granby Consolidated Mining, Smelting & Power Company.

The blast-furnace department ran steadily for the full year, and averaged 7.94 furnaces in continuous operation for 365 days. The furnace department smelted:

	Tons.
Granby ore	1,264,690
Foreign ore	15,179
Converter slag and matte	48,078
Flue dust	4,422
Average per cent of coke used per ton of ore, 13.36.	

From the tonnage standpoint operations were good, and the tonnage for the year was 1,279,869 tons of ore, against 739,519 tons for 1912 and 984,346

GRANBY SMELTER, GRAND FORKS, B. C.

tons in 1911. The average smelting cost for the year was \$1.214, as against \$1.256 in 1912. All the machinery in this department is in good repair and being operated to full capacity at the present time.

In the converting department costs are lower this year per ton of ore, and the machinery is all in good repair. This department produced 22,683,181 lb. of copper in 1913, as against 13,226,360 lb. in 1912 and 17,858,860 lb. in 1911. There was 34,500 tons of 32.9% matte handled.

Taking the year as a whole from the operating end it shows very well. A larger tonnage was handled than in previous years, and higher silica slags have been produced with less copper loss. Costs are less than any previous year since operations began. The railroads handled all material satisfactorily, and there was no difficulty with labor.

The total value of the mineral production of Illinois in 1912 was \$123,068,867, of which coal represented \$70,294,338.

Depth of Shafts at Cripple Creek

The following list has been compiled by the *Cripple Creek Times-Record*, and will serve as an index of the present scope of operations at Cripple Creek.

Battle Mountain: Ajax Gold Mining Co.'s main shaft, 1228 ft. deep. Granite Gold Mining Co.'s Gold Coin shaft, 1225 ft.; two levels are now submerged by seepage water. Portland Gold Mining Co.'s No. 1 shaft, 1250 ft., in course of sinking to depth of 1600 ft.; No. 2 shaft, 1600 ft.; and No. 3 shaft, 1200 ft., has been abandoned. Stratton's Independence, Ltd., main shaft, 1430 ft. Strong Gold Mining Co., 1200 feet.

Bull Hill: Bull Hill not only has the deepest shaft in the district, but also the greatest number of shafts sunk below the 1200-ft. point. Acacia G. M. Co., South Burns shaft, 1200 ft. Blue Bird G. M. & M. Co., main Johnson shaft, 1750 ft., and now sinking to water-level, probably 100 ft. deeper. Findley Con. G. M. Co., main shaft, 1387 ft. Golden Cycle M. Co., main shaft, 1700 ft.; Theresa mine shaft, 1200 ft. Gold Sovereign M. & T. Co., main shaft, 1100 ft. Isabella Mines Co., Lee shaft, 1275 ft.; Empire State shaft, 1220 ft. Last Dollar G. M. Co., main shaft, 1200 ft. Stratton's Independence M. & D. Co., American Eagles shaft, 1500 ft.; John A. Logan shaft, 1500 ft.; and Orpha May shaft, 1500 ft. Trilby Mines Co., main shaft, 1120 ft. United Gold Mines Co., Wild Horse shaft, 1225 ft. Vindicator Con. G. M. Co., main or No. 1 shaft, 1630 ft.; Hull City shaft, 1265 ft.; Lillie shaft, 1526 ft., has been abandoned.

Beacon Hill: El Paso Con. G. M. Co., No. 1 shaft connected with the Roosevelt deep-drainage tunnel at 1332 ft. from surface. Henry Adney G. M. Co., Maid of Orleans shaft, 900 ft. Gold Dollar Con. Mines Co. has the deepest shaft on the opposite or eastern slope of Beacon hill in the Mable M. shaft, 994 ft. deep.

Carbonate Hill: Elkhorn shaft, 450 feet.

Globe Hill: No shaft in this district has attained a depth of 1000 ft. The two deepest shafts are on properties of the Stratton estate. The Plymouth Rock, between 800 and 900 ft., is inactive and is reported in bad working condition. The Deerhorn shaft, active and producing, is 650 feet.

Gold Hill: The shafts to attain a depth below 1000 ft. on this hill are the Anchoria-Leland, 1200 ft.; the Moon Anchor, 1100; and the Half Moon and Conundrum are below 1000 ft. The Mary McKinney drifts will cut under the summit at a depth of 1700 feet.

Galena Hill: The deepest shaft on this hill is that on the Sunshine mine. The property is now active. A depth of 450 ft. was attained in the incline sunk on this property.

Guyot Hill: The Katinka G. M. Co.'s shaft on the Chicken Hawk mine, now 1020 ft. deep, is being sunk by the Progressive Mining & Development Co. to a depth of 1250 feet.

Ironclad Hill: Jerry Johnson M. Co., main shaft, 975 feet.

Mineral Hill: Addie C. shaft, 485 ft. The property is inactive.

Poverty Gulch: Gold King M. Co., main shaft, 1007 ft. Abe Lincoln mine, of the Stratton estate, 925 ft., with drifts into Womack hill in excess of 1200 ft. from surface.

Raven Hill: Cresson Con. G. M. & M. Co.'s main shaft is 1350 ft. Elkton Con. M. & M. Co.'s main shaft, on the Walter claim, 1200 feet.

Squaw Mountain: The two deepest shafts are the Climax, 400 ft., and Nellie V., 325 feet.

Tenderfoot Hill: Grafton G. M. Co., Hoosier shaft, 650 ft.; Mollie Kathleen shaft, 1000 feet.

Outside districts: No shafts have been sunk to a depth of 500 ft. on Copper or Rhyolite mountains, Signal hill, or in any of the outlying districts.

The Deep Drainage Tunnel, with its portal at an altitude of 8033 ft., attained its greatest depth under the summit of Beacon hill at an approximate depth of 1500 feet.

Electric Blasting

By CHARLES S. HURTER

It is not at all improbable that electric blasting in the stopes after the men have left the mine, followed by proper ventilation, will in part solve the dust problem in South African mines. A good air current should remove the dust that is fine enough to pass through the respirators worn by the men, but it is very doubtful whether it will be possible for the men to work with safety at any time without the use of respirators.

Electric blasting from outside the mine is a comparatively easy matter. This problem was worked out originally at Castlegate, Utah, at a mine of the Utah Fuel Co. and the method has since been adopted with great success at a large number of the Western coal mines. The advantages of electric firing are the entire absence of smoke from burning fuse, the greater safety due to the absence of premature and hang-fires, the reduction of the number of misfires, particularly in wet places, the absence of burnt charges, and the fact that everybody is in a safe place when the shots are fired.

At the present time I doubt if electric blasting will be introduced for blasting drifts owing to the delay due to the fact that only one set of holes can be fired at a time. In the stopes there will probably be a large number of instances where more ground will be broken by a line of holes blasted together by electricity than would have been accomplished by shooting singly by means of blasting caps and fuse. However, there will be a number of instances where, while more ground is broken by electric firing, it will be in larger pieces and require a greater expenditure of explosives for block-holing and mud capping.

In order to get rid of as much dust as possible, the ventilating current should be established at its maximum speed through the working places before and during blasting, so that the maximum amount of dust will be carried out of the mine. In short, it appears that the use of electric blasting after the men have left the mine would reduce the amount of bad dust in the working places provided these working places have the proper ventilation.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

An English View of Mexican Conditions

The Editor:

Sir—I believe that the people of the United States are badly served with news as to real conditions in Mexico. That is to say, there is a tendency on the part of the border newspapers to paint matters in a very unfavorable light for the present Mexican government, and I do not think that the situation is quite so bad as these papers would have one believe. However, there is no doubt that things are bad in the north of Mexico, and in some parts of the south they are not too good. I am exceedingly dubious as to whether any government made up of Mexicans can ever be equal to handling a country of such undeniable wealth and resources. The chief difficulty is that the country is ahead of the people, and foreign capital is almost wholly responsible for its development, having taken all of the important enterprises out of the hands of the Mexicans. In consequence, their cupidity is aroused and they want to have the profits that reward the zeal and enterprise of the foreigner. They do not realize that their only hope of salvation is to become patriotic and industrious. On the contrary, they have sunk more and more into a state of degeneracy and uselessness, and unless something unforeseen happens, in my opinion, the United States sooner or later will be compelled to take a hand in the matter. A recent trip to Mexico convinced me more than ever that Mexico is the greatest mineral country in the world, and nothing—not even the Mexican people and the poor government—can stem the developments that are bound to take place there.

It seems possible that Huerta has the ability to handle the rebel trouble and there is no doubt but what he has sent many an aspiring bandit to an early and hurried grave. Should it be quite clear that Huerta has the ability to handle the country single-handed, it will be difficult for the jingo element in the states to show any good reason for intervention. That is to say, that they will not be hurried into an intervention whose sole object will be to further the financial schemes of certain unscrupulous interests who only represent a very small percentage of the people of the United States. It may be, of course, that intervention will become necessary for reasons other than those at present put forward, and it may be that those reasons will be strong enough to carry the support of all of the other nations in such a step, but if America is rushed into hasty action without reasonable grounds, it will do her incalculable harm.

I have always had the fear that the Mexican people are too far behind the development of their country to govern it satisfactorily, because those developments have been brought about by foreign people with foreign capital. The people of Mexico

have stood aside and watched the progress made, but they have neither done any work nor learned how to do it. For these reasons it may be that in view of the astonishing resources of the country, its further development may become too great a thing for any Mexican government to handle unassisted. For the protection of these great interests America may have to take some active step for her own protection and that of her European friends. This kind of intervention, however, is not yet called for, and I am one of those who hopes that America will pursue a policy of the greatest forbearance and that she will only take the decisive step suggested, when there is absolutely no other alternative.

H. S. DENNY.

London, September 2.

A Geological Survey of China

The Editor:

Sir—Your editorial in the issue of June 28, 1913, regarding the proposed Geological Survey for China is deserving of serious consideration from anyone interested in that great country and its wonderful people. I say wonderful, because the Chinese are probably the most interesting, if not in some respects the greatest nation in the world. They have always been an essentially agricultural race, possessing the virtues and strength of character peculiar to a nation 90 per cent of whom are tillers of the soil. The two fundamental resources of the earth are the products of its soil and mineral deposits. Although it has been known for many years that China possessed great stores of mineral wealth, up to the present time, they are practically untouched and undeveloped. The Chinese have lived for many centuries chiefly from agricultural products. Hence the beginning of her mineral development marks an epoch of the utmost importance to this nation and probably in time to the world at large.

The creation of an efficient, well equipped, and generously financed geological survey is, beyond doubt, a proper and wise step, but its efficiency and success will be very seriously menaced if it be placed in the inexperienced native hands. Not that there are not plenty of intelligent and well educated Chinese to call upon, but that these men, be they ever so brilliant in mind and administrative ability, are liable to be devoid of the requisite technical training and experience. The Chinese who have received technical educations in our Western schools are, most of them, too young to have had much practical experience. It will, of course, be pointed out that the Japanese have developed their mineral resources by first employing Western engineers and geologists, then as their own people became educated replacing them by natives. But it must be remembered that Japan is a small country as compared with China, and that her mineral resources are immeasurably inferior; moreover, those who are familiar with this development in Japan know that it has not always been well done and that needless waste resulted.

In a general way, the geologic conditions of China are fairly well known through the researches of

Pumpelly, von Richthofen, Bailey Willis, and many European geologists, especially Le Clère and Du Clos. The economic character of these researches was necessarily limited, for investigations of this kind demand close and painstaking study that will require many years of continuous and skilled effort. To delegate such work to the teaching staff of an institution of learning or a commission composed of academicians, be they native or foreign, would be folly. Mining is a commercial business; it must profit its backers or else it ceases to be mining. It is to be feared that men who are simply technologists may prove unsafe advisers because, as a rule, they lack the business experience necessary to properly organize successful mining operations. The Chinese in some respects are unrivaled merchants and traders. In other ways they are children when it comes to coördinated combinations such as joint-stock companies, which are absolutely necessary to carry out engineering undertakings. This, at least to some degree, explains the slowness with which mining development has progressed in China. It has frequently been ascribed to the lack of railroads, political disturbances, and the ignorant superstition sometimes exhibited by the natives of all classes. No doubt such influences have had some effect, but they are slight as compared with the lack of coöperation among the natives, for they naturally distrust themselves in matters not fully understood.

The geologic conditions of the Yangtse basin and river valleys tributary to it, resemble in a general way those of Pennsylvania, Ohio, and western Virginia, in that they contain great stores of coal and iron. Today the great steel industries of Pennsylvania could not exist without the rich Lake Superior or foreign iron ores. Pennsylvania, as in fact did England, commenced her iron industry with the comparatively lean and inferior local ore, but it grew and thrived because of the vast supplies close at hand of cheap and excellent coking coal and anthracite coal. Being once established, it was cheaper to bring the ore to the fuel than the fuel to the ore, hence our present conditions wherein comparatively little local ore is used when the freight rates are sufficiently low to make possible the purchase of richer ores from greater distances.

Turning now to China, it may be noted that her one large and prosperous steel industry is at Hankow, a city at the junction of the River Han and the great Yangtse, both rivers draining large areas of coal territory. Eighty miles below Hankow and 18 miles back from the left bank of the river at Tayeh there are some excellent hematite deposits which are now extensively worked. With this exception, as far as I know, no high-grade iron ore deposits have yet been developed in China. The fact that China has vast stores of coal and will doubtless eventually develop an abundance of iron ores, is one of tremendous importance to the whole world; for, as we know, a coal and iron supply is the backbone of all modern industry, everything else being subservient to it, and by comparison all other forms of metallurgical and mining industry palling into significance. Without fuel, steel is impossible, and, lacking that, no railroads, battleships,

or other essentials to modern civilization—or savagery if viewed from the battleship standpoint.

In dealing with oriental mining affairs, it is important always to bear in mind the great difference in labor conditions between those in America and those existing in China. Properties which would not pay in the United States may be made to yield a large profit with the cheap Chinese labor: but even so, there can conceivably be circumstances under which this cheap labor may be a delusion and a snare. Where skill and high efficiency count, as in most of our Nevada and Arizona mines, cheap labor would in the end be expensive; but when it is a matter of simple brute force, skill is ever at a disadvantage. Foreign investments in Japanese mining have been almost without exception disastrous.

If the Chinese are well advised, their National Geological Survey or Bureau of Mines, whichever it may be termed, will be organized by experienced American or British mining engineers, and at first will be largely composed of well trained men, having directly under them picked natives who have had some technical training. In the course of time, the Chinese would naturally replace the foreigner, just as in the Chinese custom service so efficiently organized many years ago by Sir Robert Hart, and which has proved an invaluable mainstay through the stormy and trying days which have overtaken China during the last twenty years.

Japan for some time past has been drawing a large part of her iron ore supply from China and is now beginning to import Chinese coal. This is certain to continue in a steadily increasing volume, for Japan is too poor in resources to meet the demands of her artificially stimulated industrial propaganda. The great steel works at Wakamatsu was for years conducted by the Japanese government at a loss, but now is said to yield some direct profit. I believe much the same may be said of the Han-Yang steel works at Hankow, which was scandalously mismanaged when left wholly in untrained and inexperienced Chinese hands.

China has many other mineral resources besides coal and iron. Practically all the metals are found in her vast territory, but as a rule it would seem that her metal deposits are lean as compared with other countries; this disadvantage, however, is more than offset by an unlimited supply of cheap labor and fuel. Deposits which would be unprofitable where labor is dear could be made to pay in China under such extraordinarily favorable conditions.

As time goes on, rich deposits all over the world are being rapidly exhausted: a difficulty often, at least temporarily, overcome by the use of clever labor-saving devices. It seems likely, however, that there must be a limit or point where mechanical efficiency cannot be made to equal cheap Oriental labor, and competition with the Chinese will eventually become hopeless unless we lower our standards of living or they raise theirs. This theme is a fascinating one, grave and serious menace though it be. Americans cannot expect, even if they desired, to lower their ways of living; but if they are to be the teachers of the Chinese in their com-

ing industrial development, they may hope to lift their standards of existence to a plane somewhat nearer the American.

F. LYNWOOD GARRISON.

Andover, Massachusetts, August 26.

[Our correspondent overlooks the most important factor which now restricts mining development in China, namely, lack of capital. The public temper will not permit the granting of more concessions to foreign companies, foreign investors will not risk their money in mines under Chinese control, and the demands for capital within China are so great that the native investor can readily place all the funds at his command. Naturally, he prefers trade, at which he is an adept, rather than mining, with which he is rather unfamiliar, beyond knowing that several companies financed by Chinese and managed by foreigners have been lamentable failures. Doubtless the proposed geological survey will also be greatly hampered in its work by lack of funds, if it is finally launched. While agreeing in general with our correspondent's view, it is only fair to point that the Chinese administration doubtless feels that a single experienced foreigner would cost, in salary and expenses, as much as a half dozen Chinese, only to go home at the expiration of a contract, taking most of his knowledge with him, and that, having waited 'ten thousand years' to develop her mineral resources, China can afford to wait until a native staff has been trained for the purpose. Whether they will ever receive that training without foreign supervision is 'another story.'—EDITOR.]

Grinding-Pan Practice

The Editor:

Sir—I am glad to be put right by Mr. von Bernewitz as to my misinterpretation of the capacity column of his figures on grinding-pan practice at Kalgoorlie. His explanation, however, calls attention to the vague and indefinite meaning of the words 'slime' and 'sliming' as used in mill practice in different parts of the world. Here is a case in which a distinction is made at the 150-mesh screen in the case of the pan feed, but at the discharge the whole product is regarded as being 'slimed' although in two mills but 52% will pass the same screen.

The average daily tonnage, then, of 5-ft. pans in the district, grinding to 150 mesh, is:

	Tons.
Roasted ore	7.18
Roasted concentrate	16.20
Following stamps	7.97

This seems to be good work considering the fact that the pans do not have the advantage that a tube-mill usually has, a classified feed, and also that the particles not ground to 150 mesh are greatly reduced in size.

As a practical matter, this question is new to me, but interesting, as a pan that has some faults in its construction is now working under my observation. As far as I have studied the problem, it seems that the capacity of a pan depends principally upon getting the greatest possible number of grains of sand under the shoes, and this is best accomplished by crowding the grains as closely to-

gether as possible in a pulp as thick as consistent with circulation, and containing the least possible amount of material already ground. The pan of which I speak has been lately fed with pulp containing 29 to 31% moisture. This has resulted in a large increase in capacity.

R. H. Richards, in discussing amalgamating pans, refers to this circulation outward through the spaces between the shoes, up the sides, and returning inwardly. It consists of a vortex movement precisely like a 'smoke ring,' but is compounded with the whirling motion of the pulp, the latter movement being of no particular advantage as far as grinding is concerned. The shoes, acting like the vanes of a centrifugal pump, are sure to set up and maintain this movement, and that renders the usual plowshare-shaped wings or deflectors entirely unnecessary. Also, as Mr. von Bernewitz points out, there is no advantage in a device for centre feeding. The feed will go to the centre and down to the shoes in any event. It thus seems that pans can be somewhat simplified.

In view of this vortex movement of the pulp in a grinding-pan running at any ordinary speed, I cannot conceive of a fair degree of classification occurring at the overflow lip, and this condition would seem to make outside classification of the pan discharge quite necessary. Classification would undoubtedly occur at the lip to some extent if the pulp were thin enough and the lip arranged for the return of the sand to the pan, but the disadvantage of thinning the pulp would seem to more than offset the advantage of this method of classification. I look for improvements in practice that will make the grinding-pan a very efficient machine.

JOHN RANDALL.

Atlantic City, Wyoming, August 27.

The Editor:

Sir—In reply to John Randall's further contribution to this subject, I would say shortly that the terms 'slime' and 'sliming' are used in a vague way in the many mining districts of the world, but simply indicate the point at which further grinding is unnecessary to obtain the best recovery of gold and silver in the ores; the duty of pans at Kalgoorlie is good; the use of wings or deflectors in a pan used for complete sliming is an advantage; a properly constructed overflow lip does classify the pulp to a large extent, but with a classifier in closed-circuit with a pan, the pulp can be kept thick and the capacity increased, although there is a point which would need close observation, namely, is it better to dispense with the overflow lip and give the classifier all of this work, or let the pan classify in the lip and produce a final slime also? Mr. Randall could no doubt give us some interesting figures on screen analyses of the feed, pulp in the pan and overflow lip, and final slime.

M. W. VON BERNEWITZ.

San Francisco, September 10.

[Mr. von Bernewitz's article is bringing out some useful discussion and it occurs to us that the experience of those who have used pans in clay-working industries would be of interest. Can any reader supply data?—EDITOR.]

Special Correspondence

MELBOURNE, AUSTRALIA

MINERAL PRODUCTION OF AUSTRALIA IN 1912

Statistics of Australian mineral production recently published call attention to the fact that there are two sets of reliable mineral statistics compiled annually for Australia. One is the work of the Commonwealth statistician, G. H. Knibbs, the other is the work of the editor of the *Australian Mining Standard*, E. H. C. Oliphant. The latter makes a strong feature of securing uniformity for the returns from the various states of the Commonwealth, and for purposes of comparison his work is therefore the more valuable. Although in a series of articles published during the last year or two, he agreed in favor of the inclusion of figures relating to any and every branch of the mineral industry, admitting the returns for building stone, brick clays, sand, cements, slates, and lime, he found that to effect any fair comparison between the states he would have to omit all these, because some states failed to give any returns regarding them. He has been obliged to omit salt for a similar reason. His figures, therefore, vary from those of the Commonwealth statistician, who includes, for example, salt, in the South Australian data and does not include it in the Victorian returns, because it is unobtainable. There is another great difference between them, and in regard to this there can be little question that the journalist is right; whereas Mr. Knibbs, following the lead of the New South Wales Mines Department, gives the net value of the product of the silver-lead mines of the state, Mr. Oliphant gives the gross value. His argument is that it does not matter where the separation of the metals is conducted, and that the product is entirely from New South Wales, even if much of the profit accrues to Germany. The Commonwealth statistician's returns, except in this one particular, approximates fairly close to those of the *Australian Mining Standard*, since he also omits returns relating to building stone, brick clays, gravels, cement, and slates; but he is much less consistent, in that, while he includes the limestone used for fluxing, he does not include the limestone used for other purposes. Mr. Oliphant agrees that this is as unreasonable as it would be to restrict the ironstone figures to so much of the mineral as is used for fluxing purposes.

Mr. Oliphant's figures for the year 1912 have now been made available. They show the following totals for the various states of the Commonwealth:

State.	Value.	Compared with 1911, %.
New South Wales	\$ 57,577,328	+12.7
Victoria	11,306,776	— 5.4
Queensland	20,120,923	+14.3
Western Australia	27,937,004	— 5.7
Tasmania	7,243,485	+10.7
South Australia	2,548,956	+37.0
Northern Territory	280,427	— 2.6
Total	\$127,049,979	+ 6.3

To this may be added the figures for Papua or New Guinea, \$340,979, a 5.6% decrease.

The chief items are set out as follows:

Metal.	Value.	Compared with 1911, %.
Gold	\$48,211,696	— 7.3
Silver and lead	23,652,330	+17.2
Zinc	8,567,326	+24.8
Copper	15,783,020	+26.3
Tin	6,542,611	+11.6
Coal	22,215,323	+11.3

New South Wales produces 100% of the zinc output, 93.3 of the silver-lead, 25 of the tin, 17.8 of the copper, 83.4 of the coal, and 79.4% of the iron; Victoria 20.5% of the gold; Queensland, 14.9% of the gold, 52.2 of the copper and 27 of the tin; Western Australia, 54.9% of the gold; Tasmania 40.3% of the tin and 13.5% of the copper, and

South Australia 14.2% of the copper and 15.4% of the tin.

In yet another table the *Australian Mining Standard* shows how each state's output is made up. From this it is seen that 32.2% of the total value of New South Wales' mineral production comes from coal, 23% from lead, 14.9% from zinc, and 14% from silver; 87.5% of Victoria's from gold and 11.1% from coal; 40.9% of Queensland's from copper and 35.6% from gold; 94.6 of Western Australia's from gold; 36.2 of Tasmania's from tin, 29.4 from copper, 20.6 from silver and lead, and 10.8% from gold; 86.6% of South Australia's from copper; 46.7% of Northern Territory's from tin and 29.2% from gold; 86.2% of Papua's from gold, and the remaining 13.8 from copper. Of the Commonwealth totals, gold provides 37.9%, silver and lead 18.6%, zinc 6.7%, copper 12.4%, tin 5.1% and coal 17.4; iron being the only other constituent of any consequence.

JOPLIN, MISSOURI

PROSPECTING TODAY IS AT MUCH DEEPER LEVELS THAN FORMERLY.—NEW MILLS OF THE THOMS STATION DISTRICT.

On one 20-acre lease in the Spring City camp, four miles south of Joplin, seven churn-drills are at work. This is no doubt the greatest number of drills ever operated simultaneously on such a small tract of land. Lee and Bridgeford, of Kansas City, Missouri, are doing the work, they holding a lease from J. W. Allen. They recently purchased this lease from the Frank A. Malang Mining Co. and will prospect the property in a thorough manner, as the ore deposits of this particular part of the district are very irregular. Rich mineral may be found at one point, while a hole sunk five feet away in either direction might penetrate barren rock. The prospecting also will be carried to a depth of 250 to 300 ft., former work on the land having been confined to the shallow ground, no work having been carried below 100 ft. Seven shafts are into ore on the tract at a depth of 90 to 100 ft., and a dump of 200 tons is on the surface. Some of the ore from these shafts was hand jigged by former operators, but the bulk of the mineral produced was from comparatively hard ground, and milling will be necessary. Not only at the property referred to, but on numerous other tracts, prospecting operations are being carried to deeper ground than ever before. J. M. Short has four churn-drills at work on an 80-acre lease of the Ragland land, northeast of Joplin. Work on this property was conducted down to 150 ft. Mr. Short has four good holes into disseminated ore at a depth of 240 ft. He will start a new shaft soon and plans the construction of a mill.

At Thoms Station, three miles north of Joplin, mining activities are in evidence on every hand. The ore occurs in soft ground, requiring timbering to support the roofs of drifts. The ore carries both sphalerite and galena, although the two are rarely found associated, as is so commonly the case in other portions of the district. The Thoms Station mine, as a general rule, is either a producer of galena or a producer of zinc sulphide, while the Napoleon, a heavy producer of both minerals, is one of the exceptions of importance.

A number of new mills are being constructed at Thoms Station. One, the Pocatella, operated by Danglade and Robertson, is nearing completion. It will have a capacity of 150 tons per 8-hour shift. This mine is on a 10-acre portion of the Snapp land, and one shaft has been sunk into ore, two drifts being operated, one of which goes east, the other west, and a dump of several thousand tons is on the surface. The ore will probably yield 15% of zinc-sulphide concentrate containing 60 to 63% metallic zinc. The drifts are at a depth of 180 ft., are 15 ft. wide and 20 ft. high, with about 5 ft. of ore in the roof. No deep drilling has been done on this lease. The Ortt & Coats mill, also on the Snapp land, has just been completed. The ore is yielding 10% blende and is of lower grade than that of the Pocatella and contains some iron. The Vinegar Hill, another mill on the Snapp land, is operating on high-grade zinc sulphide. This property has 200 tons of concentrate in the bin which is being held for higher prices. The Home Development Co. is operating

the Betsy Jane mill and making a fair recovery. The Texas Mining Co. has started operation at a new mill west of the Home Development Co. The Kansas City Mining Co. has just completed a new mill in the east part of the Thoms Station district and has begun production. Many prospecting drills are at work.

North of Miami, Oklahoma, a large new concentrating plant has been completed by the Barnes & McConnell Mining Co. The property is on Tar creek, two miles north-east of the present Miami field. This is the first mill in the new field, but others are contemplated. The Commerce Mining & Royalty Co. recently organized with \$5,000,000 capital, has acquired leases on several thousand acres of land in the new field, and many churn-drills are at work. The ore deposits are found down to a depth of 300 ft. and are especially rich in galena. The Commerce company, formerly operated under the name of the Miami Royalty Co. Several other new mills are being constructed in the immediate Miami camp. One, the Lost Trails Mining Co.'s plant, will soon be ready for steady operation. Southwest of the main Miami field, Barnes and McConnell also have a new mill, which will be ready for operation in about a month.

TORONTO, CANADA

DECREASE IN ORE SHIPMENTS FROM COBALT.—QUARTERLY REPORT OF THE LA ROSA COMPANY.—DEVELOPMENT WORK AT THE PORCUPINE CROWN.

Ore shipments from the Cobalt camp have lately been greatly curtailed owing to the difficulty of marketing ore. Only three cars were shipped last week, which is the lowest record since 1905. The bullion shipments, however, amounted in value to \$97,689, which is somewhat above the general average. Nearly all of the bullion was from the Nipissing. The quarterly report of La Rosa indicates a decline in the ore reserves. Production for the first nine months of the year was valued at \$905,039 from high-grade ore, and \$80,546 from mill ore. R. B. Watson, general manager, reports that no accurate estimate as to ore reserves can be made at present, and no prediction as to the results of development work can be made with any degree of precision. The financial statement shows a surplus of \$1,882,833, including the value of ore in transit, at smelters, and ready for shipment. The directors are working on a comprehensive plan for the investment of the surplus. The North vein of the Seneca Superior has been cut on the Gould Consolidated at the 200-ft. level, where it averages 2 inches in width and is stated to assay 4965 oz. per ton. Three of the veins found on the bottom of Kerr lake when partly drained have been cut on the 140-ft. level, and prove on development underground to be mere seams which had been overlooked in cross-cutting. They are being followed up with the view of opening up an ore-shoot which shows on the surface. The Beaver has decided on sinking to at least 1500 ft., and has ordered a large hoist, of the Corliss type, capable of handling ore at a depth of between 1500 and 2000 ft. At 700 ft. the main orebody is well defined and productive, and similar results are looked for at the present low level of 800 ft. The 900-ft. level will be opened during the winter. The Penn Canadian has cut a new vein carrying 3 in. of 2000-oz. ore on the fifth level. The wall rock for two or three feet on each side of the vein carries leaf silver and will make good milling ore. Owing to the unfavorable condition of the mine, the Timiskaming will pass its usual dividend. The lower levels of the mine yield small patches of high-grade ore, but the returns in silver are small. Work on the North Dome of Porcupine, operated by the Timiskaming, will be discontinued owing to lack of funds. At the Foster a vein 2 to 3 in. of smallite has been found in an old stope, and some ore is being mined. The Casey-Cobalt has now 30 stamps in operation, with a daily capacity of 90 tons of ore. The battery is operated by electric power supplied from the Montreal river. The annual report of the Timiskaming & Hudson Bay shows a slight falling off in production. The output was 659,972 oz., and the cost of production 18c. per ounce. Dividends of \$186,264 were

paid. The mill treated 22,437 tons of ore during the year. The Coniagas declared an additional dividend bonus of 3%, making 14% in all, bringing the total dividend payments up to \$5,920,000 or nearly \$2,000,000 more than the capital. The Keeley mine of South Lorrain, which has made some good discoveries in the Keewatin of the upper levels, and has decided on deep-level explorations in the diabase, has been compelled to suspend operations until spring owing to inability to obtain electric power. It will be supplied next year from a new plant to be erected by the Northern Ontario Power Company.

The Porcupine Crown, formerly the McEnaney, is showing up well. Development work has proved the ore-shoot on the 300-ft. level to be larger than on the upper levels. The vein is proved up in quartz to a depth of 70 ft., where it assays \$60 per ton. In sinking a winze below the 400-ft. level the vein has been found to average \$80 per ton for 60 ft. down. The mill is crushing 80 tons per day. The Rea, operated by the Mines Leasing & Development Co., has since June 20 produced \$4500 with a 5-stamp mill running on low-grade ore. The September statement of the McIntyre shows that during the month the mill treated 2786 tons of ore, producing \$28,015. Operating expenses, which included the cost of an aerial tramway, were \$28,127. Alex. H. Smith has been put in charge of the Teck-Hughes at Kirkland lake, the position having been resigned by John Reddington owing to other engagements. At the Hollinger Reserve a winze is being sunk on the main vein below the 200-ft. level. The mine is being worked on option by the Kerr Lake of Cobalt. The Lucky Cross, in the Swastika district, has been reopened by a new force in charge of C. F. S. Anderson, late of the Buffalo. A month's test will be made to determine the best method of cyaniding.

KALGOORLIE, WESTERN AUSTRALIA

SONS OF GWALLA.—NEW CONSTRUCTION.

The Sons of Gwalla plant is being overhauled and brought up to date at a cost of \$150,000 by A. Wauchope, who succeeded John McDermott in December last. The framework, guides, and all woodwork of the mill are being renewed, and new mortar-boxes installed where necessary. The Wilfley tables have been scrapped, and three new 18 by 4½-ft. tube-mills, together with additional vacuum-filters, with all accessories, are being erected. A new Kynoch 660-hp. gas-engine is being added to supplement the two Crossley 400-hp. and 167-hp. engines, and all will be driven by Commonwealth generators consuming firewood of 3-ft. lengths and effect a saving over charcoal generators of \$1200 per month. Cement floors and drains are being laid down to prevent any losses of gold solution. The whole of the product will be slimed in future, and the old residue dump will be reground and treated. Changes are also to be made underground, as the ore-shoot has pitched so far south that trampling of 2000 to 2500 ft. has to be done at the lower levels. Larger passes and bins are to be made and horses used underground at intermediate levels, and so do away with hand haulage. Up to date the mine has produced 1,952,424 tons, yielding \$19,151,200 and paid \$4,771,800 in dividends. The ore in sight is estimated at 560,000 tons worth \$7.50 per ton, or 3½ years' supply for the mill. The main shaft is down 2800 ft. on the incline, and is still being sunk. There are 19 levels, the deepest being at an incline depth of 2700 ft. The ore-shoot appears to be coming back north toward the shaft, as at No. 19 level, the lode, at 300 ft. south, is worth \$10 over a width of 97 in., while at higher levels it was much farther south. In fact, at No. 14 level, the shoot has pitched so far south that shaft-sinking was suspended for three years, from April 1905 to February 1908. Shortly after taking charge in August 1906, Mr. McDermott, finding that the ore-shoot below No. 8 level was entirely south of the shaft, staked eight claims, comprising 192 acres, south of the shaft, and abandoned a similar area to the north. Since then practically the whole of the ore from the mine has come from this new ground, and this amounts to 1,286,560 tons, producing \$10,173,900, from which \$2,335,900 has been paid in dividends. This

is nearly twice the tonnage, and considerably more gold, and practically the same dividends that came out of the Company's holdings before Mr. McDermott's advent. Yet the ground lay open for years for anyone to take up. None of Mr. McDermott's predecessors made a move in this direction.

DENVER, COLORADO

STRIKE IN COAL MINES UNSETTLED.—STAG CAÑON DISASTER.—THE MOFFAT TUNNEL.—GOLD-DREDGING NEAR TIN CUP.

The strike in the coalfields of southern Colorado has rapidly grown into a state of civil warfare, which the local authorities appear to be utterly unable to suppress. In spite of the assertions of Frank J. Hayes, of the United Mine Workers, that the strike would be conducted along orderly and peaceful lines, there has been a steadily increasing amount of disorder and violence on the part of the striking miners. Serious conflicts between strikers and mine guards have been occurring daily, and several pitched battles have recently taken place. The lawless intent of the strike agitators has been apparent from the fact that nearly all of the strikers have been armed with high-power rifles, and it was recently reported that a machine-gun was shipped to the strike colony at Walsenburg. Ludlow has been the scene of constant rioting and violence ever since the strike began. Within the past two weeks armed bands of miners have made concerted attacks upon the camps of Primero, Sopris, Hastings, Aguilar, and Walsenburg. The Governor has concluded his trip of personal investigation through the strike districts, but he seemed at first in a state of indecision regarding the advisability of calling out the militia, although it has been apparent for some weeks that the sheriff was absolutely unable to preserve order or to prevent rioting and bloodshed. A number of strikers have been arrested, but there have been no convictions, and no serious attempts have been made to disarm the rioters who are terrorizing the coal camps. The Governor still seems to think that it may be possible to effect an agreement between the strikers and operators, but the latter maintain that their employees have no grievances and that they will not treat with those who have intimidated and driven out hundreds of perfectly contented miners who desired to continue at work in the mines. He has had several long conferences with the operators and the officers of the United Mine Workers in Denver in an attempt to adjust their differences, but the officers of the coal companies refuse to treat with the union, so there seems to be no hope for a settlement of the strike along those lines. The most recent press despatches state that the Governor has ordered two companies of the state militia to be sent to the strike districts for the purpose of disarming both the strikers and the mine guards and to preserve order throughout the coal camps, and that the importation of strikebreakers will be stopped. It is quite evident to all the people of the state that martial law should be declared and that the disarmament should proceed at once in order to put a stop to the continued state of armed lawlessness and violence.

The most appalling mine disaster in recent years occurred on October 22 at Dawson, New Mexico, in Mine No. 2 of the Stag Cañon Coal Co. A terrific explosion, supposed to be from some accumulation of gas, completely wrecked the mine, caused the blocking of every entrance, and entombed nearly 300 miners. In spite of the heroic work of the mine employees and officers, assisted by the crews of two mine-rescue cars, the death list will number 263 men, including the superintendent of Mine No. 2 and two helmet-men. Only 23 men are reported to have been saved. The exact cause of the disaster is unknown. The mine was considered to be one of the model coal mines of the United States, and was thought to be absolutely safe. The property is owned by the Phelps-Dodge interests, and is one of the largest coal mines in the country.

The contract between the Denver & Salt Lake Railroad Co. and the city of Denver, regarding the construction of the Moffat tunnel, has been signed by Newman Erb, president of the railroad company. A special city election will probably be called about January 15 to vote upon

the question of issuing bonds for the building of the tunnel by the city. Since the citizens of Denver have previously expressed their approval of this measure, there is little doubt but that the bond issue will be authorized. The tunnel commission has had examinations made of the proposed tunnel sites, and the board of engineers has made careful surveys and estimates, supplemented by a geological report by R. D. George, state geologist. The board of engineers is composed of D. W. Brunton, John W. Finch, and J. V. Davies. Mr. Davies is a member of the firm of Jacobson & Davies, of New York, which built the Hudson River tunnel of the Pennsylvania railroad. The members of the board will proceed immediately to make a thorough investigation of the proposed tunnel site on James peak, and will submit detailed estimates of the cost of the construction of the tunnel about November 15.

It is reported that dredging operations are to be begun upon the gold gravel deposits near Tin Cup in Chaffee county. These old placers were among the first gold producers in Colorado, and were profitably operated by hydraulicking for many years in the early days, but were finally abandoned on account of the lack of fill and dump room necessary for their operation by means of giants and sluices. The Tin Cup Gold Dredging Co. has recently secured several hundred acres of gold-bearing gravel, comprising a large number of the old placer claims. The ground has been thoroughly tested, with satisfactory results. The Company has completed an electric power-plant at St. Elmo, and has recently launched a modern gold-dredge.

BOSTON

YUBA CONSOLIDATED GOLD FIELDS.—THE STEPHEN R. DOW CASE.—ADVANCE IN BUTTE-BALLAKLAVA SHARES.—NEW ALASKA PROPERTY OF THE UNITED STATES SMELTING, REFINING & MINING COMPANY.

One of the most successful mining enterprises with headquarters in Boston is one about which the public is almost entirely ignorant. This is the Yuba Consolidated Gold Fields, operating in California. About 65% of the stock is or was held by the Robert D. Evans estate, of Beverly, Massachusetts, and other large stockholders,

ONE OF THE YUBA DREDGES.

including John Hays Hammond, A. Chester Beatty, W. P. Hammon, and the Albert F. Holden estate. There are probably not over a dozen stockholders in all, and reports are made to them in the most secretive manner. For the year ended February 28, 1913, the Company handled over 14,000,000 yd. of gold-dredging ground at a cost of \$760,365, making a net profit of \$1,640,000, or over 200%. Some of the dredges of this Company are said to hold records for low costs. Last year the average was 5.34c. per yard. This is regarded as one of the most successful enterprises with which Boston capital has ever been identified. The Company's gold-bearing ground is, of course, limited, but it still has a large liquidating value.

The argument on appeal of the case of Stephen R. Dow, who last February was convicted and sentenced to a prison term of not less than eight or not more than 12 years, will not be heard at the current session of the Massachusetts Supreme Court, but will probably come up

in January. Dow is at liberty on \$25,000 bail. He was convicted on 24 counts based upon the fraudulent appropriation and conversion to his own use of \$251,764 belonging to the Algomah, Franklin, North Lake, and Indiana companies of the Lake district. It was claimed that Dow had borrowed \$1,000,000 from these companies and had paid back \$800,000. He started business with a seat on the Boston Stock Exchange in 1905.

The market action of Butte-Ballaklava, which in a recent movement has advanced from under \$2 to nearly \$6 per share, has been due to the belief that the Company's litigation with Anaconda will be settled out of court. Mr. Ryan, president of Amalgamated, denies this report, but the Butte-Ballaklava interests have sanctioned it. It was stated that a compromise would be effected and the suit withdrawn through Anaconda taking over Butte-Ballaklava on a one-to-five share basis, involving the issue of 50,000 Anaconda shares for the 250,000 Butte-Ballaklava shares now outstanding.

The most important announcement recently in a market way from Boston has been that of the acquisition by the United States Smelting, Refining & Mining Co. of several low-grade gold properties in the Juneau, Alaska, district, where the Company will carry on another mammoth mining enterprise similar to that of the Alaska Gold Mines Co. The smelting company has acquired ample water rights on Lemon creek at Juneau and has taken an option on the Ebner mine which runs until March 1915. The United States Smelting interests are perhaps the most active of all the large corporations with exploration departments in their search for new mining properties, but they have not succeeded in getting more than one or two a year on an average, although they take up each year from 700 to 900 properties for consideration. The United States Smelting, and Hayden, Stone & Co. interests are very close together in many ways, the late Albert F. Holden having been prominently identified with both groups. Both interests believe the Juneau district will become the greatest gold-producing territory in the United States.

Stock market interests here believe the days of the Lake Superior copper strike are numbered. The Western Federation of Miners has been defeated again, it appears, in its effort to get a new footing in this mining district. The Calumet & Hecla and other companies are willing to make concessions, but will not recognize the union.

NEW YORK

U. S. S. R. & M. TAKES HOLD OF THE EBNERS.—ELY CENTRAL JOINS COPPERMINES.—TULAROSA.—TENNESSEE COPPER.—MEXICAN COMPANIES SUSPEND DIVIDENDS.

Much interest has been evoked by the possible advent of the United States Smelting, Refining & Mining Co. into the Juneau district, which has been the scene of such profitable activity by the Bradley interests for many years, and where the Jackling, Aldrich, McNeill, and Hayden-Stone interests are now directing attention through their rapid development of a large low-grade producer in the Alaska Gold Mines, which has taken over the old Alaska Perseverance or the Alaska Gastineau. Adjoining this is the Alaska Juneau, of which F. W. Bradley and associates have secured the control and which they are developing into a large low-grade mine, as announced in earlier issues. Just beyond this is the Alaska Ebner, which has been marking time, like the others, its development being especially hampered by the internal dissensions in the owning company. So little development work had been done that the value of the property was problematical. The United States company has taken an option, extending till March 1915, and will drive a long cross-cut to develop ore in depth, as has been done at the other two properties. The necessary water-power has been secured through additional options on water rights on Lemon creek and elsewhere. The cross-cut should reach the vein early next year, leaving ample time within the life of the option for the necessary development work to prove tonnage. With three such strong groups at work, the mainland opposite Douglas Island has blossomed rapidly into

importance as a gold-mining district of great promise.

Absorption of the Ely Central Copper Co. by the Consolidated Coppermines puts the latter into an even stronger position, and if any more big orebodies are developed in the Ely district they can scarcely escape being in the Consolidated Coppermines ground. It is to be hoped the Ely Central will not prove a 'hoodoo,' for its unhappy memory of the time when it served merely as an appendage of the bucket-shop run by 'Geo. Graham Rice' and B. H. Scheffel & Co. is scarcely likely to endear it to anyone. The property consists of about 480 acres adjoining the Copper Flat pit of the Nevada Consolidated. Three shafts have been sunk without developing any large orebodies, but the ground has not been thoroughly drilled. The stock is to be exchanged on the basis of 20 shares of Ely Central for 1 share of Consolidated Coppermines. Doubtless the shareholders will consider themselves fortunate to get out of a swindle and into a good company on any terms whatever.

Speaking of copper companies, some of the interests on the New York curb market are vigorously boosting the Tularosa Copper Co., which owns a property of a good deal of promise in Otero county, New Mexico. The ore deposits of this property were described by S. H. Ball in the *Mining and Scientific Press* of July 26, last. They consist of a stockwork of lenses in diorite, stringers of ore extending into the sandstone from the diorite, bedded ores in sandstone, and detrital deposits. The statement is made in brokers' circulars that 800,000 tons of 2½% copper ore has been developed. There is a 150-ton mill on the property, and the venture seems to be of much promise, though it is perhaps a question whether F. P. Kern, the president, and his associates will be able to make it blossom out very rapidly, as they are reported not to have the almost unlimited financial resources which have contributed to the development of some of the large new properties.

The Homestake Mines Finance Co., which has chosen a good name in the hope of developing a good mine, is at work proving the ground of the Commonwealth Gold Mines, Ltd., and the Sherill Porcupine Gold Mines, Ltd., which it controls. Each of these companies owns 200 acres of land in Tisdale township, Ontario, and is hoping to develop valuable deposits. The Homestake also owns 255,000 shares of the Foley-O'Brien. The Company is capitalized at \$1,000,000, and is controlled by Buffalo people, W. H. Finch being president, Frank L. Bapst vice-president, S. J. Dark treasurer, and as directors F. V. E. Bardol, C. W. Williams, F. Irwin, and C. L. Sherrill, all of Buffalo, New York, and Alexander Fasken. E. V. R. Mac-Millan of Toronto is secretary.

The Tennessee Copper Co. is said to be making excellent profits from the sales of acid, which continue to increase, and is turning out copper at the rate of 1,500,000 lb. per month. Nevertheless, its shares display a good deal of weakness, and it has been suggested that the activity of its president in Gold Hill, with which Walter George Newman is associated, is scarcely to the advantage of Tennessee Copper. The Greene-Canaan has resumed dividend payments with the declaration 1%, payable December 1, after a period of interruption due to the disturbed condition of affairs at its mine and smelter throughout the spring and summer. Even yet the properties in Mexico are operating at little more than two-thirds capacity, but the prospect of better conditions soon is judged to justify resumption of dividends. The Mexican Lead Co. and the Montezuma Lead Co., controlled by the Compania Metalurgica Mexicana, owned by the Towne & Peabody interests, will pass their November dividends, having paid none for over a year, the disturbed conditions at Monterey and at Chihuahua having prevented work. All the properties of the Mines Company of America are now shut down except the La Dura, which still continues. This Company has done remarkably well, having made a net profit of \$360,000 during the first half of this year, and not until recently has work been seriously interfered with. If conditions in Mexico get much worse, something must happen, and whatever it is, it is likely to be for the better.

General Mining News

ALASKA

Alaskan coalfields continue to be undeveloped, according to the U. S. Geological Survey. The only coal being mined is some lignite for local use at Cook Inlet, on Seward peninsula, and at several other localities. The total production in 1912 did not exceed 100 or 200 tons. One oil company continued operations in the Katalla petroleum field in 1912, as in 1911. One of the two producing wells is said to have been sunk to a depth of about 800 ft. The oil is procured by pumping and is refined in a small plant near Katalla, and the gasoline finds a ready sale in the coastal settlements of this part of Alaska. There are

new hoist has been installed at the Donkey zinc mine at Ingot. A large tonnage of ore has been opened and shipments have been made to Utah smelters. The Balaklala Copper Co. is employing 41 men at the mine and smelter. The gas receiver for the Hall process is expected in a few days. It is to be 22 by 45 ft., of steel. The Company has been shipping 55 tons of 3.25% copper and \$2.50 in silver ore daily to the Mammoth smelter at Kennett. Precipitating vats are being built at the Balaklala mine to save the copper in the water.

TUOLUMNE COUNTY

(Special Correspondence.)—The mines depending alone on water for power will be forced to suspend operations on October 31 until rains replenish the supply, which is almost exhausted. Work in the shaft at the Wheal Rough

CYANIDE MILL AT TREADWELL, ALASKA.

several other oil companies which control property in this field, but these seem to have done little in the way of development during 1912.

JUNEAU

September returns from the Alaska Treadwell stamp-mills are as follows:

Ore crushed, tons	78,113
Gold by amalgamation	\$112,955
Gold by cyaniding 1509 tons of concentrate.....	115,235
Total realizable value	225,908
Net profit	123,310
Development, feet	218
Stock of broken ore, decrease, tons.....	8,821

The Alaska Mexican company reports that 17,364 tons was crushed, yielding a total of \$35,709 by amalgamation and the treatment of 394 tons of concentrate. The net profit was \$7625. Development covered 189 ft., and the stock of broken ore decreased 6630 tons.

ARIZONA

GILA COUNTY

All steel is now in place for the Inspiration concentrator warehouse and machine-shop, and riveting has been started. Work will shortly be commenced on the steel trestle reaching over the concentrator ore-bins. Within a few days steel will arrive for the main east and west shaft head-frames. This will be a twin frame fastened together for the two shafts, the main west frame being 165 ft. high, while the main east will be 185 ft. high.

CALIFORNIA

NEVADA COUNTY

A 10-stamp mill is being erected for the Golden Center of Grass Valley Mining Co., and the superintendent, Charles Brockington, hopes to have it working in December.

SHASTA COUNTY

It is reported that the Bully Hill Smelting & Mining Co. will resume work at its property at Delamar, shortly. A

mine, near Soulsbyville, was discontinued this week after sinking 200 ft., and cross-cutting to the vein, a distance estimated at about 15 ft., was begun. A shipment of rich ore from the Sonnet mine, near Columbia, to the Selby smelter was made this week. The parties to the suit involving the O'Donnell mine, near Jamestown, have agreed upon a settlement of the controversy. The action was begun about five years ago. The Pot Luck mine, near Phoenix Lake, is to be equipped with a 5-stamp mill. Other buildings besides the one for the mill will also be erected. D. T. and E. W. Morris, who are driving an adit to cut the ancient river channel in Table mountain, expect to reach the objective point within a few weeks. The adit is in 125 ft. The Gold Ship mine, near Groveland, at which development work has been carried on for a number of years, has begun yielding gold, the roller-mill, recently installed, being in operation since October 20. A gravel deposit 80 ft. wide and several feet thick was recently opened, and the gravel being extracted, it is understood, is giving profitable and satisfactory returns. William J. Graham has been manager of the property since the beginning of development work.

Sonora, October 25.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Shipments will be started next week from the French Flag mine in Gilson gulch to the Combination mill. It is estimated that there is 11,000 tons of material available, worth \$7 per ton in gold and silver. C. S. Ripley is manager. A shoot of galena, 4 ft. wide, has been cut in the White vein, 2700 ft. from the portal of the Commodore adit. Shipments assay \$25 per ton in silver and lead. F. Koontz is manager. The Newhouse mill has been closed for repairs, and it is understood that with the resumption of ore treatment a new manager will be in charge. The Little Mattie is shipping on an average of four carloads of smelting ore each week that is worth \$2400 per car. The 100-ton con-

centrating plant is running on three 8-hour shifts and is making heavy shipments. W. S. Leebrick is manager. Work will be started in a few days in the advance of the east Bellman drift that is intended to connect with the lateral drift west from the Newhouse adit. D. A. Barry is in charge. The Idaho-Bride M. & M. Co. is producing from 1000 to 1100 tons of mill ore each month, valued at \$4 per ton. The product is consigned to the Newton and Jackson mills for treatment. E. D. Payne is manager. The Captain Jack mine, on Columbia mountain, has entered the list of shippers. John R. Richards is manager.

Idaho Springs, October 30.

EAGLE COUNTY

The Brush Creek district is said to be active, yet little ore is being shipped, 13 tons of 52-oz. silver ore daily going from the Lady Belle. The hanging wall of this vein is sandstone and the foot-wall is schist. The main adit is in 240 ft., and an incline is being sunk northwest at 150 ft. from the mouth. Twenty-eight men and four teams are employed. Above this property is the Dakotas, where ore is being mined from a 'sheet' of porphyry in the sandstone. S. A. Nicholson and other Leadville people are prospecting a claim east of the Lady Belle, but water is hindering work. W. E. Brown and associates have not opened any ore to date.

GUNNISON COUNTY

The Tin Cup Gold Mining & Dredging Co., capitalized at \$300,000, has begun work in the Bertha gulch near Tin Cup. The cost of getting the machinery to the site, together with the cost of installing it and bringing electric power from St. Elmo has been close to \$200,000, but the Company fully expects to make that amount in two months. There have been between fifty and sixty men employed here since early in June.

LAKE COUNTY (LEADVILLE)

On account of recent snowfalls, prospecting in this district is at an end for the season. The *Carbonate Chronicle* considers that the work of the summer has been of great promise, especially in Big Evans, Iowa, California, Half Moon and Lackawanna gulches, where are the makings of producing mines. The Silver Bow Mining Co., operating the Big Four on Breece hill, is shipping gold-silver-lead ore to the Arkansas Valley plant. Lessees at the Lida shaft, Laplander, Little Giant, Baby shaft, Jolly, Chippewa, Bobbie Burns, and Iron Hat are doing the usual development and mining of ore.

TELLER COUNTY (CRIPPLE CREEK)

The following dividends have been paid by five important companies operating at Cripple Creek during the 10 months of the current year: El Paso, \$61,250; Elkton, \$150,000; Golden Cycle, \$315,000; Portland, \$240,000; and Vindicator, \$104,740. From January 1 to September 30 the Mary McKinney Mining Co. had a revenue of \$276,922, and a net profit of \$95,722. Four dividends, totaling \$104,740 were paid, and the cash balance was \$105,671 at the end of September. The main shaft is being sunk from 900 to 1000 ft. depth.

The station pump which was installed at the property of the El Oro Mining & Milling Co. is making good headway toward dewatering the shaft, which work will continue until the 500-ft. level has been recovered. A cross-cut will be started from the 500-ft. level toward the Carbonate Queen claim.

A good grade of milling ore is being mined by the lessees of the Vindicator Gold Mining Co. from a shoot which has been opened on the Vindicator vein, north of the main shaft at a depth of about 1000 ft. The ore is being hoisted through the Hull City shaft. The Vindicator company, which is operating the main shaft, is making a normal production and plans are under way for deepening the main shaft to 1600 ft. The Home Run mine, on the southern slope of Squaw mountain, is being worked under lease by Victor interests. This property adjoins the Santa Rita, which is also reported as about to resume operations.

THE SAN JUAN

Results from the Tomboy Gold Mines, Ltd., at Telluride,

during the year ended June 30, 1913, are as follows:

Ore reserves:

Argentine claims, tons	264,000
Montana claims, tons	162,000
Ore treated, tons	129,618
Bullion receipts	\$1,040,357
Profit	471,345
Carried forward to current year	193,000

Work was to have been resumed in the Argentine group below the 2100-ft. level, but has been postponed and concentrated on the Montana group. Improvements in the mill have resulted satisfactorily, and the aerial tramway is saving from \$4000 to \$4500 per month. This is owned by an American company, the Tomboy Tramway & Tunnel Co., owned by the parent company.

IDAHO

SHOSHONE COUNTY

About 1500 tons of silver-lead ore monthly is being shipped from the Tamarack & Custer mine on Nine-Mile creek, to the Rex mill. Stopping is under way at the 500 and 750-ft. levels, where the ore is from 3 to 30 ft. wide. Extensive development is to be done at the Monitor mine, in the east Coeur d'Alene district, near the Montana boundary line. The properties recently merged include the Monitor, Richmond, St. Lawrence, Copper Age, Edison, and Waumpum claims. The first named is opened to 700 ft. depth, and has produced copper ore worth \$150,000. High-grade ore has been shipped from the Richmond and St. Lawrence. It is proposed to drive an adit 8000 ft. in length and 3000 ft. of cross-cuts, giving a vertical depth of 1500 to 2000 ft. in the various claims. A hydro-electric power-plant of 200 hp. is to be constructed at Adair on the Chicago, Milwaukee & St. Paul railroad. The mines are at an altitude of 6000 ft. above sea-level. On November 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 194 of \$81,750. This makes the total amount of dividends paid \$14,647,500.

MICHIGAN

HOUGHTON COUNTY

There has been a steady increase in 'rock' shipments during the past week, and large numbers of men are being engaged at the copper mines. Calumet & Hecla has shipped 5640 tons per day; Copper Range, 1200 tons; Quincy, 1500 tons; Isle Royale, 300 tons; Osceola, 1600 tons; Centennial, 220 tons; Allouez, 160 tons; and Superior, 320 tons. The Ahmeek, Wolverine, Mohawk, and Tamarack have not sent out any rock yet, but hope to during the present week. At La Salle a new pump has been installed underground, while at the Lake, Indiana, South Lake, and Franklin there is little being done.

The Franklin Mining Co. has recently issued its annual report. This Company was organized in 1857 and was reincorporated in 1887; its capitalization is now \$2,500,000 in shares of \$25 each. The Company owns about 1700 acres, its mineral rights covering 320 acres. Half of this is the old Franklin mine, which is surrounded on three sides by the Quincy, and which is nearly worked out. In the Franklin Jr., mining is in progress on the Pewabic amygdaloid and also in the Allouez conglomerate. The report for the year ended Dec. 31, 1912, only covers 10 months' work, as the mine was idle during January and nearly all of July. The output for the year was 184,057 tons of ore hoisted. Of this 4.1%, or 7,585 tons, was sorted out and the remainder milled, yielding 1,710,651 lb. refined copper, or 9.8 lb. per ton. The mill has a capacity of 1200 tons per day, but due to the shortage of labor the best average attained during the year was 800 tons per day. During the year 5134 ft. of development work was done, with most encouraging results, as an area of better grade ore was developed north of the shaft in the upper levels and on both sides of the shaft in the two bottom depths. The 1200 ft. of driving on the 32nd and 33rd levels has developed ore of better grade, showing not only an increase of copper content, but also more uniform distribution of the copper. The cost of driving was \$5.79 per foot, and cross-cutting 5.57. Raising cost \$9.30 per foot and sinking \$11.58 per foot. The stopping cost is

given as \$6.62 per fathom. The treasurer's statement shows that \$1,710,650 lb. of copper realized \$287,286, and the surplus at December 31, 1912, was \$41,839.

MISSOURI

JASPER COUNTY

Work has been started on the Martin claim of the General Lead & Zinc Co., near Thomas station. The shaft has been cleaned and continued to a depth of 80 ft., where a good grade of ore is reported to be found.

The Lee Hall mine has temporarily ceased producing, and development work is being actively conducted. The property is equipped with a concentrating plant and has been a good producer during the past seven years.

Severe weather has been the cause of curtailing the prospecting work in different parts of the Joplin district, it being almost impossible to operate a churn-drill in stormy weather. A number of the small hand-jig plants have also been forced to suspend operations, as is the case every winter.

MONTANA

SILVERBOW COUNTY

The report of John D. Pope, general manager for the North Butte Mining Co., covers the quarter ended September 30, 1913. Development totaled 4306 ft., and the ore reserves have been maintained. The Granite Mountain shaft is now 20 ft. below the 2600-ft. level. A raise between the 2000 and 1800-ft. levels has proved the Adirondack vein to be continuous, and on the former level the shoot is 300 ft. long, 30 in. wide, assaying 8.5% copper, and 9 oz. silver per ton. Driving east and west on the 2400-ft. level has opened 90 ft. of ore 3.5 ft. wide, worth 3.5% copper and 2.5 oz. silver, and 185 ft., 13 ft. wide containing 4.5% copper and 3 oz. silver, respectively. Work between the 2000 and 1800-ft. levels on the Edith May vein has developed an additional total of 15,000 tons of 6.5% copper ore. A small shoot of 9% ore was opened on the 1600-ft. level on the Jessie vein, also on the South Croesus vein a cross-cut passed through ore. Work on the Snowball vein on the 1600 and 1800-ft. levels indicates that the ore does not rise above the latter point. Results at 2200 and 2400 ft. on this vein were good, although in the east drift the vein was badly faulted for a time, but is now 9 ft. wide of 4.5% copper ore.

The Butte & Superior mill treated an average of 1149 tons of ore daily during the first 10 days of October, with 90.28% recovery, yielding 3,993,000 lb. of zinc. Stripping operations at the Bullwhacker mine have uncovered a shoot of sulphide 12 by 30 ft., with ore still exposed at each end and averaging 12% copper. The body of ore is in a formation of copper-bearing rock that assays 4% over 200 ft. At the mill, a decantation process is being tried in place of filtration, and results so far are satisfactory. It is intended increasing the capacity of the plant to 500 tons per day.

NEVADA

The state inspector of mines, Edward Ryan, after a tour of the state's mining districts, reports that he is highly optimistic regarding the future of the industry in Nevada, there being almost a total absence of 'wild-cat' business, and considerable genuine prospecting and development.

CHURCHILL COUNTY

Eastern capitalists have acquired 24 claims in the Dixie district, between Marvel and Boyers, from John O'Connell for \$125,000. The property contains wide veins averaging 2% copper, with some gold and silver.

The Nevada Hills Mining Co. reports as follows for September:

	Value.	Per ton.
Ore milled (4307 tons)	\$50,392	\$11.70
Metals withdrawn from absorption.....	3,010	0.70
Total	\$53,402	\$12.40
Loss in tailing	5,463	1.27
Recovery	\$47,939	\$11.13
Expenses	30,376	7.05
Net returns	\$17,563	\$4.08

Cash on hand and in banks	\$92,911
Supplies on hand	42,830
Concentrate in transit	7,880
Metals in solution, etc.....	20,244

Total resources\$163,865
There are no liabilities.

ELKO COUNTY

Work is reported to be satisfactorily progressing in the vicinity of Bullion. A traction engine is to be put into service for the transport of ore from Bullion to a shipping point a few miles south of Elko on the Western Pacific railway. Ore is at present being shipped out by way of Eureka and the Palisade road.

ESMERALDA COUNTY

With the checks for dividend No. 19, at the rate of 40c. per share, the Goldfield Consolidated Mines Co. reports as follows for the third quarter of the current year:

Ore treated, tons	89,611
Gold recovered	\$1,085,189
Costs	565,650
Net realization	519,539

The output of the Goldfield Consolidated Mining Co. for the month of September was \$21,000 less than that of the preceding month. This property, which was one of the largest gold-producing properties, has distributed dividends to the total of \$25,000,000 during the past few years. The Company is now producing ore from the 1400-ft. level of the Grizzly claim. There still remains a large area of ground to be exploited.

HUMBOLDT COUNTY

At National, the Buckskin National mine is southeast of the National and in the 160-ft. incline shaft a narrow vein has been opened assaying thousands of dollars per ton in gold. At 600 ft. in the National, good ore is being opened over 3½ ft. width. The mill is treating about 30 tons per day. A bond has been secured on the old Montezuma mine, near the middle of the county by Mr. Campbell. This mine has yielded rich silver-lead ore. For the transport of ore from Rochester and supplies to that place, a 4.5 mile narrow-gage railway is now in successful operation, having been constructed for A. A. Codd, of the Rochester Hills Mining Co. It extends from Nenzel, formerly known as Oreana, on the Southern Pacific line, to the mouth of Limerick cañon, one of the outlets of the Rochester district. The equipment consists of an oil-burning locomotive and one gasoline locomotive, two flat cars and 10 steel side-dumping ore cars. The Company's main shaft is down 250-ft., and 50 tons of \$25 ore is being shipped per day. The total to date is approximately 6000 tons, worth \$150,000. It is probable that a 10c. per share dividend will be paid at the end of the year. The line is proving a boon to mining in the Rochester district. Although originally planned solely for the transport of ore, the line is now being used as a common carrier, and besides moving the ore from Packard and Rochester, it is also carrying in supplies to these towns and to those which lie on the east slope of the Humboldt range.

Exploration and development work is being done on the claims of the Excelsior Copper Mountain Co. The ore is reported as highly desirable, as it carries a good per cent of magnetite and has valuable fluxing qualities. The principal work is being done through a shaft which has reached a depth of 700 ft., and it is expected that by the first of next April the Company will have sufficient ore hocked out to determine the future policy of the Company.

LANDER COUNTY

A report has been published by Paul Valtinke, of Salt Lake City, on the Highland National Mining Co.'s property in the Mt. Tobin district, 40 miles southeast of Battle Mountain. He states that the vein has been traced for 4000 ft., and has a great width, and the ores are silver bearing. It is probable that the sulphide zone will be reached at a depth of 200 ft., judging from neighboring properties. The Cholona Copper Co., consisting of Utah and Idaho people, is sinking a shaft to 300 ft., and rich

ore is being obtained from a winze. The Nevada Packard Mines Co. has shipped 16 cars of ore averaging \$55 per ton since May.

LYON COUNTY

Results at the Nevada-Douglas mines are very satisfactory, especially the Casting Copper section, where 5 to 20% copper ore is being opened. Plans for the leaching plant have been submitted by W. E. Greenawalt, the Company's metallurgist, and the engineering department is in the field working on the details for the site. The site selected is at the mine, and about 1200-ft. from the Ludwig shaft, and about the same distance from the lower terminal of the Douglas Hill tramway. This location will do away with, or greatly reduce, the freight charges on the crude ore, and will eliminate the building of a power-line. It will also eliminate the installation of a pumping system, as the water from the Ludwig will be more than ample to supply the mill. As at present planned, the storage bins are so situated that they may be reached by simply extending for 800-ft. the N. C. B. siding at the Ludwig. The following has been extracted from a report recently made by the general superintendent of the Nevada-Douglas company: "While I have always been firmly of the opinion that the ore continued down, it is very gratifying to encounter and to prove it at depth and with so little development as has been required. It is now an assured fact that the ore found in the Ogden cross-cut in the No. 2 tunnel, at a depth of 150 ft. vertically below the main Douglas Hill level, is a continuation of this body, and a raise on the ore will be started from the No. 2 tunnel to connect the two. Cross-cuts will be run to ascertain the width of this body, which has been developed for 85 ft., and which has a vertical depth of at least 150 ft. As no development work has been done below the No. 2 level, I cannot at present state how much deeper this ore will go, but every indication points to permanency. This development work will increase the ore reserves very materially, as I am at the present time shipping only the ore extracted in the progress of development. From all of the samples taken, which have been running from 4 to 22% copper, I think it can be stated to have an average value for the entire body of from 6 to 8% copper."

NYE COUNTY

Development work on the 600-ft. level of the West End property has opened 9 ft. of a good grade of mill ore on the hanging wall side of the vein. The winze is 100 ft. below the 600-ft. level and has proved the extension of ore in depth for this distance. The ore is of a poor grade on the foot-wall side, but on the hanging-wall side some exceedingly rich ore has been found. The extreme west drift on the 600-ft. level shows a full face of a good grade of mill ore, in which are found streaks of ruby silver. This is believed to be an extension of the rich ore-shoot opened some time ago in stope 501-C above the 500-ft. level. In the eastern workings two raises are now in ore from the east foot-wall drift under the vein on the 600-ft. level. A third raise has been commenced, which is expected to be in ore in a few days. The stope from the winze between the 500 and 600-ft. levels is opening up a good grade of ore. The vein at this point is heavily oxidized and shows native silver.

The Belmont vein has been opened to a depth of 1528 ft., where it is from 25 to 30 ft. wide and has been driven on in an easterly direction for a distance of about 300 ft. The vein here is heavily oxidized and shows evidence of leaching, indicating that a good percentage of the metal content has been carried to greater depth. On one of the upper levels this vein has been driven on for a length of 1000 ft. and has been found to be from 25 to 40 ft. wide. Shoots of exceedingly rich ore occur at intervals through the vein and continue to the lowest level, where a body of high-grade ore was followed in a winze from the 13th to the 14th level. The Shaft vein has now been proved from above the 1000-ft. level, where it unites with the Belmont vein, down to the 12th level.

STOREY COUNTY

The annual meeting of the Sierra Nevada Mining Co. was

held in San Francisco on October 26. The superintendent, C. E. Julihn, reported that all work had been concentrated toward the development of the east vein on the 2000, 2400, and 2500-ft. levels, where a total of 1874 ft. was covered. The vein on the first level was 4 to 7 ft. wide, of masses of talc and bunches of quartz of low value, and was opened 133 ft. On the 2500-ft. level the northeast drift followed the vein through several faults to a distance of 965 ft. from the southern boundary. At 320-ft. there was 4 ft. of \$6.50 quartz. From this point on, the vein has been from 2 to 9 ft. wide, \$13 being the highest assay. At present there is 6 ft. of ore with 2 ft. of \$2 quartz. In raising from 2500 to 2400 ft., silver content of the ore was contained in small stringers, this continuing for 62 ft., where two faults cut out the vein. About \$9000 was recovered from this work. Great hope is felt for the future development of the property.

WASHOE COUNTY

There is said to be considerable activity in the districts adjacent to Reno. At the Reno Peavine property a new hoist is being installed at the shaft, which is 247 ft. deep. A road is being constructed by the Copper Queen owners for hauling ore now on the dump. The Stoke-Pogis people are also preparing a road for hauling supplies. Prospecting and development is being done by Lynch, Zimmer, and Hagar at their respective claims in Horse gulch; by Rice and others near the Copper Queen; Gaston and Montrose are opening ore near the Nevada Central; also Pritchett and Smith are sinking on \$5 to \$16 gold ore nearby; the Williams and Godfrey shaft is being sunk to 200 ft., and two cars of ore recently netted \$50 per ton; while a 5-ft. vein is being opened in the Twiu Metals claims.

WHITE PINE COUNTY

The new stack of the Steptoe smelter was being lined with an acid-resisting compound on October 20, when a gasoline torch caused an explosion, resulting in the death of two and injuries to four men. Quarterly statements have been received in the county assessor's office from the Vulcan Mining, Smelting & Refining Co., and the Hamilton Power & Mining Co. for the period ended September 30. The Vulcan company, whose property is situated in the Hunter district, shipped 223 tons yielding \$6591, with a net yield of \$387. The Hamilton company, at Hamilton, shipped 94 tons yielding \$8590, with a net yield of \$24.

At the rate of \$2.16 per \$100, the Nevada Consolidated Copper Co. will pay \$6125 in taxes on its operations during the third quarter of the year. These were as follows:

Ore milled, dry tons	813,511
Gross value of ore	\$2,477,305
Cost of mining	570,188
Transportation charges	215,072
Reduction and smelting costs	1,408,468
Net yield on which bullion tax is due	283,576

The output of ore from the Veteran mine has been materially decreased during the past few months, and unless new orebodies are found it is believed that this property will soon be forced to suspend operations, and the operating force transferred to the Ruth property. It was estimated some time ago that there was developed on the Ruth property over 13,000,000 tons of ore. This property is equipped with electric haulage to the Star Pointer shaft, which is in good condition and ready for use.

Two veins are being opened in the Shepherd claim in Heath cañon by Guy L. Gallagher, who has shipped 22 sacks of ore to Salt Lake City for testing purposes. The average value is estimated at \$60 per ton in gold.

The Consolidated Coppermines Co. will probably commence the actual work of construction of the new concentration plant and smelter next spring. It is estimated that 2,000,000 tons of commercial ore has been added to the reserves of the Company since last July. A good part of this new ore has been developed by means of churn-drills. The depth of the ore in the new open-pit on the Ora claim has not as yet been determined. It has been shown, however, to be 900 ft. long and 300 ft. wide, and is believed to contain several million tons of ore. The work of grading for the opening of a new pit to the east

of the Morris shaft continues. This ground when ready for mining will be worked by steam-shovels. The new pit will lead directly to the Morris workings, which will eventually necessitate the removal of the equipment at the Morris and Bunker Hill shafts. A part of the grading for the railroad to be used for stripping operations has been completed. A report has been circulated to the effect that the Coppermines company is contemplating the purchase of the Ely Central Co., in the Ely district.

UTAH

JUAB COUNTY

On October 25, the Iron Blossom company paid its fourth dividend this year, amounting to \$100,000. The surplus is now \$250,000. On the Salt Lake City Stock Exchange the shares were sold at \$1.12.

SUMMIT COUNTY

The deal between the Daly Mining Co. and the West Ontario Consolidated Mining Co. for the purchase of the latter's property, has fallen through for the time being. Since cutting ore at the end of last May in the American Flag, ore worth about \$24,000 has been shipped. Preliminary work for the electrification of the Snake Creek tunnel is nearly completed, and the necessary machinery will soon be ready for installation. Fred T. Williams is contractor for driving the tunnel, and expects to continue work during the winter. Ore shipments from five mines during the past week totaled 1023 tons.

TOOELE COUNTY

Work is to be started at the Dugway Silver Bell Co's property in the Dugway district on November 3. Eighteen inches of silver ore had already been opened, and trials between a leaching and a concentrating process seem to favor the latter. Rich concentrate would then be shipped to the smelters.

WASHINGTON COUNTY

According to J. B. Jenson, the Bull Valley district, 30 miles north of St. George, promises to develop into a large gold producer. The country contains a series of east and west mineralized dikes. Samples from the Bull Valley Gold Mining Co.'s property assay \$10 per ton.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—A meeting of the users of power in the Republic 'camp' was held recently, at which a resolution was adopted favoring the use of Diesel engines at a central power-plant, for the distribution of cheap power. A committee was appointed to inquire into the cost of such engines, and their installation.

Republic, October 24.

STEVENS COUNTY

(Special Correspondence.)—High-grade ore has been opened in the International mine in the Orient district. Two cars of ore from the Copper King, at Chewelah, returned \$12 per ton over freight and treatment at the Grand Forks smelter. No. 3 vein is 23 ft. wide. Eighty men are employed at the United Copper mine.

Chewelah, October 24.

CANADA

ONTARIO

During the third quarter of 1913 there were 10 fatal accidents at mines in the province, making a total of 26 for the year to date. About half of the last quarter's fatalities were caused by premature explosions. The Drummond fraction, purchased from the Drummond Mining Co. jointly by the Kerr Lake and Crown Reserve mining companies, is to be worked as a separate unit. Nearly eight acres is under Kerr Lake, which is now being drained, and work is to be started at the fraction at once. On No. 5 level of the Penn Canadian, about 3 in. of 2000-oz. ore has been opened in a new part of the mine. Owing to shortage of power, the Keeley mine, in South Lorrain, is to be shut down for the winter. Prospecting during the summer has been quite satisfactory.

The production of the Hudson Bay mines for the month

of September was slightly below normal, the production figures being as follows:

Tons crushed	1,776
Average assay head, ounces	23.9
Average assay tailing, ounces.....	3.1
Extraction, per cent	87.4
Month's production, ounces	42,643

The production for the month of August was over 70,000 oz., which is above what has been the average. The whole of the production is not obtained from the mill, a good part of it being obtained from high-grade and hand-picked ore.

The work of draining Kerr lake is making good progress. At the present time 3000 gal. of mud is being pumped per minute. This muddy sediment covers the lake bottom to a depth of from 10 to 40 ft. and as removed is being transported through a large pipe-line to Glroux lake. The sediment carries about 80% water and as a result it can be pumped, and hydraulic operations will not be necessary as was anticipated. At present but little water remains in the lake, and at the present rate of pumping it would be possible to complete the work of draining by the first of the year; however, it will be necessary to close down the plant soon, due to the winter weather. The lake bottom will be trenched and prospected next summer. Three of the veins which were discovered in the lake bottom some time ago have been opened on the 140-ft. level of the No. 7 shaft of the Kerr Lake Mining Co. The extension of the main east vein of the Flemming system will be worked in the near future.

In sinking a winze on the Crown mine below the 400-ft. level, 5 ft. of vein has been opened averaging \$50 per ton. The manager of the property expects to cut the 500-ft. station within the next two weeks. At the 300-ft. level the vein showed a continuous length of 600 ft. According to Mr. Cohen, the general manager, there is at present ore to the value of \$1,700,000 blocked out above the 400-ft. level, all of which has been developed from one shaft. A second shaft is being sunk to the south of the main working, which when completed will be 1000 ft. in depth. The diamond-drill exploration work in this part of the property has been most satisfactory and has proved the ore to a depth of 300 feet.

YUKON

During the third week in October, ice was flowing heavy on the river at Dawson, although no snow had fallen. The Yukon Gold Co. has dismantled two dredges. One at 62 Below on Bonanza will be moved during the winter to No. 12 Gold Run and rebuilt. The other will be moved from the Anderson concession to No. 41 on Hunker creek, a distance of five miles. The Company had about 40,000 cords of wood delivered in the summer for thawing on Hunker and Bonanza creeks, while more will be hauled this winter. Frank Neill hauled 17,000 cords to Dawson, and 15,000 cords were brought down the Klondyke for the Yukon Gold Co. by N. A. T. and T. Labbe and Chisholm.

CHILE

(Special Correspondence.)—The plant of the Sociedad Beneficiadora de Condoriaco, Ltd., has been sold to Mark R. Lamb, who, with D. C. Woodward, T. L. Slaughter, and F. Karl Lamb, is now operating the plant as a custom mill. The plant was built to treat a dump containing 80,000 tons of low-grade material, but so far has operated only as a custom mill. The ore is gold-silver in about equal proportions in value, and nothing of less value than \$20 is purchased, while some of the sorted ores are worth \$100 per ton. The plant is to be increased in capacity and a modern slime plant and filter added, so that a profit can be made on the low-grade material which it is expected will average \$10 per ton. The district has a big record and possesses several mines which will probably now be reopened, as there is an opportunity to dispose of ores. The camp is some 30 miles from Marquesa, the nearest railway station, and is at an elevation of 5000 ft. The purchase price was \$30,000 (U. S. cy.), besides which it will be necessary to install more equipment.

Santiago, Chile, October 3.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING CORPORATION—AUTHORITY TO MORTGAGE

The defense that a mortgage upon the mines of a coal mining company had been executed by the directors without a vote of the stockholders as required by the Colorado statute, cannot be raised by the corporation as a defense in an action to foreclose the mortgage, but is available only to the stockholders.

Firestone Coal Co. v. McKissick, (Colorado) 134 Pacific, 147. July 14, 1913.

NEVADA CORPORATIONS—OFFICERS

Under the laws of Nevada, a corporation organized in that state must have not less than three trustees or directors, who in turn must elect a president, a secretary, and a treasurer. There may be as many additional directors and officers as the corporate by-laws provide for. The duties of these officers are not prescribed by law except that the secretary is required (Section 1126 Revised Laws) to record all the acts and votes of the corporation and its members and stockholders in a book kept for that purpose.

PHOSPHATE LEASE—ROYALTIES

Where a lease conveying the right to mine and remove all the merchantable phosphate rock from beneath certain property, provided that in case the lessee should mine and ship less than a specified minimum amount, that he should nevertheless pay a specified sum every quarter as 'ground rent,' if after the lease is executed it turns out that there is no phosphate rock on the land, the lessee is excused from paying any royalty or ground rent whatever. The lease was held to have assumed and contemplated the existence of the rock as its subject matter, and when that failed the obligation failed.

Ross v. Savage (Florida), 63 Southern, 148. July 1, 1913.

MINING LEASE—CONSTRUCTION

Where under a lease of certain lands for the purpose of mining coal and manufacturing coke, the lessee proceeded to construct certain buildings on the land for the future use of its employees, and pending such use leased said buildings to another company without accounting to the lessor of the land for the rents from the buildings so leased, there being a clause in the original lease permitting the lessee to exercise any rights not reserved by the lessor and no inhibition against leasing buildings constructed by the lessee, it was held that the law would not imply such an inhibition and that no accounting for rents could be required.

Stonegreep Colliery Co. v. Kelly & Vicars (Virginia), 79 Southeastern, 341. Sept. 11, 1913.

SEVERANCE OF MINERAL RIGHTS—CO-TENANTS

The general owner or owners of land may grant all the minerals therein or any particular species of them, while still retaining title to the surface, or they may grant the land and reserve the minerals, thus creating a separate estate in the minerals, distinct from the land in which they are found, but one of two or more tenants in common cannot convey his share by metes and bounds, nor can he convey the mineral rights and reserve the surface to the prejudice of his co-owners. The grantee under such a deed to mineral rights from one of several tenants in common under the law of Virginia becomes himself a tenant in common with the others. Where a stranger to the title thereafter accepts a deed from all the remaining co-tenants, purporting to cover the entire tract of land, goes into possession under such deed and to all intents and purposes remains the sole owner in fee and in possession for more than 30 years continuously thereafter, he is held to have acquired by adverse possession, prescriptive title to the mineral rights as against the grantee under the said deed of mineral rights from one of the original co-tenants.

Virginia Coal & Iron Co. v. Hylton (Virginia) 79 Southeastern, 337. Sept. 11, 1913.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

F. G. COTTRELL has gone to Butte.

MAX. J. WELCH is at Los Angeles.

HARRY R. JOHNSON was in San Francisco Monday.

C. C. BRAYTON has returned from Nome for the winter.

F. B. WEEKS was in San Francisco from Shasta county this week.

SEELEY W. MUDD was in San Francisco Thursday from Los Angeles.

LEO VON ROSENBERG has been in Nevada and Sierra counties, California, recently.

L. V. WATERHOUSE is now at Queenstown, Tasmania, for the Mt. Lyell M. & R. Company.

M. W. VON BERNEWITZ is visiting the Mother Lode mines and the dredging fields of California.

FRANCIS DENNIS is in New York, having completed his professional work in North Carolina.

W. A. WILLIAMS has returned from Arizona and will make San Francisco headquarters hereafter.

GEORGE W. EVANS has completed his work at Matanuska, Alaska, for the Bureau of Mines and has returned to Seattle.

C. E. GAUNSKY, JR., has returned from Bodie, where he has been acting as superintendent for the Standard Consolidated.

E. V. DAVELER, formerly mill superintendent for the Ray Consolidated, is now mill superintendent for the Alaska Gastineau.

J. E. BREAKELL is general superintendent for the Socorro G. & S. M., Ltd., in Honduras. W. S. MANN is erecting the cyanide plant.

R. T. MISHLER is assistant general manager for the Tigre Mining Co., and not superintendent as erroneously announced October 30.

R. N. DICKMAN has joined the staff of R. W. Hunt & Co., and is engaged in examining gypsum and coal properties in western Canada at present.

HENNER JENNINGS, W. J. RICHARDS, A. E. MONTGOMERY, and M. E. KEMMERER were elected directors of the American Mining Congress at its meeting at Philadelphia last week.

Obituary

ARTHUR WILKINSON, a member of the Institution of Mining and Metallurgy, and consulting engineer for the Colombian M. & E. Co., and the Sekondi & Tarkwa Co., Ltd., died September 29.

M. JASPER McDONALD, one of the pioneer miners of California, died suddenly on the night of October 30, in his eighty-third year. Mr. McDonald was a well known figure on the Stock Exchange of San Francisco, of which he had been a member for many years. For more than 20 years he had operated the Keystone mine in Amador county, succeeding his brother James. He also was owner of several other mining properties in various parts of the state and was one of the early-day operators on the Comstock Lode. He was for many years an active member of the Bohemian Club of San Francisco.

FRANK P. SWINDLER, a resident of Salt Lake City, died at Los Angeles, October 13, from cardiac asthma due to inhalation of stone dust while operating a dry-crushing mill years ago. The dust in his lungs had given him much trouble during the past few years, although few of his friends were aware of his condition. He was a native of Pennsylvania and before going to Utah was identified with mining at Leadville. He was well known in the West, having held positions as general manager of the De La Mar property in Nevada, in behalf of the Bamburger interests general manager of the Ohio Copper Co. at Bingham, manager of the Opex company at Tintic, and had examined and reported on many properties.

The Metal Markets

LOCAL METAL PRICES			
San Francisco, November 6.			
Antimony.....	10-10½c	Quicksilver (flask).....	\$39
Electrolytic copper.....	17½-17¾c	Tin.....	44-45½c

Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.

EASTERN METAL MARKETS
(By wire from New York.)

NEW YORK, November 5.—The fourth being a holiday, public interest was devoted solely to the elections and the market received no consideration, everyone taking a day off to elect a new mayor. The copper market opened weak today and but few sales are reported. Lead is active and spelter is quiet. The tin market is quiet with spot and November quoted at 40.15 to 40.35. Trading in tin has been moderately active but the market has been subject to irregular movements, this being especially true of the London market.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.			Average week ending

Samuel Montagu & Co. report October 23 as follows: Lack of animation continued to characterize the market for the greater part of the week, although the undertone remained steady. Until today, movements in prices had been confined within very narrow limits; in fact, the total variation in the cash price since the beginning of the month had been only 5/16d. China was inclined to figure as a seller, but 'bear' covering operations and a demand for the Continent and elsewhere was sufficient to absorb the modest amounts available. Today heavy offerings of silver from China and India, coming on an unwilling market, resulted in a sharp fall of 3/8d. in the cash quotation, and 5/16d. in that for two months. During the last six weeks, bar silver to the value of over £300,000 has been shipped to Germany and Russia. Spot supplies remain relatively scarce, and the premium on cash silver rose to 1/8d. on Oct. 20, fell back the following day to 1/16d., and repeated the movements on Oct. 22 and 23. It is expected that a substantial shipment will be made by this week's P. & O. steamer for account of the Indian Government. The Indian currency return received on Oct. 17 showed an increase in the holding of silver rupees of 145 lacs, which is to be accounted for by the release of 150 lacs of silver rupees from the standard reserve, by the transfer to that reserve of 150 lacs of rupees in gold from the holding of 'gold in India.' The stock in Shanghai has fallen from £6,220,000 to £6,195,000 and that in Bombay from £420,000 to £365,000, while the offtake at the latter place is rather better at 75 bars per day. A shipment of £50,000 of silver has been made during the week from San Francisco to Hongkong. The quotations today for cash and 2 months delivery are 7/16d. lower than those fixed a week ago.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York

market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

Date.		Average week ending
Oct. 30.....	16.30	Sept. 24.....16.41
" 31.....	16.30	Oct. 1.....16.29
Nov. 1.....	16.25	" 8.....16.27

" 3.....	16.20	" 22.....16.38
" 4 Holiday		" 29.....16.55
" 5.....	16.20	Nov. 5.....16.25

The New York market was featureless last week, and at the end of October the only interest displayed was in speculating regarding the statistics for September, which will be issued on Oct. 7, as Oct. 8 falls on Sunday. Throughout the early part of last week prices were held by sellers at 16½c., not much 'second hand' copper being offered. At the middle of the week there was a fall in price on the London market, which is speculative, but there was no change here, and the week closed with the nominal quotations unchanged and but little business being done. Much has been made of the fact that the world's visible supply on Oct. 1 was equal to only about 12 days consumption, and the strikes at Rio Tinto and on the Cerro de Pasco railway have been featured as 'bull' arguments on the price of copper. Less attention is called to the fact that the European demand is slackening, exports during October having been but 27,689 tons, as compared with 24,670 tons last year, and the American demand is very poor at present. Some of the mills in the Naugatuck valley are only working at half capacity, and the American Brass Co., one of the largest consumers, has greatly slackened its demand. We do not look for any marked improvement in the price of copper this month.

ZINC

Zinc is quoted as spelter, standard Western brands St. Louis delivery, in cents per pound.

Date.			Average week ending	
Oct. 30.....	5.13		Sept. 21.....	5.50
" 31.....	5.12		Oct. 1.....	5.85

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending		Oct. 22.....	39.00
Oct. 8.....	29.50	" 29.....	40.00
" 15.....	39.00	Nov. 5.....	39.00

L. Vogelstein & Co.'s Metal Report*

TIN

There has been an almost entire absence of demand for tin from America. This is partly due to the generally pessimistic feeling pervading all markets and also to conditions specifically affecting tin—chiefly the fact that tin plate prices for the ensuing year have not yet been fixed. Last year they were fixed as early as September. Immediately this is done, a large volume of orders automatically goes on the tin plate makers' books. As soon as there is a change in this respect, a greater activity is expected, and it is not impossible that higher prices will prevail. It must be admitted that the statistical position is not encouraging. Deliveries here in the last quarter of the year will probably be 1000 tons less than during the corresponding period of 1912, and London, Holland, and the Continent will shrink a like amount. Consequently the visible supply December 31 is not likely to show any decrease compared to September 30, whereas last year there was a decrease of 2000 tons.

LEAD

While sentiment in respect to lead, as is the case with other metals, is in a depressed state and buying is only of a hand-to-mouth character, it is doubtful if prices will go any lower. This opinion is based on the fact that the foreign and domestic markets are now on almost an exact parity, and any decline here, unless coincident with lower prices abroad, will be followed by exports. The New York price of 4.35 for common desilverized lead is equivalent to £20, and lead has been selling in England and on the Continent at £20 or better for the past six months. Present high prices abroad are charged principally to the smaller quantities coming from Mexico. According to reliable authorities, the normal production of that country, approximately 10,000 tons per month, has been reduced about 75%. There is no promise of an early solution of the Mexican troubles.

Concerning the domestic situation, there is every reason to believe that consumption exceeded production by a wide margin in 1912. This year, while consumption has only slightly increased, supplies promise to be larger—not sufficiently so to make the situation unsound, but enough to make it easy—especially in view of the lack of confidence now prevailing and the almost universal indisposition to undertake future commitments.

SPELTER

Spelter has, as usual, fluctuated over a wide range of prices. It opened above 7c., went below 5c., reacted to about 5½c. or 5¾c., dropped back to 5¼c., and is now about 5¼ to 5¾c. Subsequent to Government statistics covering the first half of the year, no authentic information is obtainable concerning the position of this industry. These statistics disclosed a slight increase in production and considerable falling off in deliveries.

*Circular of October 27.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN counteracting acidity 1.4 parts of lime, or 2.6 parts of carbonate of soda, is equivalent to 1 part of caustic soda.

PUMICE is not a material sold in the general market, and prices cannot be quoted. Manufacturers who use it for making various sorts of scouring and polishing preparations, usually control their own supply or buy direct from the producer.

THE output of manganese alloys, ferromanganese, and spiegeleisen from American works last year was 227,939 long tons, against 178,615 tons in 1911, and shows a healthy activity in this branch of the mining industry. In addition, more than 100,000 tons was imported.

IRON ORE reserves to the extent of 30% of the total available are owned in Michigan by the United States Steel Corporation, according to C. K. Leith. The Cleveland-Cliffs Co. owns about twice as much old range ore as the Corporation, according to the same authority.

IRON PYRITE has little or no effect on cyanide, and the cyanidation of a highly pyritic ore of this nature presents no difficulties provided that partial oxidization of the pyrites has not preceded treatment, and that the ore has been fine enough ground to expose the gold or silver to the solvent action of the solution.

COPIES of patents granted by the United States may be obtained at small expense direct from the Commissioner of Patents at Washington, D. C., provided the number of the patent is known. Otherwise it is best to make application to a patent attorney who will make search of the files and obtain the needed information.

TRAINLOADS have increased rapidly upon American railroads in recent years, due largely to the initiative of James J. Hill of the Great Northern. On that system of railroads the average trainload has increased from 357 tons in 1900 to 635 in 1913. An important factor in bringing up this average has been the development of the iron ore traffic in which the average trainload is approximately 2200 tons.

IRON ORE forms 50% of the revenue tonnage of the Great Northern railroad, despite the extent of that system. The profit in handling it amounts to 12% of the gross and 20% of the net earnings. One mile in the iron country contributes the same number of carloads as required to handle the whole wheat crop of North Dakota. The total iron ore handled by this road this year amounted to 15,000,000 tons, equal to 65% of the total wheat crop of the United States.

IN estimating the amount of gold in a specimen, as shown on this page in the issue of November 1, where g_1 represents the specific gravity of the specimen, g_2 the specific gravity of gold, and g_3 the specific gravity of quartz, and x the percentage of gold in the specimen, according to L. J. Hohl, of San Francisco, the equation for x would be:

$$xg_2 + (100 - x)g_3 = 100g_1$$

from which

$$x = \frac{100(g_1 - g_3)}{g_2 - g_3}$$

BRAZILIAN iron ores grade up to 69% and are very low in phosphorous, according to C. K. Leith. In the Rio doce valley he estimates that 600,000,000 tons of high-grade ore is available above the lowest outcrop, and that above a depth of 600 ft. the reserve amounts to 1,000,000,000 tons. Of soft ore analyzing about 64%, there is in the same locality 365,000,000 tons proved and about 1,000,000,000 tons

probable above 600 ft. depth. In Brazil as a whole there are estimated to be 4,000,000,000 tons containing 64% iron or more.

THE plasticity of clay is directly determined by the character and amount of the colloid matter in the clay, consequently, by measuring and controlling the colloid matter present, the plasticity of the clay will be easier controlled, according to H. E. Ashley, of the Bureau of Standards, Washington, D. C. The process of coarsening or sedimentation of particles in pulp is commonly termed flocculation, the opposite process, deflocculation. The latter term has come to mean a decrease in the rate of clearing, and suspensions are said to be deflocculated when they settle slowly or not at all. These terms are relative only, as there is no direct measure of the extent of flocculation. It is, however, convenient to speak of the degree of flocculation. Thus, when it is said that addition of an alkali decreases the degree of flocculation, it is understood that an alkali tends to deflocculate a pulp; or, in other words, to decrease the size of the dispersed particles and so to render the suspension more permanent. The deflocculators, which comprise only the hydroxides, carbonates, and other highly hydrolyzed salts of the alkali metals, all of which have a strong alkaline reaction, also show a 'threshold concentration' effect.

PICKING BELTS of various types are used at many mines. Below is presented a plan and elevation of a particularly good design adopted by the Mitsui Co. at the Milke colliery in southern Japan. The coal is here fed in continuous stream to a horizontal pan conveyor divided into three parallel channels. The pickers, in this case neatly dressed and white-capped girls, sit facing their work with a stream of coal before them. The waste channel is in the centre. Consequently there is no need for awkward turning or throwing back of refuse. With the simplest

and most efficient of motions, each girl picks the slate from the stream of coal in front, raises it the few inches necessary, and drops it into the middle channel of the conveyor. As the coal is dropped upon the conveyor through a hooded chute and the picking shed is large, well lighted, and well ventilated, the working place is clean and cheerful. There are 40 pickers. The total amount handled is 2200 tons per day, equivalent to 55 tons per worker. From this 2½% or 1½ tons of waste per girl is sorted out. The wages are 17½ to 20 cents per 8-hour shift; but this is not the whole compensation, since, as is customary in Japan, the Company assumes responsibility and considerable expense for living conditions.

Book Reviews

MINERAL DEPOSITS. By Waldemar Lindgren. P. 883. Ill., index. McGraw-Hill Book Co., New York, 1913. For sale by *Mining and Scientific Press*. Price \$5.

When Mr. Lindgren resigned as chief geologist of the United States Geological Survey, there was consolation for the loss sustained by the public service in the thought that he would now find time to digest and summarize, at least in part, his many observations and the results of his wide reading. This he has now begun to do, and in the volume under review he has brought together in one orderly whole much of his material, at the same time that he has reduced to consistency and order much contributed to the literature of mineral deposits by his fellow-workers. The result is a book of undoubted significance; one which is likely to mark a definite change in the current of study. Not that there is in it much that has not been previously printed, but that the facts and conclusions are so arranged as to admit of intelligent comparison and to throw new light upon them.

It is interesting to note that Mr. Lindgren has chosen the title 'Mineral Deposits' rather than 'Ore Deposits.' Thus he reverts to the earlier point of view such as Whitney had in mind in 1855 when he wrote his 'Metallic Wealth of the United States'—that is, the unity of the subject. There is no real reason, perhaps, why the genesis of the non-metallic minerals should be studied separately from that of the metallic. Indeed, it is often difficult to say when a given deposit belongs with one rather than the other, since a vein worked for its metallic content at one time may later become chiefly valuable for the non-metallic gangue. It is also true that many metals, such as sodium, being little used in their elemental form, the earthy mineral in which they occur becomes of chief value and colors the popular conception of the character of the deposit. Originally the veins of southern Illinois were worked for lead, which is present in the form of galena; now, and for many years past, the lead has been incidental and the fluorspar is most important. The problems of occurrence and genesis have, however, remained the same. Under any system of study, these veins must be compared with ordinary lead-silver veins in the West rather than with coal beds or salt marshes. Mr. Lindgren makes the attempt to bring all this material together, though even he excludes coal and certain others including gilsonite which is found in veins as typical as ever formed of quartz. The chapters in which the non-metallics are treated, while interesting from the fact that they reflect a point of view not usual in the study of these minerals, are by no means as strong as are the others in which Mr. Lindgren discusses the things regarding which he has a first-hand and masterly knowledge.

Another feature of the book is the abandonment of the older classifications and the bold following of a genetic scheme. As Mr. Lindgren states, "opinions may differ as to whether our present knowledge is sufficient for such an undertaking." Our own is that, while there are large gaps in our knowledge and there will be much uncertainty as to the placing of many important deposits in any genetic scheme, the one here proposed is in the line of progress; that, indeed, it is much more than an attempt to classify: it is a working and workable outline. We may shift the position of the units, we may even deny the integrity of certain of the proposed groups, but in the main the usefulness of the plan, as well as the sound knowledge of its author, will lead to its adoption.

Following eleven introductory chapters in which are discussed such matters as the deposition of minerals, the flow, composition, origin, and chemical work of underground waters, the relations of mineral deposits to mineral springs, the folding and faulting of rocks, the openings in rocks, the form, structure, and texture of mineral deposits, and ore-shoots, the classification itself is outlined and typical examples of deposits falling in each class are described in fifteen chapters. Interest centres mainly upon

these chapters in which the various deposits are described and classified. As to the first, "deposits formed by mechanical processes of transportation and concentration," there is little room for differences of opinion, though it is surprising that the Rand gold deposits are discussed in this chapter in view of the apparent present preponderance of evidence in favor of the introduction of gold, the significant element, after the formation of the banket. The "deposits produced by chemical processes of concentration in bodies of surface water by reactions between solutions" include the larger number of non-metallic deposits whose discussion in this connection has been noted as unusual. This, and the succeeding chapter on "deposits formed by evaporation of bodies of surface waters," are possibly the least satisfactory in the book. The "mineral deposits resulting from processes of rock decay and weathering" include many well known occurrences. We are glad to see the inclusion of a number to which has been occasionally ascribed a more complex and mysterious origin, and emphasis placed upon the capacity of simple existing agencies to produce the concentrations. Just why it is necessary to infer that most of the bauxite deposits of the United States were formed "under climatic conditions different from those now prevailing" is not entirely clear.

Deposits formed by concentration of substances contained in the body of the rocks in which the ores are found, are further divided into (a) those formed by means of circulating waters, (b) those resulting from regional metamorphism, and (c) copper deposits formed by zeolitization of basic lavas. There will be much confusion between the first mentioned class and the one next to follow, that is, those formed in sedimentary rocks by circulating waters but without the influence of igneous activity. It is, to us at least, a matter of grave doubt whether a circulation active enough to concentrate into a workable body of ore the minutely disseminated particles of mineral found in sedimentary rocks, is in fact often confined to one formation, and whether, in those cases where it does occur, there is any significance to be attached to the fact. Similarly, we doubt the value of the class assigned to deposits formed by regional metamorphism. While perhaps pressure and temperature changes might convert a rock into an ore, we can not conceive of any considerable body being formed except by transfer of material, in which case surely solutions would come into play. Mr. Lindgren seems to have found this a difficulty, since even with his wide knowledge of deposits and literature, he is able to assign but few deposits to this class.

When the group of deposits formed under the influence of igneous intrusions is taken up, Mr. Lindgren places the bulk in three classes, and states frankly that opinion is divided as to the origin of the heated ascending waters which are the main agency in their formation. In his discrimination of these three classes lies, we believe, one of the main practical results of his work, and we would call attention to the fact that this assignment of individual deposits rests upon no theoretical or *a priori* grounds, but upon the solid basis of thorough geological studies of the regions involved. The Cripple Creek ores are placed in the class formed at shallow depths at which presumably ascending and descending waters would mingle, not because of any special peculiarity of the deposits, but because reconstruction of the Cripple Creek volcanic cone shows that the present surface is probably less than 1500 ft. below the original surface. In the same fashion, the locus of the Mother Lode ores of California in the intermediate zone, is based upon reconstruction of the geology of the Sierra Nevada. These depths once fixed upon independent evidence, certain conclusions as to pressure became permissible. The third group is that of deposits formed by processes of igneous metamorphism, or the deep-seated ores of the general class formed by ascending waters. There are still the mineral deposits of the pegmatite dikes, and the minerals deposits formed by concentration in molten magmas or, as others prefer to call them, the magmatic segregations. In treating all these classes, Mr. Lindgren is notably conservative. He allows no single theory to

run away with him, and yet he makes fairly definite statements and builds up clear concepts.

Metamorphosed deposits are treated separately, and the oxidation of ores is discussed as a later and separate process rather than as part of ore genesis itself. There are those that argue that since it was usually the secondary enrichment which converted the mineral deposit into an ore deposit, that process is the one of most significance and should be made the basis of classification. Mr. Lindgren evidently thinks otherwise; it is a case where opinions differ. The book closes with a chapter on the calculation of rock analyses, and a serviceable index.

The work as a whole is one that will be widely read and used. Aside from the new basis upon which it has been built, and despite the fact that examples only are described in each class, it is probably the best general text on the subject. European writers have but a scanty knowledge of American ore occurrences, though America is, as yet, the great field for mineral deposits. Americans have generally only a slight knowledge of either European localities or literature, but Mr. Lindgren is well equipped in both particulars, and we anticipate that the value of his book will be recognized abroad as generously as it is sure to be here at home.

H. F. B.

LETTERS AND RECOLLECTIONS OF ALEXANDER AGASSIZ. By G. R. Agassiz. P. 454. Portrait and illustrations. Houghton, Mifflin & Co., Cambridge, 1913. For sale by the *Mining and Scientific Press*. Price \$3.50.

Some one has said, that to make an interesting subject for a biography, one must be of an "experiencing nature." To the commercial traveler, a trip to the city is a trip to the city—only that and nothing more; but to the lone farm woman starved for company, a trip to the city is a voyage of adventure into the unknown, a dating point in history. There are a chosen few to whom life is of such zest or whose intellectual horizon is so wide, that the whole of life is an experience, and the record of such men and their doings is more fascinating than the made-up adventures of a most heroic prisoner in Zenda. Alexander Agassiz was of that type. His biography is worth reading because he ventured into many domains of knowledge; and he had not only the intellectual curiosity that led him into them, but the intellectual power necessary to make a place for himself in each. As his son and biographer says, "in the world of affairs he was known as an extremely capable and successful mining man, who was said to employ his leisure moments in some sort of scientific study," but to the morphologist, zoologist, geologist, and museum specialist, he spoke each in his own tongue, and to each his relation to the great Calumet & Hecla mine was but a fortunate accident that gave him the means to do great things. While the relation was no accident, the scientist judged Agassiz better than the world of business. We believe that he will have his wish and will be best and longest remembered, not as an eccentric American millionaire who gave money to science, but as one who, having time and means for a free decision, chose to give work and money to advancement of abstract science as the thing most worth while. Already to the younger mining engineers, Agassiz's connection with the inception of the Calumet & Hecla is but a vague tradition, but there is no chapter in all this fascinating book more worth reading than the story of how this young museum assistant (working at the time for \$1500 per year and spending much of that on his work) rescued and soundly established a nearly ruined property. Agassiz came to the Calumet & Hecla with an especial aptitude for figures, a sound technical training obtained at Lawrence Scientific School, and with some experience in mining acquired in the coal mines of Pennsylvania. Furthermore, he had the best of incentives to make good, since his own and his friends' money and reputation were at stake. He had to succeed, and he did succeed. In 1867, northern Michigan was not the pleasant accessible country that we now know, and conditions were more nearly comparable to those now surrounding development of mines in Alaska, with the added handicap of a much smaller fund of technical knowledge from which

to draw and a very much smaller number of trained men. How serious was the first drawback may be indicated by the fact that the whole enterprise was nearly ruined through the attempt to use rolls in place of stamps in the Calumet mill; an attempt made against Agassiz's judgment and forced by conditions as he found them at the mine. Agassiz had to meet all the usual difficulties incident to a new enterprise in an unsettled country, including a dishonest predecessor, incapable assistants, and a hostile local population. Nothing was lacking, even to the proverbial blowing up of the dam of the mill pond when the plant was finally ready to run. This determined young man, who later became the millionaire savant and on the deck of his private yacht pored over the zoological treasures brought up by sounding the depths of the sea, had his own hard years even as other mining men. He slept with his clothes on when and where he could, he did three men's work by day and wrote his reports by night, and he ventured all he had and all he could borrow on the accuracy of his judgment and the strength of his purpose—even as other young engineers have done since, are doing now, and will continue to do so long as mining continues to be an alluring contest between trained brain of man and the stubbornness of nature. How well Agassiz succeeded is an old story, and to the world at large the hundred odd millions of dollars paid in dividends is the measure of his reward for the heavy toll the mine took of the man. We fancy that to him the victory as well as the money counted for much, for to the year of his death Agassiz kept his fingers on the keys and annually went back to study the great property between which and him there had been so much of give and take. The whole story of his life, from the small schoolboy walking from Freiburg to Lausanne because he had no money for stage fares, to the later years in the Newport home when the exact dressing of a dinner table was a matter of moment, is a captivating account of the possibilities of life in America when life meets one strong enough to fight to mastery.

IF a hippopotamus requires two bales of jungle grass per day, how many of this particular type of pachyderms will be needed to keep the banks of Lake Gatun free of tropical vegetation?

PLANS are already being made for the third annual mining exhibition under the auspices of the Chemical, Metallurgical and Mining Society of South Africa, which will be held at Johannesburg next April. The two previous exhibitions were visited by 30,000 persons, and the next is already arousing lively antieipations. Intending exhibitors are invited to correspond with the secretary of the society, Mr. Fred Rowland.

IN the installment of Mr. C. B. Horwood's disension of the Rand bankets printed this week will be found charts and diagrams of unusual interest. They show representative relations of rich to poor ore in depth and along the strike in graphic form. They are of especial value in that they are based upon tracings from working maps. To American engineers, at least, no such wealth of material regarding the Rand orehodies has been previously available.

THE Fifth National Conservation Congress will meet, November 18 to 20, inclusive, at Washington. The meeting will be devoted largely to the consideration of forest conservation, but other problems such as the development of hydro-electric power, the utilization of non-agricultural lands, and the availability of water for irrigation will be discussed. When it is known that we are using three times as much timber as grows each year, that only 40 to 70 per cent of each tree that is cut down is utilized, and that fire destroys the equivalent of each year's growth, the importance of the conservation movement is realized.

NORTH DAKOTA geology was recently summarized in an excellent short sketch, accompanied by a geological map of the state, the whole prepared by Mr. A. G. Leonard, state geologist. This was published in *The Quarterly Journal* of the University of North Dakota, and while this is eommendable as emphasizing the relations of the university to research as well as teaching, it is also regrettable that anything of so much general interest should be buried in a local publication. There are so many places now for publication that it is all but impossible to keep track of the literature of any subject, and the large number of unspecialized periodicals is in some ways more of a nuisance than a help.

COLORADO members of the A. I. M. E. met at a well attended dinner at Denver last week. We shall present an account of the meeting next week.

THE article upon 'Lead Salts in Cyanidation' that we print this week is of the type that we like to publish. It is based upon correspondence extending over a year and into all quarters of the globe. While Mr. von Bernewitz writes the article the facts presented have been obtained at first hand from a hundred or more metallurgists. Each has contributed from his experience to the common fund of information, and the whole constitutes a comprehensive and exact record of fact based upon the best modern practice.

FIGURES from the payroll of the Rouse mine of the Colorado Fuel & Iron Company for the month of August were recently made public as an example of the wages being paid to coal miners in Huerfano county. The figures as published show that the average wage for the month of August was \$4.41 per day. Eleven of the men earned between \$100 and \$110 for the month; 13 between \$110 and \$120; 15 between \$120 and \$130; 6 between \$130 and \$140; 8 between \$140 and \$150; 9 between \$150 and \$160; 5 between \$160 and \$170; and 2 over \$170. Seventy-two miners who worked 25 and 26 days averaged \$4.75 per day. The miners have an eight-hour day and are paid twice each month. All of the men on the payroll could have worked 26 days during the month of August if they had so desired. If this is a 'starvation wage' there is surely a very large percentage of the American people who are destitute.

THE quest for new gold deposits and the seeming failure to discover any new goldfields of importance, together with the limited ore reserves known, periodically lead to a discussion as to where the future gold supply is to come from. As the future yield cannot be predicted with the certainty of a wheat crop, the answer is not to be had and probably never will be made. The alchemist sought a solution, and there is little doubt but that King Solomon puzzled over the same question as he saw his mines being exhausted. The fact remains that the law of supply and demand has been maintained until today, and there is every reason to believe that the future, at least for many years to come, will take care of itself. With Asia, a large part of Africa, Mexico, Central and South America, Canada, Alaska, and other gold-producing countries, to use a trite expression, 'scarcely scratched,' it does not require a great deal of optimism to believe that this demand will be met for many years to come. It has been the history of the industry that as old mines become exhausted, new mines are developed, and with the vast tracts of unexplored territory still at man's disposal, it is reasonable to believe that there are still great ore reserves which will be found when necessity demands. While a Rand, a Klondike, or a Kalgoorlie is not found every time a prospector goes into the hills, indeed may never be found again, yet new mines are being developed. When one region is on the decline, others are increasing their production and the balance is maintained. In our current issue the

expansion of the gold-mining industry in Rhodesia is recorded by Mr. Owen Letcher. The new treatment plants and increasing ore reserves portend a healthy state of the industry and a future of promise. The production statistics of Rhodesia show that during the month of September there were two hundred gold producers with a total production of 59,535 oz., valued at £250,430. The increasing importance of the industry is evidenced by the regular increase in production for the past three years, which show a production of £2,568,198 for 1910, £2,647,894 for 1911, and £2,707,368 for 1912. The production for the present year to October 1 was £2,162,478, at which rate the production for 1913 will amount to £2,883,300. Rhodesia has been considered a disappointment, but production is growing and that country does not stand alone in this particular. There is reason to believe that the automatic adjustment which obtains with all the other commodities will continue to hold in meeting the world's demand for gold.

EVEN the most modest man is occasionally forced into the lime light when his deeds are worthy, and certainly Mr. Willett G. Miller has done things worthy of the recognition given by his fellow mining men at the Toronto Club the week before last. The occasion was a complimentary dinner and presentation of a portrait—to the man "whose great knowledge and ripe experience had been so freely, generously, and unselfishly given to the development of the mining industry in Ontario." It was characteristic that in responding to the presentation speech, Mr. Miller said that he preferred to regard the tribute not as a recognition of his personal services, but as a recognition of a period of great mining development in the province. Mr. Miller was the real discoverer of Cobalt. It is true that a blacksmith and one other had found veins and picked out ore before Mr. Miller arrived on the ground in the course of his regular geological survey work. Neither of the 'discoverers,' however, knew what he had found. The unusual combination of minerals was beyond the knowledge, at that time, of any but a well trained mineralogist. There was every opportunity for a short cut to fortune by the man who had the knowledge and who was on the ground. Mr. Miller, however, had other ideals. He gave the prospectors full information and through the years since has worked constantly and ably to promote the sound development of the mining industry of his province. As a result he has to an unusual degree the respect and confidence of a wide circle of friends, and who shall say that is not the truest and best reward.

Currency Problems In the Orient

India and China stand in a peculiar position in the matter of international monetary relations. Both countries are large exporters of raw materials and heavy buyers of manufactures; within the boundaries of each, silver currency and bullion is the chief medium of exchange, and neither is a large producer of that metal. These two countries are therefore the chief markets for silver. The resulting situation may be regarded as an interesting ex-

ample of the law of compensations, since when silver is cheap India and China are at a considerable trade advantage, as their exports are sold on a gold basis and paid for in silver, and the native exporter receives a considerably larger sum in the medium with which he makes his purchases. This stimulates exports to such an extent that the demand for silver causes it to increase in price. Even so, the price of silver varies widely, and the resultant effect is bad for trade, since it renders the export business highly speculative. The fluctuation in the price of silver sometimes is as much as 15 per cent in a comparatively brief period, and in making long-time contracts merchants are obliged to make the margin between their buying and selling prices wide enough to cover probable fluctuations. For example, an exporter at Shanghai may agree to make monthly shipments of goods of standard quality at a price in gold which will net him 10,000 local silver dollars. A few months later the return to him may be 9,000 or 11,000 local silver dollars. Ordinary commerce thus takes on the aspect of lively speculation, a state of affairs which does not conduce to the steady growth of business, and which frequently leads to disastrous failure on the part of any firm which is without sufficiently strong financial backing to stand a long period of depression.

The placing of both China and India upon a gold basis has often been proposed, and some years ago the government of China engaged Mr. Jeremiah Jenks, then professor in Cornell University, to study the problem and suggest means for its solution. More recently Mr. M. de P. Webb has advocated the creation of a central state bank in India, the building of gold mints, and the use of gold currency. By increasing the banking habit among the population, who now hoard precious metal, it would be released to serve as the basis of credits. Similarly, it has been proposed to make gold the basis of currency in China, where a central state bank is already in existence, but which has not as yet attained dominance in the financial situation in that country. The difficulty in bringing about any such radical change in the financial relations within these populous countries is threefold. The habits of the people are not subject to easy change except where the change appeals to them as immediately advantageous; there is a large element in the population, made up of small bankers and money-changers chiefly, who have everything to lose and nothing to gain by the change; and neither country possesses a large gold reserve on which to base a gold currency. To obtain this gold would require competing for it in the money markets of the world, where every other country is now trying to obtain it. According to the theories held by some, this would make gold dearer and commodities cheaper, so that we all should benefit by it; but this is an argument with little force of appeal to those who stand to lose by it, and who are most effective in preventing any such change being put into effect. There can be little doubt that both India and China would benefit from the adoption of the gold standard, and it is at least doubtful whether silver would greatly decrease in price as a result, since in both countries it would be still required for subsidiary coinage. China has a large foreign debt

of which the interest and principal are payable in gold, while the income of the government is in silver. It is possible that when centralization of government in that new republic has progressed a little farther, it will be possible to place the central bank upon a gold basis and thus lead up to its adoption throughout the country.

Workingmen's Compensation

Laws designed to secure to workingmen adequate compensation for industrial accidents, and to protect those dependent upon them from want in case of the death of a worker, are being passed in many states and countries. The old theory of the law was that each should look out for himself, and there is no question but that this makes for careful and independent workmen. There are, however, a large number of accidents that can not be traced to the neglect or ignorance of the one injured, and modern industrial conditions do not permit to each man that freedom of choice of occupations that is essential to fairness in application of the doctrine of assumed risk. It is also true that each of us is careless at some time. It is impossible for even the best man to be keenly alert every instant, and a serious accident, involving hundreds of innocent people, may result from but the briefest inattention. Accidents are much more frequent in some industries than in others, and under conditions that have obtained in the past a brutal or careless employer, or a group of poorly trained and reckless workingmen, could burden a whole community with cripples and dependents.

The present tendency is to make each industry carry its own burden, as nearly as may be; to sweep aside the old 'fellow-servant' doctrine, that of 'assumed risk,' and the plea of 'contributory negligence'; and to recognize that a certain number of accidents are as inevitable as a regular amount of wasted material in each industry. The principles underlying the new laws are everywhere commended, but there is still much difference of opinion as to the best practice to adopt. We print this week a general statement of results in Germany, where the system has been more widely adopted than in any other country. Apparently, the results are favorable, and this conclusion is borne out by the observations of numerous critics. It by no means follows that the same system will produce equally good results in the United States, and it is just as well that each state is at least attempting to adapt rather than adopt the code.

The Boynton workmen's compensation act, which goes into effect in California on January 1, 1914, is one of the broadest that has been enacted relating to the compensation, insurance, and industrial safety of employees. The object of the act is to create a liability on the part of all employers to compensate injured employees and their dependents for accidental injury or death, irrespective of the fault of either party. The act further provides the means and method for enforcing this liability. The act provides for the creation of a state compensation insurance fund to insure employers against such liability, provides for its administra-

tion, and regulates accident and liability insurance by other insurance carriers. The act also contains elaborate provisions for safety in all employments and places of employment in the state. It requires reports on industrial accidents and provides for penalties where the provisions have not been complied with. An Industrial Accident Commission will be created, the organization of which and its powers and duties are designated.

Under this act, liability for compensation shall, without regard to negligence, exist against an employer for any personal injury sustained by his employees through an accident arising out of and in the course of the employment, unless the accident is due to intoxication or willful misconduct. No disability indemnity is to be recoverable for the first two weeks of such disability, but after this time has elapsed the indemnity is payable generally on a 65 per cent basis, with fixed maximum and minimum limitations, and for varying periods of time which depend upon the nature of the disability. No contract, rule, or regulation shall exempt the employer from liability for the compensation fixed by the act. Provision is made that the employer may cover the risk of his accidents with insurance companies, which of course is optional, and such insurance is subject to many regulations. Every policy must provide that the insurer shall be directly liable to the employee.

There is also created and established by this act a fund to be known as the 'State Compensation Insurance Fund', to be administered by the Industrial Accident Commission of the state, for the purpose of insuring employers against liability for compensation under this act and insuring to employees and other persons the compensation fixed by the act for employees and their dependents. This fund is to consist of such appropriations as the legislature shall make from time to time, all premiums received for compensation insurance issued, all properties and securities acquired by and through the use of money belonging to this fund, and all interest on deposits or investments. This fund, after a reasonable length of time in which to establish itself as a business, is intended to be fairly competitive with other insurance carriers, and it is expected that it will become self-supporting.

In substance, this system requires in fact, though not in terms, that every employer carry accident insurance for every employee, though farming and housework are excepted. It is expected that the state will furnish this insurance practically at cost and that suitable basal rates will be made for each industry with allowances for lower rates where the conditions of work or the care of the employer reduces the risk. Gold miners feel that they stand in a peculiar situation in this matter, since they can not add the cost of their insurance directly to the price of their product, as is possible in a number of other industries, if not in all. This problem of the gold miner was discussed in the *Mining and Scientific Press* so fully by Mr. A. J. Pillsbury in a series of articles printed in 1912, that we will not go over the ground. It is clear that much will hang upon the construction placed upon the words "wil-

ful misconduct" on the part of an employee, which with intoxication is the sole bar recognized to liability of the employer. Evidently, in any event, nothing remains but to try the system and hope for the best.

News and News

English newspaper proprietors have been engaged in a mock battle with Reuters, the great English news collecting agency. It seems that Reuters places advertisements as well as news, and recently suggested to clients that it had special facilities for securing editorial comment on companies applying to the public for capital. This becoming known, the Newspaper Proprietors' Association waxed indignant, and there was a fine show of wrath. None the less 'reading notices' continue to appear in England, just as they do in the United States, where the laws have recently been tightened up a bit as to this form of misleading the public. We are glad to believe that the sale of editorial and reading space is becoming rare. It is a short sighted policy. The only reason for wishing an advertisement to appear as a bit of news or comment is because of the presumed greater faith that a reader has in the editor than the interested one offering material or shares for sale. The insertion of reading notices, however, destroys that very faith in the editor which is the best asset of any publication.

Plenty of legitimate news comes from those who have something to sell and the news part of what vendors have to say has a legitimate place in news columns. So, too, in our own field, announcements of new types of machinery, of new construction, of changes in plans of operation on the part of manufacturers, all these are of interest and value and are welcomed by the Editor; they are, however, printed in the back of the paper in space reserved for them and every effort is made to discriminate between the claims of the maker, the established facts, and the comment of the Editor, when any is made. Within a year or so an excellent description of a new plant was furnished to the leading mining papers, by the firm that built and equipped it. We printed it with great pleasure in the department reserved for such material. We are told that the editor of one of our contemporaries returned the manuscript with the usual note of regrets, whereupon the manufacturer, who chanced to be an advertiser in the particular paper, sent it to the publisher with a short note asking that it be printed. It was, and in big type. We believe such mixtures of business and editorship will eventually undermine the influence of any paper.

There is only one basis upon which to accept or reject material submitted for publication, and that is its intrinsic worth. Editors are fallible and will make enough mistakes while following that simple rule, and in the inevitable rush of press day or when a holiday in the print shop has upset the schedule, enough unchecked material will slip through. Doing his best, an editor will frequently fail, but for a guiding principle there is none better than that adopted by the *Mining and Scientific Press*, namely, 'tell the truth and make it interesting.'

Lead Salts in Cyanidation

By M. W. VON BERNEWITZ

While the chemistry of the use of lead salts in cyanide treatment has been thoroughly discussed by J. E. Clennell,* less has been written about the practical results of their application. The following notes, compiled from inquiries made from widely scattered millmen and from other sources, are devoted to this phase of the subject.

Uses of Lead Salts

Lead acetate is useful in assaying cyanide solutions, testing roasted ores for sulphur, correcting working solutions of cyanide, and in aiding precipitation. When soluble sulphides are formed by decomposition of certain minerals in ores, or sulphides are present as an impurity in the cyanide salt used, the addition of a determined quantity of lead acetate to mill pulp will convert them into sulphide of lead, which is insoluble and comparatively innocuous. Other salts of lead, such as lead nitrate and litharge, have been used successfully, and their cost is less than the acetate for the unit of lead contained. When the presence of soluble sulphides in an ore, or in the potassium or sodium cyanide used is known, it is well to add lead salts to the ore or the solution at the beginning of experimental work. Soluble sulphides, if not counteracted, will form with the KCN, KCNS, which, though a solvent of gold, is not so active as the free KCN; while the sulphides also absorb oxygen from the solutions. Lead salts retard the formation of this compound, and so when estimating the consumption of cyanide, parallel tests should be made, and the quantity of lead salts necessary to reduce this consumption determined. As an aid to precipitation, J. E. Clennell states in his 'Cyanide Handbook' that when the zinc-lead couple is used, the matter of weak solutions is of less consequence, and very weak ones can generally be precipitated by it. T. L. Carter found that solutions of 0.005 to 0.008% free KCN could be satisfactorily precipitated with 90 to 95% extraction of the gold, using the couple and a drip of strong KCN at the head of boxes. Other workers using the couple have found this drip unnecessary. Occasionally a drip of lead acetate has been used. A 1 to 5% solution on zinc shavings causes an immediate deposit of finely divided lead on the surface of the zinc. This forms a powerful galvanic couple which is capable of depositing gold from solutions of cyanide, much weaker in free KCN than can be precipitated by ordinary zinc shavings. Where copper is present, the couple is often advantageous. W. A. Caldecott has shown that lead acetate acts as a carrier, the eventual result being that the sulphur reacts on the KCN to form KCNS, leaving PbO free for further action. Mexican metallurgists have stated that the amount of lead salt required equals a corresponding amount of sulphur present in solution from the silver sulphide dissolved. Litharge has been used by C. M. Eye to good advantage, instead of lead acetate in treating

reground tailing containing arsenopyrite, pyrrhotite, and the chalcopyrite. Only 1.5 lb. of the former salt was used, against 2.5 lb. of the latter; the litharge cost half as much and showed a saving of 30%. For the purpose of clearer comparison, the consumption and cost of using the corrective agent is shown under the headings of gold ores, silver ores, gold-silver ores, and tellurides.

Gold Ores

The Homestake mine produces a garnetiferous hornblende schist containing 7 to 8% pyrite and pyrrhotite, and averaging \$4 per ton in gold. At the cyanide plants, lead nitrate is preferred to the acetate, and in precipitation it is the practice to maintain a drip of this solution to the feed pipe carrying the emulsion of zinc-dust and cyanide solution; but when the silver content of the solution is above normal, the lead solution is not added. In a clean-up of 2482 lb. of dry precipitate from the Merrill presses, about 212 lb. of lead nitrate has been used.

Ore from the Rand mines may be described as a conglomerate of quartz pebbles cemented by a matrix having a dark bluish appearance when freshly mined. The banket contains up to 87% silica and 2.5% pyrite. According to 'Rand Metallurgical Practice,' before a charge of sand is transferred to the treatment vat, it is sprinkled with a solution of lead acetate. From 15 to 25 lb. dissolved in water is found sufficient to precipitate the soluble sulphides from a charge of 750 tons of current sand. In treatment of slime, previous to transferring pulp in decanting vats, some lead acetate is added for the purpose of converting the ferrous sulphide present into lead sulphide, the former robbing cyanide solution of dissolved oxygen. The quantity of acetate added varies from 5 to 20 lb. per charge of 200 tons. The lead salt is dissolved in water and poured on to the surface of the charge in the collecting vat, so as to be well mixed with the pulp during transfer. In precipitation, all new zinc shaving going to the boxes is dipped in a lead acetate solution, immediately before being arranged in them, as rapid oxidation commences as soon as the couple is formed and exposed to the air. It is also necessary to cover the zinc with solution as rapidly as possible. The use of lead salt in sand and slime treatment not only renders insoluble the soluble sulphides in the ore, but the excess passing through with the solution to the precipitating boxes tends to maintain the efficiency of the couple. The addition of a drip of strong KCN at the head of boxes, originally suggested in this connection, is not generally practised at the present day.

American and Australian Practice

In the Goldfield Consolidated mill, acetate consumption is 0.16 lb. and costs 5.8c. per ton treated, while 2 lb. is used at a cost of 16c. per ton of concentrate treated.

The Black Oak mine, California, yields a hard

**Eng. & Min. Jour.*, September 28, 1912.

silicious ore, and in the all-sliming plant 0.35 lb. of acetate or 0.24 lb. of litharge is used per ton.

At the Sons of Gwalia mine, Western Australia, the ore is a sulphide composed of quartz and schist and containing about 2% pyrite, is practically free milling, and 20% is treated by sand leaching and 80% by slime agitation and vacuum-filtration. Each charge of 170 tons in the sand-collecting vats is sprinkled with a solution of 10 lb. of lead acetate before it is dropped into the treatment vat. Each slime agitator containing 40 tons of solids has 5 lb. of lead acetate dissolved and added to it as soon as full. Until recently a small amount of lead acetate was added to the zinc-boxes, but this has been discontinued as being of no benefit. The quantity used equaled 0.102 lb. and cost 0.8c. per ton of ore milled. The pyrite in this ore oxidizes rapidly, and when sand charges are drained, a small amount of soluble sulphide forms on the top layer. The effect of this is counteracted by the sprinkling of lead acetate. It is very doubtful if the addition to the slime charges is of any benefit in extraction, and it is added to assist in the zinc-box precipitation.

Quartz containing about 1½% of mineral mainly in the form of FeS_2 constitutes the ore from the Great Fingall mine, Western Australia. Acetate is used during agitation in the concentrate treatment; also, when required, it is added at the head of the zinc-boxes. The consumption is about 1 lb., costing about 9c. per ton of product treated (concentrate). The object and result of the use of lead acetate in the concentrate treatment, is the precipitation of soluble sulphides. Its use at the head of the zinc-boxes is to improve the gold precipitation. The quantity of lead acetate used for the purpose is very small, only a few pounds per month, and it is only added immediately after the boxes are newly dressed or at times when the precipitation is bad.

At the Wealth of Nations mill, New Zealand, treating a quartz ore, lead acetate is occasionally used in the zinc-boxes. When precipitation appears to be sluggish, new zinc is dipped into a 10% solution, but the entire amount of lead acetate used in a month does not exceed 2 lb. At the Progress mill, lead acetate has not, in the past, been used, but at the present time experiments are being made, with the following results: Acetate is added to the concentrate pulp in the proportion of 2 lb. per ton of dry concentrate, and the pulp is then agitated for 2 hours before the addition of cyanide solution. At the Blackwater mill, lead acetate is not used.

Silver Ores

The ores at Tonopah, Nevada, may be described as consisting of fine granular quartz (averaging perhaps 80% silica) without noticeable quantities of sulphides, poor in the baser metals, and containing disseminated silver minerals and a little gold. The primary metallic minerals are silver sulphides and the proportion of silver to gold is about 100 to 1 by weight.

At the MacNamara mill it is interesting to note that the charge of acetate may be decreased for a considerable length of time, or even discontinued for a week or ten days, without any noticeable bad effects, there apparently being a process of regen-

eration of some sort from the lead salts thrown down. It has been found by experience that the charge given below is the economical one for this particular ore, this having been determined by actual experiment and not based on any chemical computation. Lead acetate is added to the pulp in agitators at the same time that cyanide is added. The quantity averages from 0.6 to 0.65 lb. per ton of dry ore, and costs 6.5c. per ton treated.

The amount of lead acetate added per ton of ore at the West End mill is 0.5 lb. at a cost of 4.8c. per ton of ore. It is added to the first of the continuous agitators. No difference in extraction can be noted whether none, 0.5, or 1 lb. per ton is added. The plant has been run two weeks without it, but though extraction remained the same, the solutions showed more sulphocyanide. A half pound was considered the correct quantity, because 1 lb. caused a heavy foam on the agitators and did not help the recovery.

At the Montana-Tonopah mill, lead acetate is added to pulp in the agitators. The quantity used is 0.52 lb. and the cost is 5c. per ton treated. General results from its use show a reduced consumption of cyanide.

The Tonopah Belmont Mill

The Tonopah Belmont mill is using about 0.4 lb. of lead acetate per ton of ore, half added at tube-mills and half at agitators, at a cost of 3.6c. per ton of ore treated. Comparative tests show from 3 to 5% better extraction on the silver with 0.4 lb. lead acetate per ton over tests run with identical treatment, but without lead acetate. Between 0.4 and 1 lb. there seems to be but little change in extraction results, although it has been conclusively proved in mill practice that too much lead is worse than none at all. As an example of this condition, it is interesting to note that an agitator charge at the Millers plant failed to go below 50% extraction in the regular agitation period and was circulated to allow more time; on going carefully into the causes it was found that the charge was made up just before midnight and that both 4 o'clock and night-shift men had added the required amount of lead for the charge. Half of this charge was then pumped to another agitator and a half charge of new pulp from collectors added to both agitators without any additional lead; 12 hours' agitation under these conditions showed 80% extraction. The lead added at this plant is governed to a great extent by the amount of zinc in solution. Whenever mill solution shows more than 0.05% zinc, less lead is added, allowing zinc to take care of alkaline sulphides until solutions are again normal, 0.05% zinc or under.

At the Tonopah Extension, lead acetate is added to the agitators when charging. The quantity used is about 0.8 lb. and the cost 8c. per ton treated. It is found that with a silver sulphide ore in cyanide solution, an alkaline sulphide is formed. Alkaline sulphide will precipitate silver out of the solution. By adding lead acetate, or some lead salt, the alkaline sulphide is removed and a lead sulphide is formed which will not precipitate silver from the solution. Formerly about 2 lb. per ton was used, and after 24 or 30 hours samples would show about 90% extraction, or say a residue worth about \$1.20

per ton. A 36-hr. sample might show premature precipitation, and the value would be up to \$1.50 or sometimes \$2. This happened for several days, but with an addition of more lead acetate it was found that there was not only no premature precipitation, but a better extraction. It is also found that, with an excess of lead, the zinc-boxes act much better and give a sump solution with a consistent value. This is especially so with silver ores.

The Nevada Hills mill, Nevada, is treating a silver-bearing ore containing manganese, and the acetate consumed is 0.8 lb. per ton. A complex ore containing 20% silver to 1% gold is treated at El Tigre, Sonora, Mexico, and acetate is added with zinc dust to aid precipitation. In Honduras, Central America, the Rosario mill treats an ore averaging 25 oz. silver and 0.46 oz. gold per ton. About 50 lb. of acetate is added to each Pachuca vat of pulp.

Canadian and Mexican Practice

At Cobalt, Ontario, the high-grade mill of the Nipissing company is treating an ore carrying from 2000 to 4000 oz. silver, 40% arsenic, 6% cobalt, and 6% nickel, and other minerals in small quantities. The ore is ground in cyanide and the silver is amalgamated in a tube-mill, followed by filtration. No lead salts are used, as the mercury in the mill would decompose the soluble sulphides and precipitate a sulphide of mercury.

Ore treated at the El Oro mill, Mexico, is an oxidized quartz, with a small percentage of pyrite, assaying \$8 gold and 3 oz. silver per ton. Lead acetate is placed in a bucket in an agitator to dissolve, using 33 lb. per charge of 100 to 150 tons dry slime. In the same district are the following plants: Mexico Mines of El Oro, the ore of which carries 12 of silver to 1 of gold; lead is added to agitators amounting to 0.25 to 0.5 lb. per ton. Dos Estrellas, at which the ore is a quartz with slightly oxidized iron pyrite, silver occurring as a sulphide with a little chloride, in the proportion of 10 of silver to 1 of gold. In No. 1 mill, the acetate consumption is 0.35 lb. and in No. 2, 0.10 lb. per ton. No. 1 mill of the Esperanza treats a sulphide ore with silver content similar to that at Dos Estrellas, while No. 2 plant treats an oxidized ore. In the former mill, crystals of acetate are scattered over the sand vats, and the consumption is from 0.05 to 0.10 lb. per ton.

At Guanajuato, the Guanajuato Consolidated company produces an ore containing 85% silica, some pyrite, and 187 of silver to 1 of gold. The silver occurs as a sulphide and sulph-antimonide, and the gold is associated with silver sulphide. Acetate consumption is 0.4 lb. per ton. At Pachuca the Real de Monte y Pachuca ore contains 27 of silver to 1 of gold. In the Loretto and Guerrero plants, consumption of lead acetate is about 0.38 lb. at a cost of 6c. per ton. The San Rafael y Anexas ores contain 70 to 75% silica and from 10 to 20% calcite. The silver, mixed with a little pyrite, is found at Ag_2S . Acetate is added to the Pachuca vats, using 0.65 lb. per ton.

Gold-Silver Ores

The Liberty Bell mine, Colorado, produces a hard ore containing 85% silica, 10% calcite, and up to 4% pyrite, the metals of value being gold and silver.

Litharge is added to the tube-mills, where it can be ground. The consumption is 0.3 lb. at a cost of 8.5c. per ton treated. The gold and silver ore from the Standard mine at Bodie, California, is hard, but the numerous veins contain clay seams. Lead acetate consumption is 0.1 lb. and cost is 1.3c. per ton. Ores from the Republic district, Washington, treated in the North Washington Power & Reduction mill, consist of hard quartz with clayey matter containing gold and silver. Lead acetate is used intermittently for one week and then none for about three weeks, this being found to act satisfactorily.

Lead salts are not generally used at the Waihi company's mills, New Zealand, results of its use having been inconclusive. After clean-up, the zinc shaving is dipped into a solution of acetate, and it has a good effect in precipitation. In the treatment of 18,000 tons of ore averaging 60 dwt. silver and 8 dwt. gold per ton, 150 lb. of acetate is used in aiding precipitation on 7280 lb. of zinc shaving. At the Grand Junction mine, in the same district, the ore consists of a gangue of quartz and calcite with pyrite, and $4\frac{1}{2}$ of silver to 1 of gold. Acetate is added to the stamp mortars, where weak solution is used in crushing, while the zinc shaving is dipped in a solution of lead. Consumption averages 0.5 lb. per ton.

Telluride Ores

In general, the ores of Kalgoorlie are of schistose structure, increasing in hardness and silica with depth. They contain pyrite and tellurides of gold and silver, but no minerals harmful to treatment. There is little free gold, it being mainly in the pyrite. The important constituents run up to SiO_2 , 63%; Al_2O_3 , 4%; CaCO_3 , 12%; MgCO_3 , 6%; FeO , 7%; and S, 3.5%. In the roasting plants, alkaline sulphides and thiosulphates are formed with a poor roast, and lead acetate precipitates these, forming insoluble lead sulphides and thiosulphates. In testing the strength of cyanide solutions from agitators by silver nitrate, if enough acetate has not been added at the mixers where the ore and solution first meet, a brown coloration is shown in the test. A solution of acetate is added to the pulp charge until this color does not show any more. As a rule, though, those in charge of the mixing department know when roasts are poor, and act accordingly.

Practice at the Perseverance mill is as follows: lead acetate is mixed in an agitator in 130-lb. lots and run into a lead-lined storage tank. From this it is pumped to a 200-gal. tank and allowed to drip into a mixer with barren cyanide solution, which is used for pulping the incoming roasted ore. The quantity used varies from 0.2 to 0.25 lb. and the cost is 1.35c. per ton of ore treated. The salt has been in use since 1907, and has resulted in an average improvement in gold recovery of 12c. per ton on \$7.20 ore. Acetate is also used as a drip to the zinc boxes, and prevents the gypsum in the roasted ore from precipitating on the zinc.

The lead acetate at the Kalgurli mill is added as a continual stream of solution to the roasted-ore mixer; that is, where the roasted ore and cyanide solution first come in contact. Between 2 and 3 oz. is used, costing approximately 1.2c. per short ton. At the Associated the consumption averages 3 oz.

per ton treated, the lead acetate being added to the roasted ore pulp before it enters the grinding pans.

Treatment at Lake View

The ore treated at the Lake View mill is a schist, containing tellurides and about 6% iron pyrite. Lead acetate is added to the raw-slime agitators in proportion of 1 lb. per charge of 60 tons, and to the roasted concentrate agitators 6 lb. per charge of 24 tons. With the raw slime it is doubtful whether the lead acetate has any effect on the residue, but the presence of the lead salt in solution going to the extractor boxes aids precipitation. With the roasted concentrate the lead acetate acts as a corrective in the event of a bad roast. All fresh zinc, before being placed in the boxes, is dipped in an acetate solution strong enough to just color the zinc. This certainly improves precipitation and the gold slime is more easily washed off the zinc when cleaning up. The total amount of lead acetate used is 0.05 lb. and it costs about 0.4c. per ton treated.

The ore of the Oroya Links mines is a mixture of oxidized and sulphide ores, drawn from orebodies which are of the nature of impregnations of sheared zones. The gold occurs principally in intimate conjunction with pyrite, and also in combination as tellurides. Associated with the gold the following minerals occur, which are likely to cause trouble in the cyanide plant: marcasite, chalcopyrite, fahlerz, tennantite, and stibnite. Lead acetate is added to the agitators to precipitate any soluble sulphides which may be formed by decomposition of the above minerals, or which may be present as an impurity in the cyanide used. The amount found necessary is 0.2 lb. per ton of ore treated. The cost per ton averages 1.6c. of the total tonnage. The zinc shaving used in the zinc boxes reserved for circulating solution is dipped in an approximately 10-oz. solution of lead acetate until it receives a black deposit of metallic lead before being placed in the boxes. This insures a perfect precipitation from solution averaging about 0.04% KCN, and containing gold valued at \$1 per ton. The solution tailing seldom assays more than a trace, less than 6c. per ton.

Stratton's Independence

The experience with lead acetate at Stratton's Independence mill, at Cripple Creek, has been confined to its use in forming the zinc-lead couple in the zinc-boxes. The zinc is cut by hand and dipped in a 3 to 5% solution of lead acetate before using. In the earlier experiments on Cripple Creek sulpho-tellurides the use of lead acetate as added to agitation tests on slime gave rather negative results, and it has not been used in the actual ore treatment since.

The Golden Cycle mill, at Colorado City, is treating about 1000 tons daily of mixed Cripple Creek ores, and about 50 to 100 lb. of acetate is used per day with about 3000 tons of solution. Its use is entirely for precipitating purposes. Acetate solution is fed into the gold-solution storage tanks and it is found absolutely essential for getting steady good results with the zinc, both shavings and zinc-dust (Merrill process). Its use in solution with the pulp to be cyanided has proved to be distinctly deleterious.

Conclusions

It will be seen from these notes that either lead acetate, litharge, or lead nitrate may be used as a corrective agent in counteracting harmful sulphides found in cyaniding various ores, although in treating some ores these salts are negligible. Why acetate should be necessary with Mexican gold-silver ores and of little use with Waihi ores, or of great help in treating Kalgoorlie sulpho-telluride ores and not so with the mixed Cripple Creek ores treated at the Golden Cycle mill, is hard to understand, and it seems to be the general opinion among millmen that lead salts are not always indispensable. It will be found that, in most cases, a solution of lead acetate aids precipitation on zinc shaving. The quantity used on free-milling ores varies greatly. At Tonopah, acetate is found necessary during agitation with the hot cyanide solutions; while at Kalgoorlie the roasted ore pulp is continually fed with a drip of acetate solution, and any variation in roasting is thereby corrected at once. While these notes do not lead to any general rule for the use of lead salts, a millman having similar ores to treat may find something to act as a guide in their use.

In conclusion, I wish to thank the many metallurgists who promptly replied to my inquiries regarding the use of lead acetate in cyanidation, and I hope that the collected data will prove of value.

Resolutions of the Mining Congress

Resolutions passed by the American Mining Congress at the recent session at Philadelphia covered the following points:

1. Favoring passage of state laws to protect minority stockholders and investigation by the Department of Justice of "scandals recently disclosed regarding securities listed on the New York Stock Exchange."
2. Proposing coöperation with the A. I. M. E., the M. & M. Soc. Amer., and kindred organizations in an effort to bring about revision of the mineral land laws of the United States.
3. Providing for appointment of a special committee to study methods of valuing mines for taxation.
4. Suggesting a conference of the heads of statistical bureaus of the United States and the states with a view to introducing uniformity as to form and time of making mining statistical reports.
5. Urging immediate passage by Congress of legislation providing federal assistance to mining schools.
6. Modification of 'anti-trust' laws as applied to natural resources.
7. Urging prompt action permitting development in Alaska.
8. Petitioning for uniform instructions to Collectors of Internal Revenue providing that a definite royalty or depletion charge be allowed in arriving at the net income of mining companies for taxation purposes.
9. Expressing sympathy to relatives and friends of those killed in the Stag Cañon disaster and to the officials of the Company concerned.
10. Urging creation of a Department of Mines.

New Treatment Plants in Rhodesia

By OWEN LETCHER

During the period of modern mining, the gold-fields of Matabeleland and Mashonaland have produced gold valued at over \$120,000,000, and, considering the erratic character of the veins, high transport charges, and, until just recently, woefully wasteful and unsound methods of company flotation and subsequent management, one can only be surprised that the output has been so large.

The New Era

Five years ago only two or three mines in the whole territory followed anything approaching a sane and businesslike development policy. Mills were built without regard to the quantity or value of ore developed. Neither was the mineralogical nature of the ores to be treated studied before the erection of plant, save in one or two instances. The inevitable result of premature crushing, and of milling equipment, generally quite unsuited to the ores, was the closing down of plants all over the country, shortly after the commencement of crushing operations.

At the present, Southern Rhodesia shows signs of considerable progress, and with the much better methods pursued it is probable that there will be a steady increase in output and dividends for the next two or three years. At several of the newer mines of the country a sound policy of development is followed. Thus, at the Shamva, 2,300,000 tons of ore has been developed; and the Cam & Motor property has well over 1,000,000 tons of fairly high-grade ore in reserve. At both of these mines the treatment plants are in course of erection, and it is evident that neither of these concerns can be accused of commencing operations without sufficient ore in reserve. Several other companies have also improved the state of development in their respective mines. Moreover, due regard has been taken of the character of the ores before proceeding with orders for plant. The auriferous deposits of southern Rhodesia vary greatly in both physical and chemical characteristics in different localities. Some ores,

metallurgical method more closely resembling Kal-goorlie than Rand practice. It has, in fact, become realized that more or less standard design treatment plants such as can be employed along the Main Reef Series of the Rand are unsuitable installations to order for southern Rhodesia, and it has been eminently satisfactory to observe at the Cam & Motor,

ERECTING POWER-PLANT AT THE GATOOMA MINE.

and one or two other properties, the employment of small testing plants and diligent study of the requirements of the ores in question before permanent installation has been ordered. There are at the present time either ordered, in course of construction, or just completed, seven different reduction and treatment plants having a combined capacity of about 1,068,400 tons per year. The outstanding features of the equipments in question and estimated yearly capacities are as follows:

Mine.	Locality.	Type of plant.	Yearly capac., tons.
Shamva	Abercorn, Mashonaland	Nissen stamps	550,000
Cam & Motor	Gatooma, Mashonaland	Ball-mills, roasters, tube-mills and slime plant....	180,000
Falcon	Blinkwater, Mashonaland	Nissen stamps, concentrating and sliming plants, blast-furnace, and converters	180,000
Antelope	Southwest Matabeleland	Ball-mills, roasters, and 10 grinding pans.....	48,000
Bell	Jue Jue	Stamps, roasters, and slime plant.....	48,000
Kimberley Reef	Mazoe, Mashonaland	Six Nissen stamps, tube-mill, and sand and slime plants	36,000
New Found Out	Gadzema, Mashonaland	Similar to Cam & Motor.....	26,400

even in depth, are comparatively soft and friable, as for instance the talcose and chloritic schist belts which contain high gold content in some parts of the country. Others again, such as the banded iron-stones, are exceptionally hard. At certain mines the ore is amenable to simple milling and subsequent cyanidation such as done on the Rand, but at others the presence of antimony, copper, pyrite, and arsenic requires roasting plants, and in some instances a

The Shamva's Equipment

Of these plants, that now being erected at the Shamva mine, situated in the Abercorn district, east of Salisbury, with which town the mine has recently been connected by railway, is the most important. The plant was due to start in a month or so, but there have been delays in delivery of material and it is unlikely that the Company will make any real

contribution to this year's output. A considerable proportion of the equipment is now, however, at the property, and the work of erection is proceeding with all despatch. The Shamva ore deposit, which consists in the main of conglomerate, exists in a large *kopje* known as the Lone Star hill. Many advantages will accrue in regard to working costs, as a large tonnage should be mined and delivered to the reduction works through adit-levels at small cost. Ore will be transported through the adits by means of petrol locomotives and dumped into a large storage-bin. From this it will be fed into ears and lowered by gravity to grizzlies built over three No. 7½ Gates crushers. After the oversize has been reduced in these, the whole product, fine and coarse, will be carried by a belt-conveyor to the trolleys. In these the ¼-in. mesh product will be eliminated and sent direct to the tube-mills, while the oversize will be discharged into the mill ore-bin. This latter will feed 56 Nissen stamps, each of 2000 lb. weight when new, and using ¼-in. mesh screens. The intention is to crush the ore in cyanide solution. After leaving the mortar-boxes, the pulp will gravitate to the feed cones of eight 22-ft. tube-mills, fitted with Osborne liners. The underflow from these cones will pass through the tube-mills over short copper plates and blanket tables, and thence to a centrifugal pump to be elevated to the cones again. The overflow of the tube-mill cones will pass direct to eight sand cones superimposed over four others in which the sand will be removed, and, mixing with the barren solution from the slime plant zinc-boxes, will gravitate to eight 50-ft. by 8 ft. 6-in. sand-collecting and leaching tanks in which the sand will be leached, washed, and afterward dumped by endless-rope haulage in the usual way.

Overflow from the Cones

Slime and solution overflowing from the sand-cones will go to five 35 by 10-ft. Dorr thickening vats, part of the clear overflow of which will run to the zinc-boxes, and a portion back to the mill supply-tank.

The thickened pulp from the discharge of the Dorr vats will be pumped to five 45 by 10-ft. Pachuca agitators connected in series, where, after air agitation, the slime will run to the storage agitators connected with a Butters filter-plant. The latter will contain 336 leaves and has been designed for the gravity system of working. All solutions will be precipitated in ordinary zinc-boxes, and the gold melted in two Morgan gas-fired furnaces. Water-supply for the mine will be drawn from the Inyagui river, and pumped by means of an electrically-driven three-throw pump, through eight miles of 12-in. pipe. In the table of milling capacities appearing in the early part of this article, the tonnage, which it is expected will be treated monthly at the Shamva, is given as 45,000 tons, but in actual practice it is probable that this will be exceeded. It will be noticed that there will be one tube-mill to every seven stamps, an even higher proportion of tube-mills than at the Consolidated Langlaagte or the Van Ryn Deep on the Rand. Should a capacity of 50,000 tons per month be obtained, the stamp-duty would be in the neighborhood of 35 tons per

head per day. In any case, it looks as if the Shamva will establish a world's record in the matter of duty for gravity stamps.

Other Experiments

The Shamva is under the control of the Goldfields Rhodesian Development Co., as are also the Antelope and the Bell mines. The two latter properties are expected to reach the producing stage this year. The Faleon, which is a gold-copper property, is unlikely to become productive before some months have elapsed, but the Kimberley Reefs plant is already working. As to the Cam & Motor, the rock-crushers are in position, all brick and iron work for the drying plant completed, and a large part of the ball-mill installation finished. The six Edwards roasting furnaces are practically ready for work, and all the steelwork for the precipitation, clean-up, and filter plant was erected some time ago.

With regard to the Antelope, which is situated in a particularly dry and arid part of Matabeleland, construction work on the dry-crushing plant is understood to be progressing satisfactorily. Metallurgists in Rhodesia are eagerly awaiting the starting of these new plants, and the comparative results secured will be noted with the greatest interest. It is not too much to say that the erection of these large mills signalizes the dawn of a new mining era in Rhodesia.

A process is now being used in Germany whereby steel is hardened by means of compressed air in cases where only certain parts of the metal require hardening. The customary methods of hardening by chilling the steel in water, oil, or special baths is not satisfactory in such cases, owing to the tension created between the hardened and unhardened portions of the treated metal. In the new process the compressed air is sprayed over the metal through specially designed nozzles, by means of which, by varying the number and spacing of the openings, the degree of hardness may be accurately regulated.

Freshly-ignited charcoal is a recognized precipitant of gold in cyanide solutions, while graphite, according to Morris Green, does not precipitate gold. The action of graphite has been the subject of considerable discussion during the last few years, and, on the whole, remarkably little experimental evidence has been adduced either to prove or disprove any contention. On the other hand, experience at Kalgoorlie has shown that the graphitic slate or schist in certain mines unmistakably precipitates gold from solutions in the mills.

Taxes in an operating company should be charged to operations, never to property, according to J. B. L. Hornblower. The amount of tax chargeable to the operation of a given mine ought to be, as nearly as may be, the tax upon the ground which will ultimately be operated through that mine, and the tax for a given year should be apportioned in equal amounts over the divisions of the year for which cost statements are made.

The present price of radium is \$2,300,000 an ounce.

The Rand Banket—Part V

By C. B. HORWOOD

Particular Series Selected by the Solutions

It has already been shown that the numerous beds of conglomerate in the Witwatersrand system can be grouped into eight principal series;¹⁸⁸ three in the Lower and five in the Upper division of this system. Of the former, the Promise reef is the lowest, and is narrow, small-pebbled, and ill defined. The Coronation reef, 2750 ft. above it,¹⁸⁹ is a rather more prominent lode, but is also small-pebbled. These two series are unprofitable, and usually contain little more than traces of gold, or none at all. The Government reef, 1900 ft. above the Coronation,¹⁹⁰ is in places well defined; it consists generally of three or more beds of conglomerate; there is usually one main bed, sometimes as much as 2 ft. thick, overlain by two or three small leaders separated from it, and from each other, by intervening quartzite. Here and there it contains an encouraging amount of gold; consequently, considerable prospecting work has been done on it, but no really successful mining operations have resulted. Between this banket series and the lowest of the five in the upper series, broad persistent bands of shale, many hundreds of feet thick, intervene.¹⁹¹

The Bird and Livingstone Series

Of these five series, the Bird and Livingstone are the smallest and usually contain only traces of gold, insufficient to have encouraged prospecting. The remaining three are big and well defined, each containing several prominent conglomerate beds and leaders. The biggest of the three, and the one that

throughout contains the largest pebbles, is the Elsburg series, in which a little gold is sometimes found, but not enough to have attracted much attention. As it consists of big-pebbled, wide conglomerate beds, it would have offered easy access to any mineralizer; and the reason it was not chosen for the main arteries of circulation can be explained by the fact that the up-rising solutions had already encountered the Main Reef series, more than 11,000 ft. lower in geological horizon.¹⁹² Over 6000 ft. below the Elsburg is the Kimberley series, which, though not quite so big as the Elsburg, is a prominent group consisting of numerous large-pebbled beds and leaders. It lies about 5000 ft. above the Main Reef series and is a much larger group; its conglomerate beds are composed of bigger pebbles than the two, relatively, poorly defined Bird and Livingstone series, which lies between it and the Main Reef beds. Thus, it has been more largely favored by mineralizing solutions than the other series already described. Assays of 2 to 3 dwt. per ton can frequently be obtained; and, in places, on the Far West Rand it has been profitably mined.

The Main Reef

The series, however, that was selected by the solutions, in lieu of fissures, for channels of maximum circulation in which to deposit their mineral contents, is the one known as the Main Reef. In the Lower beds three series had already been encountered; the first two contain small pebbles and are poorly defined; consequently, they contain little gold; the next is better defined, but only poorly when compared¹⁹³ with the Main Reef conglomerates; it contains some gold, though not in profitable quantity. After these three, the solutions in their upward course reached the Main Reef series, which, being in a higher geological horizon, was more porous. Further, and of chief importance, it was a well defined and well pebbled series occurring a short distance above broad persistent bands of shale that acted as an impervious layer on the foot-wall side of the channels. The great influence of underlying impervious strata, in the form of shale, is shown in a remarkable manner by the fact that, broadly speaking, the only other two series besides the Main Reef on which any considerable work has been done are the Government and Kimberley series, and these are the only others that are underlain by shales;¹⁹⁴ and of these two the only one on which profitable mining has been possible is the Kimberley, the higher of the two in the geological column, and immediately overlying a

¹⁸⁸The strip of beds of conglomerate at Rietfontein, known as the Du Preez series, which have been proved for some two miles along their strike, are not included in the above, as their particular geological horizon is still in doubt. It is contended by many that they are a faulted portion of one or other of the above eight series.

¹⁸⁹As shown in Mellor's composite, or normal, section of the Lower Witwatersrand system for the Central Rand. In his section through Witpoortje, on the West Rand, the distance between these reefs is about 1000 ft. less. 'The Normal Section of the Lower Witwatersrand System, etc,' by E. T. Mellor, *Trans. Geol. Soc. So. Af., Vol. XIV (1911), plate XVII.*

¹⁹⁰As shown in Mellor's normal section for the Central Rand. In his Witpoortje section the distance is about 750 ft. E. T. Mellor, *loc. cit.*

¹⁹¹The probable aggregate thickness from the Government beds to the top of the shales underlying the coarse quartzites (125 to 400 ft. thick), locally known as the 'Red Bar' (which is immediately below the Main Reef) is 3700 ft. at Florida and Hamburg on the near West Rand; and 2000 ft. at Witpoortje. Although soft quartzitic sandstones and sandy beds alternate with slaty shales and shaly beds, the two latter account for the greater part of these thicknesses. See Mellor, *loc. cit.*, p. 129.

At Randfontein, the section from the West reef (which corresponds to the Main reef of the Central Rand) downward to the Government reef consists of 350 ft. of quartzites and sandstones with occasional bastard (or poorly developed) bankets, and diabase intrusions; followed by 540 ft. of 'foot-wall' shales; and, then some 3200 ft. of quartzites and sandstones with occasional shale bands and diabase intrusions.

¹⁹²The distance is calculated from the section by Truscott, 'The Witwatersrand Goldfields, etc.,' by S. J. Truscott, Macmillan & Co. (1902), Chap. 3, Fig. 1.

¹⁹³This is especially so when followed over any great distance along the strike.

¹⁹⁴Neglecting the Promise reef, which is underlain by shales; but is a poor ill-defined banket near the base of the system.

thick, well defined band of shale known as the Kimberley Shales. The conglomerates have not such well defined or impervious walls as normal fissure-veins, and consequently the retaining influence of the shale has been particularly effective in confining the solutions to the main channels of circulation to the extent that the gold as deposited, was concentrated in those channels instead of the same amount being more widely distributed, and consequently being more difficult, sometimes impossible, to mine at a profit.

Extension Along the Strike

Only those who are personally acquainted with the Rand can fully appreciate the extent of this great goldfield, which produces about 38% of the world's annual output of gold.¹⁹⁵ At the end of the year 1912¹⁹⁶ the ore reserves for 50 of its mines amounted to over 87,000,000 tons. If the annual rate of crushing be taken at 27,000,000 tons, these figures show that these reserves are more than three years ahead of the stamp-batteries.¹⁹⁷

The assay-values of the conglomerates that are mined vary, often within a distance of a few feet¹⁹⁸ between wide limits from a trace to several hundred pennyweights per ton;¹⁹⁹ yet fairly regular alternations between relatively rich and poor stretches of ground occur along the strike; further, it is a remarkable fact that over large areas (up to, say, one to three thousand feet, and frequently more) along the strike, the average yield is remarkably constant. Largely it is this fact that has, in the past, made the Rand such a particularly attractive field for the capitalist. The total recoverable gold contents of a given undeveloped mining area can usually, from various available evidence,²⁰⁰ be estimated with a sufficient degree of accuracy to warrant the enormous expenditure required to sink shafts; to do the necessary amount of development; to erect the costly treatment-plant necessary to deal with large tonnages, and houses and other buildings.²⁰¹ This expenditure can be made with the

conviction that the gold eventually to be recovered will suffice to redeem all the capital outlay and to give in addition at least a fair rate of interest on this capital during the life of the mine. In fact, the conditions are comparable not with those of ordinary gold-mining with which one is accustomed when dealing with quartz veins, but rather with those obtaining in the case of coal properties,²⁰² when usually the total coal contents, life, and profit per ton can be estimated with reasonable accuracy while the ground is still virgin; and therefore the expenditure of large sums of money at this stage, to exploit the property, is justified.²⁰³

Outcrop of the Main Reef

The actual outcrop of the Main Reef series can be traced at the surface almost continuously from the southern extremity of the farm Randfontein on the Far West Rand to the farm Modderfontein on the Far East Rand,²⁰⁴ with the exception, just east of Boksburg, of a stretch of some four miles where it is covered by the coal measures. This represents a distance of over 40 miles, as the crow flies, and of over 55 miles as measured along the strike. The town of Johannesburg is situated midway between these limits. Beyond the eastern limit the outcrop dips below the Black Reef and Dolomite formations; but the sub-outcrop, sweeping round and striking southeast, has been traced by bore-

Brodigan, lecture delivered on Jan. 27, 1913, before the Royal School of Mines Union.

²⁰²Except that in estimating the probable profit obtainable, one is dealing in the case of the Rand with a final product for which there is always an assured market at a fixed price.

²⁰³In the management of a Rand gold mine, administrative ability is as essential as technical knowledge and skill. Apart from the difference in the actual material of the outputs in the two cases, Rand gold mining may be looked upon as a sort of glorified coal mining. It has taken long for this to be as fully recognized as it might have been in relation to actual underground mining operations. It is only within the last three or four years that colliery methods, modified where need be to suit local conditions, have been introduced underground. Their introduction has been the means of more efficiently and cheaply handling large tonnages of ore. The introduction of these methods has been mainly due to the initiative and determination of Henry Stuart Martin, consulting engineer to Messrs. F. Eckstein & Co.

However, in one important respect Rand mining differs from colliery work and approximates somewhat to quartz mining in the fact that for the best results an intimate knowledge of the 'reefs,' coupled with close underground supervision, is essential otherwise small, often insignificant leaders that should be mined are left behind. This has, for example, sometimes occurred in the case of the South Reef Leader on the West Rand. There this leader is a small seam, varying from merely a single line of pebbles up to 3 or 4 in. thick, yet it is the principal gold-carrier of the South Reef series, without which the rest would be unprofitable. When, as has happened, through careless mining, it is left behind in the foot-wall of the stopes, the rock from these stopes is unprofitable and the grade of the mine is thereby lowered, the gold recovered for the month is less; and the profit is reduced. When gold is left behind in the stopes, it is generally lost for good, as it is the exception for the mistake to be discovered and rectified.

²⁰⁴Immediately to the east of the farm Modderfontein is the farm Geduld, on which are situated the Geduld Proprietary mines. These are the farthest east of all the mines that have as yet reached the producing stage. The lode does not outcrop on this farm, the Witwatersrand beds

¹⁹⁵*The Mining Magazine*, Oct. 1912, 'Rand Problems,' p. 248.

¹⁹⁶Where figures for that date were not available the statistics were obtained from the last published annual reports. *South African Min. Jour.*, May 24 (1913), p. 311.

¹⁹⁷If to this be added the ore partly developed or partly valued the great bulk of which may be assumed to be profitable; and, also the profitable reserves in a few of the mines not included in the above, a grand total of about 110 million tons is obtained. *South African Min. Jour.*, May 24 (1913), p. 311.

¹⁹⁸In sampling the drives the samples are usually taken at 5-ft. intervals; and variations in assay such as stated above often occur within these distances.

¹⁹⁹On the Rand the ton used is the short ton of 2000 pounds.

²⁰⁰Such as is, for example, obtainable from general experience on the Rand, the value of adjacent properties, outcrop yield, and to some slight extent from boring results.

²⁰¹To bring an ordinary Rand 'deep,' or second-row 'deep-level,' to the producing stage usually necessitates the expenditure of from about $\frac{1}{2}$ to $1\frac{1}{4}$ million pounds sterling, according to circumstances.

For example, C. B. Brodigan states that the first sod of the Brakpan mines was cut on May 24, 1905, and the battery started on the same date six years afterward. During this period approximately £1,250,000 had been spent on the property. 'Rand Practice in Deep Shaft-Sinking,' by C. D.

holes for another 10 or 12 miles. On the Far West Rand also, to the south of Randfontein, the outcrop disappears beneath the Black Reef and Dolomite formations; but, 7 or 8 miles to the southwest, conglomerates claimed to be those of the Main Reef series have been encountered in bore-holes on the farm Gembokfontein. Whether these latter belong to the Main Reef series or not, the outcrop, or sub-outcrop, has now been traced for a distance of nearly 70 miles. Further, on the Far East Rand there can be no reasonable doubt that the sub-outcrop continues from the farm Palmietkuil and joins with what is known as the Nigel Reef,²⁰⁵ which outcrops 10 miles farther south, and on which the Nigel mine has worked profitably for many years past. Thus the outcrop, or sub-outcrop, of the Main Reef series is known for a total distance of nearly 80 miles. From Randfontein to the eastern boundary of Modderfontein, a distance of over 55 miles, with the exception of two breaks in faulted and disturbed ground,²⁰⁶ there is one continuous chain of mines. With only about half a dozen exceptions, these mines are being profitably worked, and it is a significant fact that the mines at both the present western and eastern limits of this goldfield are good.²⁰⁷

Magnitude of the Goldfield

There is no other known goldfield where the outcrop of a lode has been traced for such a long way and has proved profitable for practically the whole distance. It should be remembered that these mines, with few exceptions, work two separate parallel lodes.²⁰⁸ What is regarded on the Rand as a single mine actually consists of two mines, situated side by side, separated by some 60 to 200 ft. of country rock²⁰⁹ and connected with each other by cross-cuts. The unrivaled magnitude of this goldfield can be better realized if one tries to imagine this stretch of some 50 miles of twin mines pulled out tandem fashion into one long continuous line of single mines extending for over 100 miles along the strike; and then also realizes that these outcrop, or sub-outcrop, mines are succeeded by a series of neighboring and parallel deep-level mines.

The agencies that brought about such unusually extensive gold deposition, from which already, in 26 years, £347,000,000 worth of gold has been recovered, must have had a vast store of precious metal upon which to draw. It is difficult to imagine

being covered unconformably by the Dolomite formation and Karroo beds.

²⁰⁵See 'The Extension of the Witwatersrand Beds Eastwards under the Dolomite, etc.,' by F. H. Hatch. *Trans. Geol. Soc. So. Af.*, Vol. VII, part 2 (1904).

²⁰⁶One of these is on the West Rand, where there is a stretch of broken ground extending for about 2½ miles between the Princess Estate and the French Rand mines. The other stretches for 3 to 4 miles between the New Blue Sky and Apex mines on the East Rand.

²⁰⁷That is, those working on the southern portion of the lode (just before it disappears) on the far West Rand and the working mines on the extreme far East Rand.

²⁰⁸They work the two sub-series known as the Main Reef series proper, and the South Reef conglomerates.

²⁰⁹This term is used because it has crept into general use. To employ it is, however, to be guilty of tautology, as the simple term 'country' signifies the rock surrounding or enclosing a lode (see Le Neve Foster, *loc. cit.*, p. 10).

one sufficiently adequate to account for such a concentrated occurrence of gold other than the igneous rocks and their source, namely, the underlying molten magma with which in depth they are connected.²¹⁰ These rocks are well represented throughout the mines on the Rand by ancient decomposed and uralitized, longitudinal, diabase dikes. Later it will be shown that in type and chemical composition these closely resemble the Klipriviersberg diabase of the Ventersdorp system, and, as has already been shown in the early part of this paper, the main structural features of the Witwatersrand clearly point to both having originated from a common magma.

Persistence in Depth

As in all deposits from mineral solution (either liquid or gaseous) that have ascended directly from great depth, or that have been given off as hot primitive solutions by cooling igneous intrusions, a fall in the grade of the ore with depth is to be expected.²¹¹ This is the natural consequence of reduction of temperature and pressure as the solutions ascended nearer to what was then the surface. The laws governing such cases are well known and well understood.²¹² In June 1905²¹³ the writer stated that "it is found that the average gold values of the Main Reef series for the whole of the Witwatersrand decrease slightly in depth." In illustration of this, he showed that the average yield in fine gold for the whole of the Witwatersrand for the year 1890 was 11.63 dwt. per ton, and for 1904, 9.08 dwt.; and that the average yield per year for the 6 years 1890 to 1895, inclusive, was 10.95 dwt. per ton; while for the 6 years 1896 to 1904, inclusive (omitting the war period, 1899-1901), it had fallen to 9.47 dwt. per ton. For 1912 the average gold recovery was only 29 shillings, or about 7 dwt. The following figures clearly show how the grade has steadily fallen.²¹⁴

STATEMENT TO SHOW THE GRADUAL FALL IN GRADE

Year.	Tons milled.	Oz. fine gold.	Dwt. per ton.
1887	Not recorded	19,296*
1888	Probably about	173,741*
1889	700,000	309,646*

²¹⁰J. F. Kemp has pointed out that "the presence of even a very small dike in any region is proof of the existence of a relatively very large reservoir of igneous rock, at some point beneath the surface, and at unknown but not great depth." 'The Role of the Igneous Rocks in the Formation of Veins,' by J. F. Kemp, in 'The Genesis of Ore-Deposits,' 2nd ed. (1902), pp. 681-709. The reader is particularly recommended to study this treatise in connection with the above argument.

*Approximate.

In studying these results, it must be borne in mind that the higher yield obtained during, say, the first eight or nine years was due to work being mainly confined to the rich oxidized ore above the ground-water level.²¹⁵ Prior to the year 1904 the total tonnage milled was comparatively small, the working cost, in consequence, was relatively high, and therefore ore that can be profitably mined to-day had then to be rejected. From 1904 onward, the amount of ore treated annually has rapidly increased; in consequence, the cost per ton milled has diminished and lower-grade rock has continually been extracted, the average grade having been thereby reduced. The progressive drop in the yield from the ore milled is thus by no means entirely due to the decrease in richness with depth. A very satisfactory feature is the steadiness of the grade for the last four years. That for 1912 is slightly higher than that for 1909,²¹⁶ in spite of the fact that about 5,000,000 tons more was crushed in the former year than in the latter. Certainly a much larger proportion of low-grade ore is now mined, that formerly, owing to higher working costs, would have been left behind; and it is becoming increasingly necessary to be able to mine profitably rock of lower grade, because otherwise large areas of deep-level ground would not be worked at all.²¹⁷ This is being done with great success; for example, in the lower remaining portion of the Glencairn mine,²¹⁸ rock yielding about 3½ dwt., at the Knight's Deep²¹⁹ of about 3½ dwt., and at the Jupiter²²⁰ mine

²¹⁵The oxidized zone extends to about 300 ft. below the surface.

²¹⁶This is probably partly due to the good grade of some of the far East Rand mines that have entered the producing stage since 1909.

²¹⁷H. H. Webb in his 1910 report to the Consolidated Gold Fields of South Africa, stated his opinion that "about 5 dwt. is a grade which will eventually represent an average over a large area of the Rand, especially in the deeper sections."

²¹⁸The poverty of the Glencairn mine is partly due to the fact that wide bodies of low-grade hanging-wall banket are being worked.

²¹⁹See annual report for year ended July 31, 1912. The waste sorted equalled 3.1%. In their report for the quarter ended April 30 (1913) the directors of the Knight's Deep point out that during the first 6 months of the combined

of 5 dwt., or less, is now being worked at a profit. The ore reserve of the Knight's Deep mine at July 31, 1912, was given as 1,477,000 milling tons,²²¹ having an assay-value of 4.7 dwt., and some 46,000 tons partly developed of an estimated value of 4.3 dwt.; and those of the Jupiter at December 31, 1911, as 1,089,000 mine tons of 5.4 dwt. ore, and some 245,000 tons partly developed of an indicated value of 5.2 dwt.; in addition, there was some 230,000 tons developed, valued at between 4 and 4.5 dwt. per ton, which the consulting engineer, C. D. Leslie,²²² stated in his report was excluded from the ore reserve until such reductions in working cost are effected as will warrant their inclusion.²²⁰

Placer Deposits

If the auriferous bankets are placer deposits, then, as De Launay²²³ pointed out, one would expect a reduction in grade as distance from the original shore-line was attained. A gradual decrease in the gold tenor with depth is only natural if the bankets represent lodes that have been mineralized by ascending deep-seated solutions (either liquid or gaseous), and, as will be shown, is in this case no cause for alarm. Against the fall in grade with depth, is the important fact that several mines are now working at a profit on low-grade ore yielding about 5 dwt. and even less, and that the working costs at several mines, including these, only average about 13s. 6d. per ton. F. H. Hatch²²⁴ has pointed out that "working at a cost of 13.8 shillings per ton means that the cost of development, extraction, and reduction, including administration, is covered by a recovery of 3¼ dwt. of fine gold per ton. On 5-dwt. ore, therefore, this would allow a profit of nearly 7s. 6d. per ton. And it is only necessary to look at the value of the ore reserves of many of the big mines given in the latest published official reports to see that this is not far from the average grade of much of the ore which the controlling engineers propose to work in the near future." As the writer

working of this mine with the Simmer & Jack East, 631,630 tons of ore, yielding 15s. 1d. per ton, was crushed, giving a profit of 4s. 1d. per ton, or a total working profit of £129,084. The *Financial Times*, June 28 (1913). For the month of April (1913) the full battery of 400 heavy stamps plus 9 tube-mills were at work; and 104,800 tons was crushed. No sorting was done and the total recovery was at the rate of 3½ dwt. per ton. The working cost was 10s. 8d. per ton; and the working profit was £23,039. *South African Min. Jour.*, May 31 (1913), p. 335.

²²⁰See annual report for year ended December 31, 1911. The waste sorted equalled 9.5%. A notice appeared in the *Financial Times* for April 30 (1913), stating that the directors had decided to increase the capacity of the Jupiter treatment plant up to 60,000 tons per month "whereby it is anticipated that working costs will be reduced to a figure which will enable the ore of a mine grade of 4.1 dwt. to be treated profitably."

²²¹See annual report.

²²²C. D. Leslie, who is consulting engineer to the Consolidated Gold Fields of South Africa, has played a large part in bringing about low working costs, as the costs of the deep-level mines under his technical administration testify. His success in this direction is in great measure due to his making fuller and more efficient use of small stoping machines in place of hand-labor.

²²³De Launay (1903), *op. cit.*

²²⁴"The Past, Present, and Future of the Gold Mining Industry of the Witwatersrand, Transvaal," *loc. cit.*

has already pointed out (in Part IV of this paper), the amount of gold still to be profitably extracted down to a vertical depth of 5500 ft. below the blanket outcrops will probably be twice the amount that has been won up to the present time; so there can be no doubt about the greatness of the Rand as a gold-producer for many years to come. Each year the Rand is developing, more and more, into an enormous, well managed, low-grade goldfield, which, with increasing tonnages milled, steadily decreasing costs, and simultaneous lengthening of its life by the inclusion of still lower-grade ore within the economic limit, is still increasing its annual output of gold, probably reaching a value, for the current year, of £40,000,000.²²⁵

Secondary Enrichment

As is usual in normal gold-quartz veins, so also in the blanket, there is abundant evidence all along the Rand of secondary enrichment in the oxidized zone, and often for some distance below it. The limit of the oxidized zone is passed at a depth of about 300 ft., and, speaking generally for the whole Rand, it has long ago been exhausted. Hence no allowance need be made for this upper area when considering the fall of grade with deep mining. Neglecting the oxidized zone, and any secondarily enriched portions extending below it, the deep-level ground is not so rich as that worked by the outcrop mines. There are numerous good examples of this, but it would be invidious to quote them while the mines are still being worked. The economic limit of normal gold-quartz veins can usually be represented by sections²²⁶ resembling that of an inverted cone; these are often somewhat 'squat';²²⁷ frequently, they approach equilateral shapes; and are seldom greatly elongated in comparison with the inverted bases (or outcrops). Cracks, or fissures, starting at the earth's circumference or surface and gradually, as the rocks in depth become more compact, dying out toward its centre,²²⁸ would assume similar shapes. It would thus appear that up-rising solutions gain admission in depth to fissures through

minute channels of slight lateral²²⁹ extension. As the surface is approached, the fissures become less 'tight'²³⁰ and the solutions, in ascending, spread out more and more on either side along the fissures. In the case under consideration the function of the fissures has been performed by big well defined beds of conglomerate, which have necessarily differed from the former inasmuch as they have formed porous channels for their full length down to a great depth, the immediately underlying and overlying strata (corresponding to the foot and hanging walls of normal cracks or fissures) having been kept apart by the intervening pebble-beds. Thus instead of the profitable zone tapering downward to an apex, the gold contents should in depth extend for the same distance along the strike as at the outcrop, and experience in this case shows that they do. The deepest workings of the deepest mine on the Rand are well over 5000 ft., or about one mile vertically below the surface.²³¹ This mine, although situated in what is recognized as a poor area, is being worked at a profit. With low working costs, the aid of electricity, and other recent improvements for stage-hoisting, with good ventilation to compensate for the slowly increasing temperature, profitable mining will doubtless be extended far beyond this vertical depth. Later it will be shown that these auriferous conglomerates may be considered as a special type of lode deposit, and that they owe the deposition of their iron sulphide and gold and their final cementation by secondary silica to neighboring igneous intrusions and the underlying magma from which the latter originated; consequently, the mineralization should continue downward toward their intersection with the main mass of igneous rock to which their mineral contents are due.²³² It will presently be shown that the available evidence indicates that the latter is represented by the Ventersdorp diabase. The intersection of the blankets with this diabase, and the extent of their mineralization in depth, will doubtless be far beyond the limit to which man is likely to penetrate.

Distribution Within the Main Reef Series

The most typical development of the Main Reef series proper is usually considered to be along the central portion of the Rand. From below upward this series can be divided into two sub-series consisting of an underlying Main Reef series proper

²²⁵Since the above was written a general strike of the white miners on the Rand occurred early in July (1913). Although it only lasted for a few days, yet the unsettled state of affairs that existed for some time both before and after, and its effect on white labor, together with the temporary cessation of native recruiting, will result in this figure not being reached this year; but last year's record of £37,182,795 will probably be exceeded by approximately one million sterling.

²²⁶Either vertical sections or sections on the plane of the blanket.

²²⁷Compare J. H. Curle, *loc. cit.*, p. 45, where he states his opinion, with which in general the present writer entirely agrees, that "a pay-shoot is liable to extend farther in length than in depth."

²²⁸Research work indicates that openings cannot exist at greater depth than about 30,000 ft.; and under certain conditions very much less. 'Ore Deposition and Vein Enrichment by Ascending Hot Waters,' by W. H. Weed. *Trans. Am. Inst. Min. Eng.*, Vol. XXXIII (1903), p. 750.

Also, 'On the Limiting Strength of Rocks Under Conditions of Stress Existing in the Earth's Interior,' by Frank D. Adams, *Jour. Geol.*, Vol. XX, No. 2.

And, 'Some Principles Controlling the Deposition of Ores,' by C. R. Van Hise in 'The Genesis of Ore Deposits,' 2nd ed. (1902), pp. 286-288.

²²⁹The term 'lateral' is here used to denote distance along the strike.

²³⁰That is, their walls are not in quite such intimate contact; and the fissures are consequently somewhat more open.

²³¹A. E. Pettit, resident engineer in London to the Consolidated Gold Fields of South Africa, informed the writer that at the end of the year 1912, the deepest workings in the Jupiter mine were 5040 ft. vertically below the surface.

²³²See 'Ore Deposits near Igneous Contacts,' by W. H. Weed, *Trans. Am. Inst. Min. Eng.*, Vol. XXXIII (1903), pp. 744-746. The mineralization should continue downward to the intersection of the deposits with the main mass of igneous rock to which they owe their pyrite and gold, provided always that this intersection is not below the zone of precipitation. If it is, the solutions in their upward course below this zone would have been under sufficient temperature and pressure to have retained in solution their mineral contents. See W. H. Weed (1903), *loc. cit.*, p. 553.

and an overlying South Reef series. The former consists of the Main Reef itself and an overlying Main Reef Leader. The Main Reef is a big body of low-grade conglomerate, assaying from about 2 to 4 dwt. per ton, and usually 4 to 12 ft. thick. The Leader is a thin but rich seam of conglomerate, often only 3 to 4 in. but sometimes as much as 2 ft. or more thick, containing quartz pebbles up to 2 and even 4 in. or more in diameter. Usually separated from the Main Reef by a thin close-grained almost impervious band of shale 3 to 8 in. thick, but occasionally also by 5 ft. or more of quartzite, it is the profitable member of this sub-series; and, where developed, is the principal gold-carrier of the whole Main Reef series. At a distance varying from 40

thick, which is of little value and for the most part is left behind, and is not included in the stoping width.

As already stated, the mineralization of the conglomerate has practically been confined to the lowest²³³ of the three series lying between the Kimberley slates and the Main Reef foot-wall slates. The concentration of the gold has been principally confined, in the upper subdivision of this series, to its lowest leader, which rests on a somewhat sericitic schistose foot-wall; and in the lower subdivision to its upper leader, instead of the lower main body. The latter circumstance appears curious until it is realized that this upper leader is usually immediately underlain by an almost impervious band of

FIG. 23.

to 120 ft. or more above this is the other subdivision, known as the South Reef series, consisting typically of a thin foot-wall seam of conglomerate, varying from a single line of pebbles (which are occasionally as much as a foot apart) up to a band 5 or 6 in. thick. The matrix of this leader and its overlying quartzite is usually black, compact, crystalline, and sharply defined from the softer light-gray quartzite on which it rests and which is usually somewhat sericitic and often exhibits a tendency to a schistose structure. This foot-wall leader is known as the South Reef Leader. Generally containing the biggest pebbles, and the average size of its pebbles as a rule being greater than those of the other bankets of this subdivision, being also the lowest leader of the sub-series and usually resting on a somewhat sericitic foot-wall, it contains nearly all the gold, and so constitutes the richest member of this sub-series. Its gold contents are, however, much more erratic than those of the Main Reef Leader. About 8 in. above is the Middle Leader, which is 6 to 10 in. thick; this usually contains a few pennyweights of gold per ton and is stoped with the South Reef Leader. About 12 in. or so above this Middle Reef is the Hanging Wall Reef, often about 10 or 12 in.

shale; and, in addition, it is the biggest-pebbled conglomerate of the whole series.²³⁴

Distribution of Gold Between the Main and South Reef Series

It has just been stated that the gold in the Main Reef series proper has been principally concentrated in two small leaders, one at the top of the lower sub-series, the other at the bottom of the upper sub-series. Practical experience from end to end of the Rand has indicated that when one of these leaders is poor that portion of the other leader (in the other sub-series) opposite to it is often rich, and *vice versa*; or, in the words of the miner, "the values have gone from the one reef to the other." This

²³³That is, the Main Reef series.
²³⁴and consequently would have been more porous per unit-area of cross-section. The reader is referred to the discussion on J. W. Gregory's paper, "The Origin of the Gold in the Rand Banket," by J. Malcolm MacLaren, who shows by clear reasoning that the conglomerates were undoubtedly more permeable than the sandstones and quartzites. *Trans. Inst. Min. and Met.*, Vol. XVII (1907-1908), pp. 50-52.
The same reasoning demonstrates that the coarser the conglomerate the more permeable it would have been.

knowledge frequently influences the scheme adopted in planning the development work of a mine. Although this idea is prevalent throughout the Rand and is borne out by practical experience, yet few really careful observations have been made, or accurate data obtained, to substantiate this view. Fortunately, W. L. Honnold and C. E. Knecht,²³⁵ some years ago, compiled some interesting statistics and curves illustrating this relationship between these two gold-carriers of the two sub-series of bankets, which, as Walter McDermott has observed,²³⁶ is not an uncommon feature in parallel fissure-veins and in lenticular masses, the values jumping from one to the other, or changing between the two walls of veins. Considering in cross-section the Main Reef

Influence of Pressure

As previously mentioned, according to Riecke's principal, where pressure is greatest, there solution is most active. Thus where mineralizers, ascending under pressure encountered obstructions in the form of occasional reductions in the size of one of the channels, there dissolution of the walls and of the banket would, doubtless, commence, causing increased precipitation of the mineral and metallic contents of the solutions. Such considerations do not, however, fully explain the regularity of the alternations in value between one layer of banket and another. The assay-values seem to oscillate from seam to seam with a periodicity so regular that

FIG. 24.

series as a whole, at the time the mineralizing solutions were coursing through it, then for any section a certain quantity of solution would have passed in a given time, from which, presumably, a definite amount of gold would have been precipitated. Therefore, if through any cause more was precipitated on, say, the Main Reef Leader side of the section, less would be precipitated on the other, or South Reef Leader, side. It is easy to understand how slight mineralogical variations, or variations in the width of the conglomerates, might cause greater or less precipitation; the former for chemical, the latter for physico-chemical reasons. For example, greater precipitation due to great frictional resistance might occur where one of the channels was restricted.²³⁷

²³⁵It is to be hoped that Messrs. Honnold and Knecht (managing director and consulting engineer, respectively, for the Consolidated Mines Selection Co.) will publish the results of their investigations on this important matter.

²³⁶Discussion on J. W. Gregory's paper, 'The Origin of the Gold in the Rand Banket,' *loc. cit.* p. 56.

²³⁷In this connection it is interesting to compare the horizontal quartz veins, or ore-sheets, in the dolomite of the Pilgrim's Rest district of the Northern Transvaal. These reefs are worked by the Transvaal Gold Mining Estates, Ltd., and by others. They vary in thickness from 1

it should have some fairly simple explanation. Probably this is due to the influence of what are usually known as 'pitching troughs and arches': the conglomerates do not present a strictly plane surface; crumpling of the strata has produced, along the direction of the strike, a series of flexures, which would have presented to circulating solutions a series of crests and troughs, and these may have affected the deposition. These flexures are especially noticeable in the drives underground. When the banket is carried, say, shoulder high on the foot-

or 2 in. up to about 2 ft.; but are sometimes much thicker over considerable distances; and in this case it is these thicker portions, long and relatively narrow, termed ore-channels, that are usually richer than other parts of the 'reef' (see 'The Dolomite Formation of the Transvaal,' by C. B. Horwood, read before the British Association, 1905). In this case the horizontally-moving solutions would doubtless have been under less pressure and have been more sluggish than the up-rising mineralizers in the bankets. The enrichment is presumably due to greater precipitation owing to lessened rate of flow where enlarged portions of the channels were traversed. (See Posepny, *loc. cit.*, p. 14.) Similarly, the speed of a river is checked on entering a lake and precipitation of suspended matter is thereby increased; the difference merely being that in the former case the material was in solution, while in the latter it was in suspension.

wall side of the drive, the resulting drive will not be straight, and will be represented on the mine-plan by gently curving lines, as shown below:

Considering the two leaders and one of the folds when, for example, the South Reef Leader forms an arch, that is, when it is on the convex side of a

the gold contents of the two sub-series vary in relation to each other. The ore reserves of one mine for the two lodes above and below a given level were calculated separately. The vertical depth of the bottom of the mine below the surface was about 2300 ft. and of the 9th level about 1200 ft.; and the ore reserves were calculated for each lode, separately, above and below this level, with the following remarkable results:

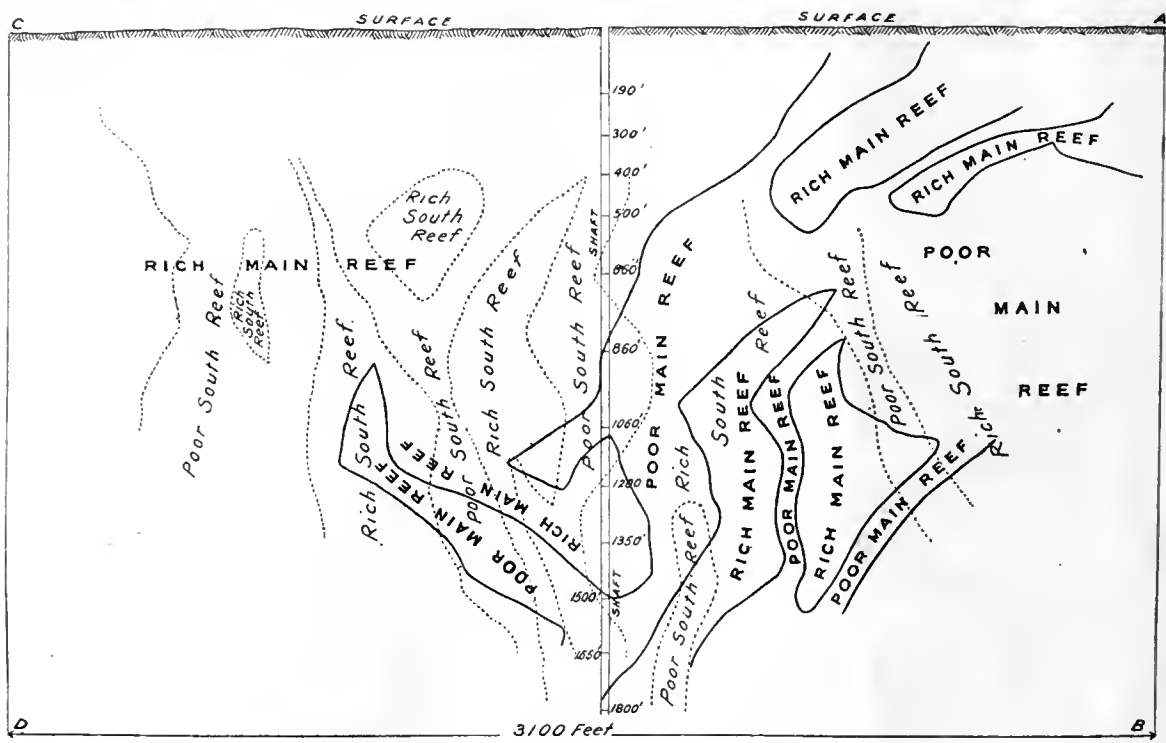

FIG. 25.

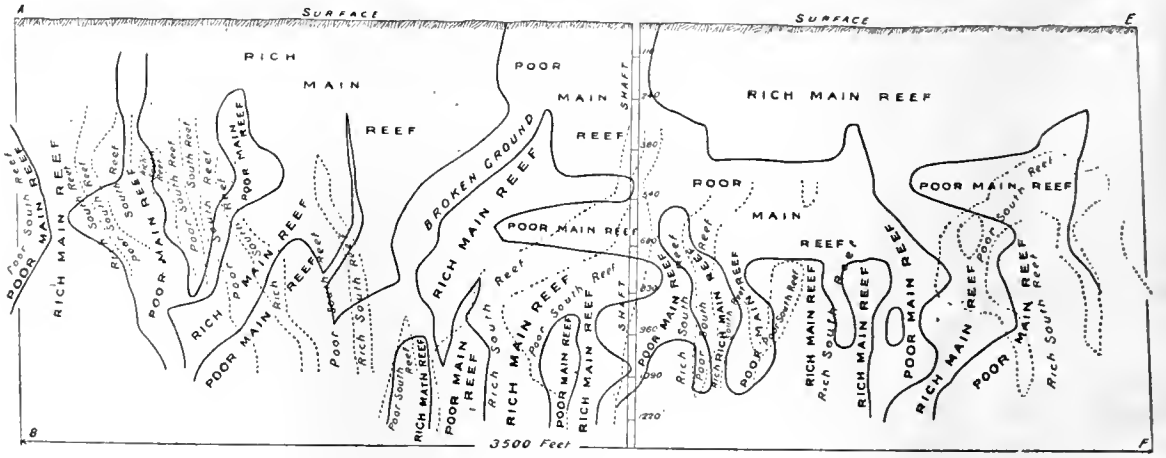

FIG. 26.

fold, its radius of curvature being somewhat greater it will have suffered somewhat greater tensile deformation than the corresponding portion of the Main Reef Leader, which being on the lower, or inner, side of the fold, will, relatively speaking, be under compression, will consequently have been slightly more porous. When it forms a trough, that is, when it is on the concave side of a fold the reverse will have been the case, it will relatively have been subjected to compression. These alternations of greater and less porosity may have influenced the deposition of the gold.²³⁸

The following is a good example illustrating how

South Reef Series:	Tons.	Value.
Above 9th level	229,800	9.7
Below 9th level	109,900	8.4
Total	339,700	9.3
Main Reef Series:		
Above 9th level	152,700	7.7
Below 9th level	146,500	9.3
Total	299,200	8.9
Both Reef Series:		
Above 9th level	382,500	8.9
Below 9th level	256,400	8.9
Total	638,900	8.9

²³⁸See "The Bendigo Goldfield," by T. A. Rickard, *Trans.* Amer. Inst. Min. Eng., Vol. XX (1892), pp. 463-545; and also Van Hise, *loc cit.*, pp. 405-412.

These figures show clearly that, for the mine as a whole, above the 9th level the upper series is the richer; but below that level, as it becomes poorer, so the lower series simultaneously become richer. That there is not exact compensation between them is clear from the curious coincidence, shown in the

mines, which are shown, in vertical section, in Fig. 25 and 26, respectively. They illustrate how the gold content of one sub-series of blanket goes up, as the other goes down, and the reverse. The gradual decline of grade in depth is distinctly indicated by the mean line shown in Fig. 24.

FIG. 27a.

third statement, that the combined value of the two both below and above the 9th level are the same; but, since the tonnages developed on each lode are different, it follows that there is not exact compen-

Fig. 27 shows three curves compiled about 7 years ago for one of the deep-level mines of the Central Rand.²⁴⁰ Unfortunately, only a small portion of the total area of the mine had as then been worked

FIG. 27b.

sation as regards assay-values. Fig. 23 and 24 are of curves²³⁹ compiled from data relating to two

²³⁹These curves were made to accompany the plans shown in Fig. 25 and 26, and were constructed in the following manner. The average for each level was obtained by averaging the assay-values shown for every 50 ft. along the whole length of each level. The data so obtained were plotted. In the case of the 7th level on the Main Reef series, shown in Fig. 23, one of its two drives had only been advanced a short distance from the cross-cut from the shaft, as it had encountered a poor patch of ground, known to be of considerable extent. The part already

and it had a long life ahead of it, so that the up-driven was in rich ground. The corresponding drives above and below extended a long way beyond where this 7th level drive ended. The average value for each of these two drives, beyond this point, was therefore added to the average value of the 7th level drive, and the average of these three values was taken as the average for this lode on the 7th level.
²⁴⁰It is a pity that these curves have not been brought up to date. They should be compiled and kept up to date for every mine on the Rand, as they would afford most valuable information.

ward tendency of the grade from the 4th to the 7th level, as shown in curves a and b, does not imply that the mine as a whole is becoming richer in depth; in fact, since then the grade has gradually dropped, as one would expect. Curve c in Fig. 27 shows the gradual drop in the width of both lodes from the 2nd to the 7th level from an average of about 30 in. down to an average of about 18 in., and suggests the greater compactness of the strata in depth as the cause.²⁴¹ The first curve shows the inch-pennyweights; that is, the assay of each

When comparing the Rand with other goldfields, the fact is apt to be overlooked that gold-quartz mines usually have only one vein on which to rely, while the mines of the Rand are double, or twin, mines, with two lodes superimposed. If the alternations between good and poor zones were less frequent, and if there were not a second lode on which to fall back, then extensive good zones or shoots would alternate with extensive unprofitable zones and the conditions would approach more closely to those of ordinary fissure-veins.²⁴³ With agencies so

FIG. 27c.

'reef' in pennyweights of fine gold per ton multiplied by its thickness in inches. The second shows the stope-values for each lode. Both clearly indicate how as the curve for the one 'reef' ascends, that for the other descends, and conversely.

Zone of Secondary Enrichment

A noticeable feature of the first two curves is that they indicate the presence of a zone of secondary enrichment below the oxidized zone, which ends at a vertical depth of about 300 ft. Fig. 23 and 24 showed that the richest portions of this zone are at the 7th and 6th levels, respectively, of the two mines for which these curves were compiled. Curve a in Fig. 27 shows that the richest portion is below the 7th level, and curve b of the same figure suggests that it is probably in the neighborhood of the 8th level of the deep-level mine to which they relate.

Fig. 25 and 26 were made from the large assay-plans²⁴² of the two mines before-mentioned. In each case, tracing-cloth was put over the full-size mine assay-plan of the one lode and the profitable and unprofitable zones were indicated as accurately as possible. The same cloth was then placed over the assay-plan of the other lode of the same mine, and its profitable and poor areas were marked on it; these were then photographed down to the present size. They illustrate clearly how each lode alternates regularly, along the strike, between poor and rich zones or shoots.

potent that they mineralized two parallel neighboring lodes to such a degree that they are profitable for a distance of about 55 miles,²⁴⁴ extensive areas of unprofitable ground can, fortunately, hardly be expected.

(To be Continued)

State aid to mining in New Zealand has included the use by prospectors of the government diamond-drills and two Keystone placer drills, which are loaned free of charge save the cost of wages, repairs and material used. During 1912, 156 holes were drilled a total of 6670 ft. in gravel, and 3 holes a total of 1158 ft. in search of coal.

Gold produced by hydraulicking in New Zealand in 1912 was worth \$1,280,000.

²⁴³However, extensive areas of poor, and even of unprofitable, banket do occasionally occur. This is especially so with the South Reef Leader, and would result in unprofitable mines were it not for the fact that there is still the Main Reef Leader, which is generally sufficient in itself to result in productive mines. On the Far East Rand the lower of the two lode series, which is correlated with the Main Reef series of the Central Rand is locally known as the Van Ryn series. The gold of this district is largely confined to the lowest member of this series, which rests on a shaly talcose foot-wall. The available evidence indicates that in this portion of the Rand the alternations between rich and poor ground are less frequent; that is to say, the poor patches are of greater extent, but they occur less frequently, and so the differences in grade should, over larger mine areas, compensate each other, as they do over smaller stretches of mine ground along the Central Rand.

²⁴⁴Corresponding to a total length of single lode of nearly 110 miles. See, however, that portion of the previous footnote which refers to the far East Rand.

²⁴¹This confirms C. R. Van Hise's investigations that fissures gradually die out in depth. (See Van Hise, *loc. cit.*).

²⁴²The scale of the original working plans from which they were made was 1:500.

Steel Ore Passes at Broken Hill

By JOHN M. BRIDGE

*Up to the present time timber has been used in underground operations to the almost total exclusion of all other materials; a fact which is accounted for by its universal distribution, by the ease with which it is worked by simple appliances and comparatively unskilled labor, and by its strength and resistance to wear, to decay, and to the action of mineral waters. But the exhaustion of the supply of cheap timber, combined with the increasing production and decreasing cost of steel, and the appliances for working it, is bringing the latter more and more into competition, especially when the duty is heavy and the wear and tear great. So, wooden rails and cars have long since disappeared from metal mining, and now steel and reinforced concrete are coming forward as mine supports. It is not surprising, therefore, that this tendency should extend from the rails and trucks to the chute door, chute lip, and finally to the chute itself.

Requisites of an Ore Pass

The essential requisites of an ore pass are, that it must have a life at least equal to that of the stope it serves, a minimum tendency to 'hang-up,' a fitness for stopping conditions, and the universal desiderata of small first cost and maintenance. Before considering the steel pass in particular, it is as well to note some of the other means adopted as a link between stope and level. The following are some of the methods by which the problem is being solved: (a) Square cribbed passes of round or square timber, with plain or joggled ends, either built by themselves, or immediately inside the legs of square sets, and projecting over the caps and struts for additional support and rigidity; (b) square-set passes lagged outside, and lined inside with vertical timbers spiked on to each set, or with the cribbing just mentioned; (c) circular stone passes hand-packed, sometimes bonded and strengthened by occasional timbers placed radially; (d) circular wooden passes of radially-shaped timbers placed vertically, the grain of the timber being parallel to the axis of the chute in line with the fall of the ore; (e) circular steel passes. These passes have been used on the South Blocks mine, Broken Hill, for the past five years, and continue to give satisfaction under the conditions existing there. The first to be installed were 16 in. diam. by $\frac{3}{16}$ in. thick, being rolled from 4 by 4-ft. plates. The vertical joint was made by riveting a cover plate on the outside, and the lugs for fastening one length to the one below were also riveted.

As these proved too small, 20 in. diam. rolled from 4 by 5-ft. plate were tried, and met with a similar fate. Next 30 in. diam. by $\frac{1}{4}$ in. were tried, made from 4 by 8-ft. plates, and similar in construction to the others. The size of the latter proved adequate, but the riveting was a source of weakness, as the heads of the rivets got worn off, partly by abrasion, but mainly by the constant jarring of the falling ore.

This loss of rivets, in the case of the longitudinal joints, allowed the tube to bulge, and caused the chute to hang up, and the defect was aggravated by firing the chute at this point to bring the ore down. In the case of the lugs becoming detached, the tube to which they belonged slipped down, and left an annular space, in which the ore again collected and hung the pass up. To overcome this defect the present type of tube was adopted, having no rivets at all in the lugs, and those in the longitudinal seams being placed far enough back from the side of the chute to deaden the jarring effect.

The sections as now used are made by cutting the 4 by 8-ft. plates by means of an $\frac{1}{2}$ -in. slotting punch, the final cut in every case being made with a round instead of rectangular punch, so as to give a round root to the lugs to prevent tearing. The circular holes for riveting, and for attaching the slings, are punched at the same time, and by the same machine. Provision is made for three lugs on each longitudinal and also on each circumferential seam, the bottom longitudinal lug also serving as an additional circumferential support. After cutting, the plates are bent uniformly in the rolls, until the opposite edges about touch. The various lugs are next put on, in all cases being bent cold by hand, by means of a dog made of a 3-in. head, having a slot in it 4 in. deep by $\frac{1}{2}$ in. wide, and provided with a stout iron handle. The lugs of the longitudinal seams are bent out square in one operation, but those for the annular joints are first bent out square to the axis of the tube; then the hold of the dog is shortened, and they are bent back parallel to the axis. The edges of the longitudinal seams are then pulled up together and riveted.

The Starter

The first section of each pass, or the 'starter', as it is called, has the same longitudinal joint, but the lugs are replaced by 4 by 4 by $\frac{1}{2}$ -in. angle-iron feet which rest on the chute timbers, and form the foundation for the pass. Riveting is again avoided by attaching the feet to the tube in the following manner: Three pairs of circumferential slots, $2\frac{1}{2}$ in. long by $\frac{1}{2}$ in. wide, are punched, 2-in. centres; the $1\frac{1}{2}$ in. metal left between is then sheared in the centre, and the two pieces of metal forced back to make two $1\frac{1}{2}$ by $1\frac{1}{4}$ -in. lugs. Over these is placed a 5-in. length of 4 by 4 by $\frac{1}{2}$ -in. angle iron, slotted to fit the lugs, and these lugs are then hammered back to grip the angle iron. Half, and three-quarter tubes are also used, being made from 2 by 8-ft. and 3 by 8-ft. plates, the object being to suit the height of the filling in the stope. The end dimensions of these short tubes are the same as the ordinary ones, but the central longitudinal joint has to be dispensed with, from lack of room on the plate. The different lengths of the slots and lugs on the top and bottom circumferential seams, gives the required taper to each tube. The top of each section has a minimum inside diameter of 2 ft. 5 in., and the bottom a maximum outside diameter of 2 ft. $4\frac{3}{4}$ in., to allow of fitting each tube

*Abstract from *Proc. Aus. Inst. Min. Engineers.*

into the one immediately below it. Three thicknesses of plate are used, $\frac{3}{8}$ in. for the first 60 ft. above the level, $\frac{5}{16}$ in. from 60 ft. to 110 ft. and the remainder $\frac{1}{4}$ in.; the cost complete of each section, from 4 by 8-ft. plate, being respectively \$19.20, \$18, and \$15.60.

Construction

In starting from the level, two foundation pieces of 10 by 10-in. Oregon pine of a length to suit the conditions, are first put in, resting on a 2-in. projection of the caps of the level sets; an additional hold sometimes being given by spiking a 4 by 10-in. piece on to the legs vertically. Two pieces 7 ft. by 10 in. by 10 in. are next placed transversely to these, blocked 2 ft. 5 in. apart, and then two 5-ft. pieces parallel to the foundation pieces, and likewise blocked 2 ft. 5 in. apart. The starting tube is fitted between these, the lugs resting on the top of them, and the whole is made rigid by packing with filling. The passes are placed 30 ft. apart along the level, and in some cases have been taken up 140 ft. above the back of the drift, in stopes averaging 30 ft. wide, representing a tonnage handled per pass of about 15,000 tons, without any renewals or repairs. Some of the passes have been lost, but most of these were 16 and 20-in. tubes, the balance being ruined by firing with gelignite when clogged. Repairs are difficult, but provided care is taken to avoid sharp bends, which allow the ore to pound out the under side of the bend, and no firing of clogged passes is permitted, no repairs are necessary where the passes are properly spaced for economically handling the ore in the stopes. When hung up, the ore can in every case be brought down by shooting with a 'cannon,' made by boring a 2-in. hole in a piece of 5-in. shafting, and using gunpowder to fire a projective at the mass. Clogging is to a great extent avoided on the South Blocks mine, as skip haulage is used, and it is not necessary to use the passes for ore storage, as the shaft-bins serve that purpose more effectively. The advantages of these passes are: (a) Their moderate first cost and great wearing qualities, which eliminate renewals and repairs; (b) the small size they can be made, without an undue tendency to clog, lessening the chance of accident by falling into them; (c) their adaptability to stoping conditions, as no special care is needed when firing ground on top of them; (d) their impervious nature, which prevents any very rich ore being lost, and also confines sand filling to the stope, which is a matter of great difficulty in very wet mines; and (e) the ease and cheapness of installing each section, as each tube is made so that it fits the previous one.

The result of the use of these passes on the South Blocks mine has proved, that for the conditions existing there, the steel pass can do its work quite as well as any form of timber pass, and the question of its adoption is one which depends directly on the relative prices of steel and timber.

Queensland's gold production in September amounted to 22,220 oz. fine, according to the *Government Mining Journal*. The value was £94,385, and the month showed a decrease of 7037 oz. and £29,891 as compared with September 1912.

German Workingmen's Insurance

*The avowed object of workingmen's insurance is to safeguard the working population in its economic existence against the unavoidable dangers and injuries connected with its calling. Within the German empire every working man and working woman is, without any distinction of nationality, insured in accordance with the law of the land against sickness, accident, invalidity, and old age. At the present time persons industrially employed in their own homes, agricultural laborers, and domestic servants are not yet subject to compulsory sick insurance. Accident insurance applies in the main to persons employed in factories. The larger number of persons employed in domestic industrial work are likewise still exempt from invalid insurance.

Sick Insurance

Insurance under this head is effected by means of sick insurance funds formed severally for each particular branch of employment and restricted to small districts. Such funds are administered jointly by employers and employed under the supervision of the state. Of the entire cost of such insurance employers pay one-third and employed two-thirds. The benefits assured by the insurance to an employee falling sick are: gratuitous medical treatment and medicine (including the provision of spectacles, trusses for ruptures, etc.), also sick-pay beginning on the third day of sickness. In case of death, burial money is allowed to the family. In cases of confinement benefit is allowed for the space of six weeks. Since its creation in 1885 sick insurance has insured to working folk (in 1909 there were 9,946,585 men and 3,457,713 women) the following benefits:

	Million marks.
For medical treatment.....	845.1
For medicine, etc.	615.9
Sick-pay to invalids.....	1736.2
Sick-pay to those dependent on them.....	39.5
Confinement pay	63.7
Maintenance of hospitals.....	510.6
Burial money	122.0
Other expenses	61.4
Total	3994.4

The disbursements in 1909 alone under this head amounted to 342,200,000 marks. And the accumulated surplus under sick insurance figured at the close of 1909, at 286,525,100 marks.

Accident Insurance

Accident insurance (applying in 1909 to 14,854,000 insured men and 8,913,000 insured women) is effected by means of insurance funds formed severally for distinct groups of employment. These funds are administered by the employers alone, who are called upon to pay the entire expenses occurring, under supervision of the state.

The benefits accruing under this head to an employed person disabled by an employment accident (sick insurance being afforded him or her during the first thirteen weeks) are: medical treatment, medical

*Abstract from a government report and printed in the *Bull. Amer. Assn. Com. and Trade, Berlin*.

requisites such as, crutches, invalid appliances and the like, and, during the period of disablement, a pension, all beginning in the fourteenth week after disablement. In cases of total incapacity an allowance equal to two-thirds of the money previously earned in employment is paid as a full pension; in cases of only part disability a pension is paid in proportion. Should the accident have proved fatal, burial money is allowed and the surviving dependents also receive pensions. The insurance fund issues regulations for the adoption of measures and appliances designed to prevent accidents in the places of employment concerned, for the better protection of the persons employed in them, more particularly, protective devices for machinery. The insurance funds also employ all conceivable care to bring about a perfect recovery of the injured workpeople and to preserve their capacity for earning wages. With this end in view they have, among other things, established special hospitals.

Injured working folk may refer claims to specially instituted tribunals for adjudication in matters of workmen's insurance, and beyond these to the workmen's insurance department for the empire or else for the particular state.

Since its first creation in 1885 the accident insurance department has expended the following sums of money in carrying out the duties entrusted to it:

	Million marks.
On treatment for recovery.....	44.7
On care during the first 13 weeks.....	10.6
On hospitals and orthopaedic institutions.....	67.2
On pensions to dependents during treatment.....	18.3
On pensions to injured people.....	1304.2
On capital commutation to natives.....	12.4
On burial money	10.4
On pensions to dependents.....	324.4
On compensation, specifically to widows.....	12.2
On compensation to foreigners.....	3.9
Total	1808.3

In 1909 alone 162,266,000 marks were expended in this class of insurance. The accumulated surplus of the funds amounted at the close of 1909 to 510,737,000 marks.

Old Age Pensions and Invalid Insurance

Insurance of this kind (embracing in 1909 10,707,100 men and 4,737,200 women insured) is effected by means of insurance institutions established for large districts (provinces or independent states) and administered by public officers of superior position assisted by representatives of both employers and employees, under the supervision of the empire. The expenses are borne in equal shares, one half each, by employers and employees, the empire adding to each insurance a fixed grant of 50 marks per year.

Working folk insured receive pensions, upon disablement (invalidity) being shown, or else upon attainment of their seventieth year. They are likewise allowed pensions in cases of sickness after the close of the first 26 weeks. Up to that time sick insurance funds provide for them. In cases of sickness the insurance institutions also apply very carefully conducted curative treatment, in order to prevent, if possible, sickness degenerating into permanent invalidity. With this end in view the insurance

institutions maintain a considerable number of hospitals, sanatoria, hospitals for consumptives and the like, entirely for their own use. Also they send incapacitated working folk to watering places, or else provide them with artificial limbs, trusses, stays, boots for defective feet, and the like. The same institutions furthermore devote a considerable portion of their accumulated surpluses to the promotion of establishments ministering to the well being and health of the German working population generally, more particularly for housing purposes. Working folk coming under this insurance are entitled to adjudication of their claims by tribunals similar to those constituted under accident insurance.

Since its establishment in 1891 old age and invalid insurance has secured to the working folk whom it affects the following benefits:

	Million marks.
Curative treatment	131.5
Extraordinary benefits	6.1
Treatment in hospitals.....	2.9
Invalid pensions	1186.0
Sick pensions	25.9
Old age pensions	423.5
Return of contributions made.....	95.7
Total	1871.6

In 1909 alone expenditures amounted to 189,029,000 marks. At the close of 1909 the accumulated surplus stood at 1,574,111,000 marks. Out of this surplus the following investments had been made:

	Marks.
Investment for purposes of common utility....	829,324,554
Hospitals, sanatoria, and recreative homes	445,934,433
Workingmen's dwellings	280,517,984
Agricultural credit	102,872,139

German Workingmen's Insurance as a Whole.

From the time of its first introduction to the close of 1909 workmen's insurance has disbursed for the benefit of working folk:

	Marks.
Sick insurance	3,994,400,000
Accident insurance	1,808,300,000
Invalid and old age insurance.....	1,871,600,000
Total	7,674,300,000

In 1909 the disbursements were as follows:

	Marks.
Sick insurance	342,200,000
Accident insurance	162,266,000
Invalid and old age insurance.....	182,029,000
Total	693,495,000

Accordingly German workingmen's insurance paid to working folk 1,900,000 marks per day. Accumulated surpluses amounted at the close of 1909 to 2,371,373,000 marks.

During the twenty-five years of its existence German workingmen's insurance has shown itself to be, in fulfilment of the words of the imperial message of November 17, 1881, and written by Emperor William I, an effective "institution for the furtherance of the well-being of the working classes." Beyond that, it has become a pillar and cornerstone of the measures taken in the German empire for the promotion of public health. Under it employer and employees have been brought together for common administration.

Zinc Smelting in Australia

The Port Pirie plant of the Broken Hill Proprietary Co. is described at length by F. W. Reid in the *Mining and Engineering Review*, of October 6. This plant was built as the natural result of successful application of flotation to Broken Hill ores. The concentrate as received at the smelter contains about 46% zinc, 8% lead, 13 oz. silver, and 30% sulphur. It is roasted in Hegeler furnaces fired with gas from Duff producers. The capacity of the double, 7-hearth furnace is 48 tons per 24 hours.

For the distilling plant retorts and condensers are made on the ground, as is customary in the United States. The retorts are hydraulic pressed, dried, and fired as usual.

The Spelter Plant

The plant comprises 10 furnaces, 8 of which are at present in commission. The furnaces are of the Rhenish type, having two tiers of retorts, back to back, with three rows of 24 retorts in each tier, or 144 retorts on the whole furnace. The outer wall on each side is built with 3 rows of 12 openings, each accommodating 2 retorts. The outer ends of the retorts rest on the tiles forming the sills of these openings, while the inner ends are supported upon corresponding sills of an interior frame-like wall. They are set with a slight inclination toward the front, and, being supported at the ends only, the flames can play freely round them. The retorts are 5 ft. 6 in. long, and 13 by 7 in. elliptical cross-section. The condensers, which are open at both ends, are made of the same material, and in the same moulds as the retorts, being simply the latter cut in two. When the retorts are in position in the furnace their ends, which have been beveled on the outside, are well smeared with clay, and the condensers, with their ends beveled in the opposite direction, forced up against them. The condensers rest upon the tiles which support the front ends of the retorts.

The furnaces are gas-fired, there being a producer for each furnace. The air for combustion of the producer gas is preheated on the counter parallel current system, being forced, by means of a fan, through an intricate system of flues and round the furnace itself, before reaching the burners. The latter, of which there are four, are built in the form of large Bunsen burners in the hearth of the furnace, between the two tiers of retorts. They are 18 in. diameter, with gas inlet 9 in. diameter, at the bottom, and air ports at the side. Both air and gas can be regulated.

In running the furnace, one man works 24 retorts. The charge consists of roasted zinc concentrate, with fine coal and coke as reducer, the latter amounting to 40 to 45%. A typical charge is 10,000 lb. ore, 3000 lb. coke, and 1500 lb. coal. Condenser chip-pings and oversize blue powder are also added to the charge. After being mixed on the furnace floor, the charge is shoveled into the retorts through the condensers. The retorts of the top and middle rows receive the regular charge, while the bottom row, which is not so strongly heated, is charged mainly with dross—a mixture of coke, blue powder, and

metallie zinc, seraped from the condensers during tapping operations.

After charging the retorts the ends of the condensers are stopped by luting on cast iron tiles lined with fireclay on the inside and provided with a hole for outward passage of vapors. Over a projecting collar surrounding the hole is fitted the small end of a conical sheet iron 'prolong,' the other end of which is supported by a moveable bar resting on brackets on the front of the furnace. The prolongs serve to collect blue powder. The carbon monoxide escapes at a small hole at the outer end of the prolong. When the prolongs have been fixed in position the furnace is fired and distillation allowed to proceed. The temperature is taken at hourly intervals by means of a Wanner pyrometer. It is raised gradually until it reaches a maximum of 1325 to 1350°C. An hour or two before the day shift comes on the prolongs are removed and the contained blue powder collected. The furnace is then ready for tapping. The tile on the end of the condenser is removed, the molten zinc allowed to run into a cast iron ladle placed to receive it, and the condenser thoroughly seraped to remove all zinc and dross.

Raking out the retort residues is the next operation. For this purpose counterbalanced sheet iron aprons are pulled down in front of the furnace and rakes inserted through openings opposite the retorts. The residues, deflected by the apron, fall through an opening in the floor close to the front of the furnace, and run by a chute into trucks below. They are sent to the lead blast-furnace for recovery of the lead and silver contents.

The furnace is next tested for cracked retorts. This is done by simply turning on the gas, when cracks can be detected by the flame coming through into the interior of the retort. Damaged retorts are replaced by new ones, and after fitting the latter with condensers, recharging is commenced. The cycle of operations on the furnaces occupies 24 hours.

The capacity of each furnace is 5 tons of roasted material per 24 hours. The zinc recovery in spelter and marketable blue powder is said to range from 80 to 85 per cent.

The blue powder averages about 12% of the total furnace product, and is of very good quality, containing 92½% metallie zinc. It is screened through a 100-mesh screen, and boxed for export to San Francisco or Japan, its two markets. Blue powder is used in the galvanizing process known as 'sherardizing,' and also finds an application in the Merrill process for precipitation of gold and silver.

Refining the Spelter

The spelter contains 2 to 3% lead, and is sent to the refinery, where it is liquidated in a reverberatory furnace. The charge is about 20 tons. The lead sinks to the bottom, and is allowed to accumulate for a week or more before it is tapped. It contains 0.7 to 0.8% zinc. The spelter is ladled out at one end of the furnace, having first to pass under a baffle plate, which, dipping into the bath, holds back the dross. The latter, which is small in quantity, is skimmed off and returned to the zinc plant. The spelter, now ready for export, contains less than 1% lead, and approximates 99% metallie zinc.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Nitrogen Supplies

The Editor:

Sir—In an editorial in the *Mining and Scientific Press* of September 20, 'Trailing the Nitrogen Atom,' it is stated that at the present rate of production (3,000,000 tons per year) the nitrate deposits of Chile will not last over half a century more. I wish to rectify this assertion by quoting from a speech of Secretary of the Treasury, Sr. Arturo Alessandri, delivered at the session of the Congress of Chile of July 5 last. Sr. Arturo Alessandri said:

"The Government Nitrate Land Office has surveyed and prospected, up to this date, 1,452,750 acres of nitrate lands and the nitrate ore there available, if mined and reduced according to the methods now in use, will yield 270,410,000 tons of commercial nitrate. In making this calculation, nitrate beds of over one foot in thickness and assaying over 15% NaNO_3 , have only been accounted for, leaving out of consideration all the nitrate beds below the specified minimums. The nitrate lands extend over a territory 430 miles in length, covering a surface of over 50,000,000 acres; of this territory, as stated above, only 1,452,750 acres have been prospected, that is to say, only 1/34 of the whole surface."

JUAN BLANQUIER.

Berkeley, California, September 29.

Under-Estimating the Cost of Milling Plants

The Editor:

Sir—In reference to Mr. Additon's paper and Mr. Hutchinson's comments, I hope you will allow me a few lines. Most writers refer all their estimates and data to milling plants of large size. The truth is that most gold-milling plants erected are five or ten-stamp mills. It is easy enough on a big job to have a head for each department and systematize the working so that the mine superintendent has nothing to do but wait for the complete job, but the fact is that the majority of mills built are small affairs, and also most of the mills have not been justified by the condition of the mine, and a large per cent of mills have been financed by companies with insufficient capital to build a proper mill.

The reason why many companies prefer their superintendent to erect the mill is that the money is not on hand to pay a machinery house or a contractor, for while the promoter or 'head push' may be able to raise sufficient money for monthly wages, he cannot raise the amount necessary for the payments demanded by the machinery house. It may be asked, why not wait until all the money is in? The answer to this is that the money will not come in unless the mill is under way. Why? Ask the buyers of mining stock. It is their way of investing.

There are machinery houses manufacturing stamp-

mills that make poor plans, and there are mine superintendents who know nothing about constructing a mill. In respect to the former, to use the words of the immortal poet, "I could a tale unfold whose lightest word would harrow up thy soul, and each particular hair to stand on end." As to the latter, so long as mine superintendents and mining engineers exercise their profession without regulation by the state, it must be expected that men with no qualifications will be running mines and building mills.

If all the factors entering into costs of construction were known, it might be an easy matter, by following Mr. Additon in detail, to estimate very closely the cost of constructing a given plant; but these data, or at least some of them, are never known beforehand. Take a few examples. I send for an estimate on the cost of corrugated iron f.o.b. Chicago. When I come to order my iron, say in two months' time, the price has increased, and so my estimate is off that difference. Again, my plans call for 71 inches between battery-post shoes. When the mortars arrive, I find the factory allowed 72 in. I must then take out an inch. In the case of cast iron battery-post shoes, I chip half an inch from each shoe at a cost of \$50 per battery. You will say, why not recover this from the machinery house? The answer is that the machinery house has been paid, and without a lawsuit the money cannot be recovered, and it is not worth the cost of a suit. You might say, 'But why was all the money paid to the machinery house before the mill was delivered on the ground?' The answer to this is only that it was paid by the directors without your advice. But look at the delay and cost which was not reckoned in the cost sheet. Then again, the motors sent, while supposed to run at a certain speed under full load, for one reason or another exceed or go under the necessary speed, requiring a change of pulleys on the transmission shafts. The machinery house again? No, the power company this time, for the frequency of the alternations at the power-house is over what you expected, and the power company has no agreement to supply you with any certain frequency or constant voltage. The truth of the matter is that some machinery houses are very careless, both in respect to plans and sending machinery in first-class shape, and I am prepared to back this up by proofs; but these facts are known to all constructing engineers. Four machinery houses with whom I have dealt in putting up a mill added an extra cost to a 10-stamp mill of \$1500 indirectly and \$500 directly on repairs and alterations. Quite an item to be charged against you. This does not count the weeks of delay with running expenses being charged to construction account.

There is one item of cost, or at least it should be considered as an additional cost, that has not been touched upon at all. This is when money for building a mill comes to the superintendent in small amounts. For example, he has instructions to build a mill, and the ore in the mine justifies such a course. Money is sent for the first payment on machinery, and then it is a constant struggle to pay men and buy machinery. You dare not send away for expert

workmen for fear of not having the money to pay railroad expenses, and local talent must be relied upon. A mill that could have been put up for \$20,000 in three months, drags along to from six to eight months, and the cost has gone away over the estimate. The superintendent is blamed, but not rightly; for when his estimates were made, it was on the basis of all the money being on hand to complete the mill and the work was not to be extended over a long period, with the big running expenses being charged to construction. The increased cost will amount to from 20 to 40% where the money is not on hand.

Now, as to who should build a mill—the superintendent or a machinery house—I should say that the plans should be made by the machinery house and submitted to the criticism of a metallurgical engineer (whose business was mill construction) in conjunction with the mine superintendent, and then the erection should be done by a contractor under the supervision of the superintendent. My reasons for such a procedure are as follows. The machinery house has a staff of trained draughtsmen who are accustomed to such work, and they have probably designed many mills. At the same time, the machinery houses often lag behind in the use of new structural material and the relation of their machinery to other machinery in the mill made necessary by the process to be used. Here is where the knowledge of the metallurgical engineer is necessary, one whose business has taken him to many camps where new ideas are being tried, whose scientific training gives him a rapid insight into construction details, and who is not tied to any set form of construction. But neither the machinery house nor the metallurgical engineer knows the details of the character of the ore, the amount of ore on hand, nor the financial condition of the company, so well as the superintendent, and as the latter must eventually use the mill and be responsible for all its defects, his voice must be final.

Few mine superintendents are fitted by nature or experience to erect a mill, nor is it a good plan for them to do so, for other work must be neglected. There are cases where he must do it, and even cases where the cheapest machinery and structures are justified. I may cite a case. This company had on the dump 25 tons of ore and not another ton in sight in the mine. To be able to raise money to continue development, it was necessary to erect a mill. The superintendent advised against this, and told the directors that in two days after the mill started it would be useless; but it was a case of go ahead or lose his job, so he put up a mill. Now in this case a machinery house could not do any sort of a job and be able to put up a mill for 25 tons of ore as cheap as the superintendent could. No; the superintendent put up the mill to run through 25 tons of ore, and there the mill is to this day. Any other expense than absolutely necessary was not justified, and if the mill as it now stands is not a model, do not blame the mine superintendent, but blame the directors of the company.

ALGERNON DEL MAR.

South Pasadena, California, September 10.

Revision of the United States Mining Laws

The Editor:

Sir—The report of the committee of the Mining and Metallurgical Society of America upon the revision of the United States mining laws sets forth conclusions which are in accord with prevalent opinion in the mining states of the West, and the recommendations are excellent as far as they go.

It is a recognition of the advance which has been made in geologic knowledge to propose the abandonment of the old provision of the law requiring that an actual discovery of valuable mineral should be made antecedent to the valid location of a mining claim. Although favorable 'indications' may not be followed by discovery of workable mineral, our present state of knowledge admits of drawing conclusions from superficial conditions that are more significant than were possible in times past. It is manifestly correct to encourage the application of geologic knowledge by giving to prospectors the right of establishing valid claims under such circumstances. On the other hand, the right to locate claims prior to the discovery of valuable mineral opens an avenue to serious abuses unless the public welfare be protected by suitable safeguards.

The object of giving to a discoverer of metalliferous deposits a prior right to possession is to encourage the development of the natural resources of the country. The sum paid for the land when patent finally issues is of less material importance than the addition which is expected to be made to the national wealth by the exploitation of the newly discovered deposit. A considerable proportion of the value of the deposit is distributed to the general public in the form of direct wages paid and of supplies purchased. These far exceed the nominal fixed value for which the Government confers the right of private ownership, and is of larger economic benefit to the commonwealth. The aim of the law clearly has been, and should always be, to stimulate not only development but actual exploitation. Unfortunately, the working of the law in practice has resulted in a great deal too much desultory and useless so-called 'development', whereby large areas of the public domain are held by individuals in a vague hope that some one sometime may be induced to buy the claims, or that adjacent mining companies may be compelled to buy them in order to get rid of objectionable neighbors.

No one with actual knowledge of conditions in the mining districts can doubt that the great bulk of the annual assessment work performed on mining claims in the United States is either dishonestly done, or is done perfunctorily without regard to effective development of the mineral deposits. A too common motive is to do as little work as will suffice to comply with the strict letter of the law and thus bar others from validly locating the same ground. This surely is not in the public interest; neither is it the intent of the statute. It would seem that this evil might be cured readily by requiring a locator of a claim to proceed to patent within a period after location sufficiently long to give a reasonable opportunity for development and yet sufficiently short to make it too costly

to acquire patent without having discovered a deposit that promises to be worthy of exploitation. The prospector would thus be put upon the same footing as the homesteader, who has a limited period within which to 'prove up' on his land.

The committee also does well to insist upon such record of locations of mining claims as shall admit of others ascertaining whether or not any certain piece of ground has been previously located. Every operator has experienced the evils of our present system with regard to this matter. The lack of uniformity in methods of recording from state to state and from one mining district to another complicates the difficulty. The 'mining district', as provided for under the existing law, has no reason for continuance now that the West has become well settled, with transportation facilities bringing every part within a short distance of the railroads. It would seem that in these days of swift communication there remains no need whatever for recording locations of claims on the public domain within the county or state in which the location may lie until the property shall have been patented and thereby made subject to local state and county taxation. Neither is there any reason for recording primarily in the local United States Land Offices. Many prospectors would not know, nor could they reasonably be expected to know, the exact jurisdiction of local Land Offices, but all citizens know that the Department of the Interior has jurisdiction over all the Government lands, and therefore Washington would seem to be the logical place for making record of locations.

Every postoffice might be constituted a receiving station for location notices, empowered to accept such documents and the corresponding fees, receipting to the depositor for the money paid and transmitting the papers and proper fees to the Interior Department. This would bring the facilities for prompt and easy recording to the very doors of the people most nearly and keenly interested, and would prevent many of the abuses and difficulties resulting from delay in receipt of notices sent for record and from actual fraud in recording which are not infrequent under existing conditions. There would no longer be opportunity for sidetracking a notice for the benefit of some favorite as occasionally occurs today in the offices of mining district recorders. Whether such use of the postoffice be feasible or not, record of location with the Interior Department at Washington would solve the problem in the simplest manner, and information covering any desired area could be obtained in the usual way through persons or corporations making a business of abstracting. At the present time it is often practically impossible to obtain data as to locations since many mining districts and counties make no pretense of indexing in accord with geographical position. One must know the name of the supposed locators or the names of the claims in order to find the record. If he knew that much, there would be comparatively little object in looking up the record except to ascertain the precise limits of the locations conflict with which it was desired to avoid.

Furthermore, the intent of the mining law is that

monuments should be conspicuous as a warning to others that the ground is located. In practice it is altogether too common to place the monuments in the least conspicuous places in order not to attract attention. We might well pattern after the Mexican law in this particular, which requires that each claim be so monumented that it be possible to see two other monuments from any one. This constitutes a great improvement over our system of monumenting only the corners, the end-centres, and the discovery point. There can never be doubt whether one is upon land that is open or located when the claims are defined by a string of monuments easily traceable around the boundaries.

Finally, it may be asked by what process of reasoning the locator of a placer claim, under any circumstances should be subject to loss of right to ground which may legally be taken up by a subsequent locator of an interfering lode claim? To accord the placer miner a prior right to locate a lode traversing his property seems inadequate protection. It might prove to him an unnecessary expense and a useless complication. The discoverer of a lode should locate subject to the rights of any prior placer locator to work his placer mine without interference from the operation of a subsequent lode locator. It is reasonable, and not without precedent in the case of ordinary land titles in many states and foreign countries, that a placer patent should be subject to a right of subsequent location of metalliferous lodes which may cross the detrital deposit, since the placer mine is necessarily temporary, while the lode mine may support a relatively permanent industry; but there would seem to be no reason why the conflicting interests should not be harmonized under the law instead of giving to one the right of practically destroying the other.

COURTENAY DE KALB.

Tucson, Arizona, November 5.

The Rand Banket

Sir—The title of the series of articles written by me, and which you are publishing, is 'The Rand Banket.'

I am surprised to see, in your issue of October 11 that you have changed this to 'The Rand Banket and Its Gold Content.'

I must request you to alter this title to 'The Rand Banket' and to insert this letter in a prominent position in the next issue of your magazine.

C. B. HORWOOD.

London, October 22.

[On October 21 we received a cablegram from T. A. Rickard asking us to correct the title to 'The Rand Banket' simply. This was done.—EDITOR.]

Next to gold the principal metal product of California is copper, the production of which decreased from 36,316,136 lb. in 1911 to 33,451,672 lb. in 1912, but the value increased from \$4,539,517 to \$5,519,526. The relatively small production of silver is recovered largely as a by-product in the copper mines.

The total value of the mineral products of Arkansas in 1912 was \$6,258,726, as against \$5,864,822 in 1911.

Special Correspondence

PHILIPPINE ISLANDS

ANXIETY REGARDING GOVERNMENT POLICY.—ECONOMIC INDEPENDENCE MOST NEEDED.—DREDGING AT PARACALE.—MASBATE MINES.—BENGUET.

The new Governor General with his new policy (which is diametrically opposed to that of the past Republican administration), has now, in the middle of October, arrived. What ultimate effect the radical changes will have on the mining industry, it would be difficult to predict. The immediate effect is to depress stocks and to make capital exceedingly timid. There are enough uncertainties and drawbacks to the country, such as typhoons, labor troubles, distance from supply houses, etc., without adding the still worse features of possibility of unstable government and fear of confiscation of property. What capital has already experienced in Mexico, it has the right to expect here in tenfold degree. If the Filipino could but once realize that political independence must depend in large measure upon economic independence, and that they should foster legitimate mining in every way, there would be hope for those who have capital, energy, and trained knowledge. On the other hand, if these islands are turned into a political grab-

PARACALE DREDGING GROUND.

bag or into a political experiment station, then the 'jig is up.' It is to be hoped that the Filipinos of larger vision will be forthcoming to save what looks like a desperate situation.

During this week the well known local mining man, D. M. Carman, has returned with hydraulic machinery and an engineer, Mr. Shaw, for his property in the Cansuran district in the Surigao peninsula, Mindanao. In the Paracale district, Ambos Camarines, there are five dredges at work as follows: (1) the old Risdon dredge on the Malaguit river; (2) the old Stanley, or Maximilo, dredge on the headwaters of the Paracale river; (3) two dredges belonging to the Paracale Bucket Proprietary in the lower part of the river; and (4) the New York Engineering Co. dredge on the Gumaos river. One of the new dredges intended for operation on the Paracale river sank last May. The machinery is being recovered, but it will have to have a new pontoon. The Gumaos dredge, which had been digging rather successfully for a time, has had to put an extension of 25 ft. on the ladder to reach the 'pay.' Some anxiety has been felt by stockholders and it has been intimated that the Division of Mines of the Bureau of Science might be asked to make a thorough report. This has been proposed in Shanghai papers, in which city a good deal of the stock is held. The production of this dredge has fallen from nearly 2000 oz. per month to 220. The steel hull and machinery for the new dredge on the Umirai river has arrived in sections from Australia and is being set up.

In Masbate everything seems to be progressing satisfactorily. The new Keystone plant using Lane slow-speed mills has just begun operations. The Colorado mine and mill are reported to be running steadily. The Syndicate

mill is progressing toward completion. This mill will comprise crushers and Hardinge ball-mills, but will dispense with stamps. Renewed interest is being shown in the well known Benguet Consolidated property and it is possible that development will shortly be resumed there. The Headwaters mine has proved a complete fiasco and has given another black eye to the mining industry here. The Benguet district is now temporarily 'out of the running.'

The Division of Mines of the Bureau of Science has recently issued two press bulletins and a preliminary report on its findings in the Tayabas oilfield. The report is conservative and hints that those with limited capital should stay out of the field. It is rumored that two large companies have representatives on the ground investigating the possibilities. A new company consisting of Filipino capitalists has been organized to develop the Constancia property in the Angat iron district of Luzon.

PORCUPINE

HOLLINGER AND DOME REPORTS FOR SEPTEMBER.—PORCUPINE CROWN DEVELOPS SATISFACTORILY.—MCINTYRE, HOLLINGER RESERVE, AND JUPITER.

The report of the Hollinger gold mines for the four weeks ended October 7 shows gross profits for the period amounting to \$131,510. The mill ran 88% of the possible running time and treated 11,850 tons, of which 164 tons was for the Acme gold mines. The average value of the ore treated was \$17.39 per ton and an approximate extraction of 96.7% was obtained. Mining costs were \$2.94 per ton, and milling costs \$1.59 per ton. During the period, approximately 100 ft. of driving was done on the 425-ft. level of No. 1 vein, and the value of the ore and width of the vein indicate that there has been no falling off in either. Work has been started upon a winze which will be carried to the 550-ft. level. The report of the Dome mines for the month of September shows that 10,790 tons of ore was milled, which had a gross value of \$70,135. Good progress is being made with the addition to the mill, and the management expects to have the work completed in the early part of the new year. Recent development work on the Porcupine Crown property, which is controlled by the Crown Reserve Co. of Cobalt, has been satisfactory, and in the winze, which has been

sunk 60 ft. below the 400-ft. level, the vein shows an average value of \$80 per ton over a width of 5 ft. The general average of the mine, however, is in the neighborhood of \$22 over a stoping width and the management states that, to date, ore to the value of \$1,700,000 has been developed above the 400-ft. level. The clean-up from the 10-stamp mill in September returned bullion to the value of \$29,000, and with the addition to the mill in operation when the plant will have a total capacity of 100 tons per day, the earnings will be much greater. A new shaft is being sunk 1000 ft. south of the present workings, where ore has been proved at a depth of 300 ft. by means of diamond-drilling.

The September statement of the McIntyre mine shows that there was treated a total of 2786 tons of ore, from which was recovered bullion to the value of \$28,015. Total operating costs were \$28,127. This property suffers from long-distance mismanagement. The capacity of the mill is being increased, and it is expected that returns for October will be more satisfactory. The Hollinger Reserve mine is under option to the Lewisohns of New York and is now being developed by them. No details as to the terms of the option have been given out, but it is known that there were outstanding debts amounting to about \$50,000 which the Lewisohns paid, but which is a first charge against the property in the event of their not exercising their option. They are also to have the privilege of developing the property for six months before any payment of the purchase price is due.

The Jupiter mine was examined a short time ago by P. A. Robbins, the manager of the Hollinger, at the request of a number of the large shareholders. It is stated that his report did not bear out the figures given by the

Company's engineer. The Jupiter, which was being financed by the Drummonds of Montreal, has been closed for some time on account of their financial difficulties.

KALGOORLIE, WESTERN AUSTRALIA

HOWE PROCESS.—DEVELOPMENT OF THE ASSOCIATED NORTHERN CO.'S VICTORIOUS MINE.—IMPROVEMENTS AT THE CORINTHIAN NORTH.—AUGUST RETURNS.

After further expenditure of time and money, Ben Howe, manager of the Gwalia Consols, has had to admit that the success of his volatilization process of gold saving is as far from the realization of his dreams as ever. In June Mr. Howe stated to an interviewer that he was quite satisfied that, when he cleaned up the result of his continuous run of 60 hours, in which 45 tons was treated, he would get a theoretical return of 90%. Eventually, the return was published as \$187.60, equivalent to \$4.17 per ton. The assay-value of the ore was \$8.64, so that the extraction was only 50%, instead of the 90% predicted. Shareholders of the Company have been called upon to pay 2 cents per share to enable experiments to be continued. In connection with the volatilization of gold, I. H. Niemann, of Melbourne, claims that he has discovered that the presence of selenium in the ore causes gold to become easily volatile.

Malcolm Maclaren has completed his examination of the Great Fingall, Fenian, Ivanhoe, and Sons of Gwalia mines and has left for Queensland to report on the Great Fitzroy copper mine. Just before leaving Kalgoorlie, the directors of the Associated cabled instructions to Mr. Maclaren to report on that mine, and he will return here to do so. On his recommendation, the directors of the Ivanhoe are to continue sinking the shaft another 600 ft. to 3500 ft., at which depth Mr. Maclaren predicts that the porphyry bar and graphite, which impoverished the lode below the 2200-ft. level, will pass out of the ore channel to the west. Should Mr. Maclaren's prediction be fulfilled, the Ivanhoe directors intend prospecting the Ivanhoe Junction lease on the west, into which Mr. Maclaren asserts the quartz dolerite intrusion, which precipitated the gold, will dip at a depth of 2000 to 3000 feet.

Developments at No. 5 level of the Associated Northern Co.'s Victorious mine at Ora Banda have proved disappointing. Instead of the rich ore indicated by the winzes sunk below No. 4 level, the continuation of the ore-shoot at No. 5 level averaged only \$14.16 over a distance of 108 ft. The average value in the winzes was \$26.16 per ton, and the average depth 54 ft. or half way between the levels. Owing to the walls of the open-cut collapsing, there was a creep between No. 1 and No. 2 levels, and the Inspector of mines has prohibited any further working at those levels. Owing to this prohibition, the return for August only averaged \$4.58 per ton, and the profit fell to \$5000. No improvement in returns need be looked for till the first unit of the sulphide plant is in operation. The shaft was temporarily in jeopardy, but the inspector considers that the danger is now past.

F. W. Morgan, manager of the Bullfinch mine, died suddenly a week ago in the train on his way to Perth. Mr. Morgan had a large mining experience in New Zealand, and at Broken Hill, and from the latter field introduced the American system of square-set timbering on the Bullfinch. The metallurgist is temporarily in charge of the property. The complete plant is now at work, and when running smoothly is anticipated to treat 6000 tons per month of \$11 per ton ore at a profit of \$40,000 to \$45,000 per month. On January 1 the Company owed the bank \$180,000, but, up to the end of August, had earned a profit of \$246,000, and dividends may shortly be looked for. The No. 3 lode is still developing well at the 310-ft. level, and in a winze just started below that level the first 10 ft. sunk averages \$10.50 per ton.

The Ridgway filters on the Corinthian North are now in position and will be running next month, but the full capacity of 6000 tons per month is not expected at once. The ore recently developed is much better than it was at the time the Company was floated, when it was estimated to be worth \$6 per ton. Since the mill started, 10,983 tons

has been treated, yielding \$36,200, but the residue is estimated to contain \$56,800 more, making the ore worth \$8.46 per ton, or nearly 50% above the original estimate which appeared in the Company's prospectus. The lode on the Corinthian North is as much as 20 and 30 ft. wide, and has been proved by trenches and test pits for a distance of from 2000 to 3000 feet.

After drilling for nine months, the Government has only succeeded in putting down one bore-hole 1160 ft. and a second 610 ft. at Frasers mine at Southern Cross. The remaining bore-holes will be sunk by contract by the Goldfields Diamond Drilling Co. W. J. Loring, of the firm of Bewick, Moreing & Co., secured an option on the property before sailing for London early in May, and since then no results of the bore-hole developments have been published. However, it is hardly likely that contracts to continue boring would have been entered upon if the outlook were not promising. The ore-shoot on this property was mined for a distance of 4000 ft. with two small breaks above the 150-ft. level, but little development was done below that level, and the deepest shaft is only 375 ft., at which depth it has remained for over a dozen years. The gold recovered from treating 334,000 tons realized \$3,662,500, but costs were so high that shareholders received only \$238,700 in dividends.

The new wages agreement, which was made some time ago, was signed during the week. The agreement is fixed for a period of three years, from April 16, 1913, to April 15, 1916. As both sides are bound by penalties to adhere to the terms arranged, there should be three years of industrial peace.

MIAMI, ARIZONA

DEVELOPMENT AT THE CASTLE DOME PROPERTY.—PROGRESS AT THE BOSTON & SUPERIOR.—UNION REFUSES TO STRIKE AT MIAMI.—HEAVY FLOW OF WATER AT THE BOSTON COMMERCIAL.

At the Castle Dome property a second adit has been begun 100 ft. below the one in which rich ore was recently found. As in the workings above, a stringer of rich ore was found near the entrance of the adit and at present the entire face of the adit shows mineralization, which occurs as small stringers of high-grade ore in the form of chalcocite, chalcopyrite, and galena, and some gold and silver. On the extreme west end of the Duquesne property an adit has been driven 100 ft., and in the face the contact shows a strong quartz lead.

The vigorous régime at the Superior & Boston is bearing results, last month being the most prosperous month in the history of the mine, the shipments of more than four thousand tons to the El Paso smelter yielded returns well above all expenses. Raising has been started from the point on the 1000-ft. level where the ore was found in September. On the 800-ft. level a raise has been started 300 ft. east of the raise connecting the 800 and 600-ft. levels, through which the bulk of the mine's ore is now being extracted. The new raise is about 25 ft. high and will be continued until it reaches the stope level of the intermediate, where driving and stoping will be commenced. Diamond-drilling to explore the country east of the present workings was begun about the first of November and good progress is being made. At the Southwestern Miami, drilling is going on as usual. Hole No. 5 is 1170 ft. deep, and the casing is being pulled and the drill rig moved to the site of hole No. 18. Hole No. 16 is 883 ft. deep in the schist, and No. 17 is 468 ft. in the conglomerate. After the recent strike notice, issued by the Miami Industrial Council, the Miami carpenters' union refused to be governed by the action of the council and withdrew from that body, advising its members to return to their work at the Inspiration mill.

The Iron Cap property is in good condition. From present shipments it may be predicted that November's output will exceed that of October, which was considerably larger than that of the preceding month. The raise on the 800-ft. level has reached a height of 85 ft. The recent advent of water at the Arizona Commercial has temporarily checked the program of rapid development. The Company has not

given out any data as to its intentions regarding the increased pumping equipment that is to be installed. It is possible that by concreting the shaft considerable of the inconvenience caused by the flow would be obviated, especially on the 1200-ft. level, where the flow is at the rate of 100 gal. of water per minute. On the 700-ft. level driving has been discontinued and a raise has been started. Previous work at this point showed the vein to carry from a seam to 5 ft. of sulphide ore and the raise is in the nature of exploratory work to ascertain the possibility of the vein being of commercial value above the 700-ft. level. Driving on the 1000-ft. level continues east.

COBALT, ONTARIO

ARSENIC LIMIT AND SHORTAGE OF SMELTING CAPACITY.—
GOULD SHAREHOLDERS AND PETERSON LAKE.—ENERGITE
EXPLOSIVES ASSESSED DAMAGES.—NIPISSING STOCK.—
POWER SHORTAGE.

The recent decision of the A. S. & R. Co. to put a 7% arsenic limit on Cobalt ores, combined with the small capacity of the Canadian high-grade smelters, has resulted in a serious handicap to several of the mines. A very considerable proportion of the Cobalt ores carry in excess of 7% arsenic and several mines are now faced with the problem of marketing their product. Practically all the high-grade ore shipped from Cobalt was sent to the A. S. & R. smelter at Perth Amboy, the Pennsylvania plant at Carnegie, and to the Canadian smelters at Thorold, Deloro, Copper Cliff, and Orillia. During the past year, however, the smelters at Carnegie and Copper Cliff have been closed and the Orillia plant was destroyed by fire, while the other two Canadian smelters have only a limited capacity. The Deloro plant, which is controlled by M. J. O'Brien, gives preference to the ores from the O'Brien mine in Cobalt and the Miller Lake-O'Brien in Gowganda, and the remainder of the capacity is fairly well taken care of by the contracts already existing with other properties. The Thorold plant is owned by the Coniagas mine, and also has a contract with the Townsite mine, and has only a limited capacity in excess of the requirements of these two properties. It is understood that the Orillia plant will be rebuilt, and while this will relieve the situation to some extent, it will still leave a considerable tonnage of ore to be taken care of. Efforts are being made to develop a market in Saxony, where there are smelters for the treatment of ores similar to those in the Cobalt district, and which for some time have been running at reduced capacity on account of the failure of local ores. There is also some talk of erecting a customs plant at Cobalt, similar to those in operation at the Nipissing and Buffalo mines, where the high-grade ores are treated by a combined amalgamation and cyanide process, and where the results are claimed to be more satisfactory than can be obtained at the smelters. The output is in the form of silver bullion and the Cobalt residues find a ready market. The difficulty experienced in marketing ores is reflected in the shipments from the district for the week ended October 25, which constitute a low record since 1905.

On the 200-ft. level of the Gould property, a 2-in. vein of high-grade ore, which is the extension of the Worth vein on the Seneca-Superior lease, has been found. The original lease on this property from the Peterson Lake Mining Co., was transferred to the Gould Consolidated, which had a capital of \$3,000,000 in \$1 shares. When the funds of this Company were exhausted, the Porcupine Syndicate, with a capital of \$500,000, was formed to take over the lease. Last spring, the Porcupine Syndicate also ran short of money, and in order to carry on the work, \$20,000 worth of ore certificates were issued, redeemable for \$150,000, and constitute a first charge against the property. After the ore certificates have been redeemed and the operating expenses paid, the Porcupine Syndicate and the Gould Consolidated are each entitled to one-half of the proceeds. As the Peterson Lake Mining Co. receives a royalty of 25% of the gross value of all ore produced, it would appear that Gould shareholders are not in a particularly favorable position.

In a recent suit brought against the Energite Explosives

Co., whose plant was destroyed by an explosion a year ago, in which several lives were lost, one of the plaintiffs, a widow, was awarded \$3300 for herself and \$400 damages for her son, with costs against the defendants. There are also several other cases pending against the Company. The jury found the Company negligent on the following points: in not having the crushing room properly isolated from the mixing and finishing room; in not having confined the known dangerous operation of crushing compounds of sodium within properly constructed fireproof walls; and in permitting an unnecessarily large quantity of finished product to be stored in the finishing room where several employees were engaged.

During the first days of November the stock of the Nipissing Mining Co. experienced a considerable decline and fell from about \$9 per share to \$7.40. The action of the stock has given rise to a rumor that there is a possibility of the bonus being cut off when the next dividend is paid. At the present time Nipissing is paying 5% regular, with a 2½% bonus every quarter, which calls for a disbursement of \$1,800,000 per annum. According to the recent statements of the Company, however, there does not appear to have been any falling off in the earning power, and the cash surplus has been increased. The Temiskaming company has announced its intention of discontinuing the payment of dividends and also of stopping work on the North Dome property in Porcupine on account of insufficient finances. The financial statement as of September 30 shows cash in the bank and liquid assets of \$195,420. Development on the lower levels, however, has been very disappointing, and while several rich pockets of ore have been opened up, they are as a general rule of small extent and far apart, so that the cost of production is excessive. Owing to the dry summer and fall and the consequent shortage of water, the Northern Ontario Light & Power Co.'s plants at Matabitchouan and Ragged Chutes are short of power, and it has been found necessary to shut down the mills in the district in rotation for 24 hours each. It is believed, however, that this difficulty will be of short duration and that a little rain will give a sufficiency of power.

PLATTEVILLE, WISCONSIN

PRICES AND PRODUCTION.—MUCH ORE HELD IN BINS.—WORK
AT HIGHLAND RESUMED.—FIELD REPORTS A BIG FIND.—
MARSDEN BEGINS TO SHIP.

Fluctuating conditions marked the month of October in the Wisconsin zinc-lead field. While the production was equally as good as that reported for any month so far this year, only half of the active producers figured in the selling and shipping transactions for the month. For the first time in three years the price of zinc ore fell to a base under \$40 per ton for 60% standard ore. Leading operators attribute the decline to tariff changes. Low-grade producers are shipping just enough to meet their payrolls and operating expenses. Average prices for zinc ore for the month, supplied by one of the leading ore buyers in the field, obtained as follows: 30% concentrates, \$15 to \$16 per ton; 35%, \$17.50 to \$19; 40%, \$24 to \$25; 50%, \$26 to \$29; 55%, \$30 to \$35; 60%, \$39 to \$43.

Sales were made during the month as follows: to Mineral Point Zinc Co., 135 cars, 5033 tons; National Separating Co., Cuba, 41 cars, 1648 tons; Grasselli Chemical Co., Clarksburg, West Virginia, 40 cars, 1471 tons; Empire Roasting Co., Platteville, 33 cars, 1271 tons; Illinois Zinc Co., Peru, 18 cars roasted ore, 694 tons; Matthiessen & Hegeler Zinc Co., roasted ore, 16 cars, 313 tons; Linden Zinc Co., green ore, 17 cars, 470 tons; total, 300 cars, 10,900 tons.

Lead ore deliveries were light, because of reduced prices, much of the lead ore was held in bins at various points in the field at the close of the month. Shipments were made almost entirely to the Federal Lead Co. as follows: Saxe-Pollard, Linden, 54,450 lb.; B. M. & B. mine, Mifflin, 65,000 lb.; Milwaukee-Shullsburg, 55,706 lb.; N. H. Snow, 61,000 lb.; mixed lots, Linden, 63,400 lb.; Eddy mine, West Hanover, Illinois, 31,390 lb.; Northwestern Zinc Co., Day Siding, 80,000 lb.; total, 421,480 pounds.

Iron pyrite fell below the production reported for September, Linden shipping to Grasselli Chemical Co., East Chicago, Indiana, 688,520 lb.; National Separating Co., to General Chemical Co., Hegewisch, Illinois, 1,508,830 lb.; Wilkinson mine, Benton, to General Chemical Co., 634,600 lb.; to Grasselli Chemical Co., 1,917,400 lb.; total for all, 4,749,350 pounds.

Gross production of concentrates from mines for the month aggregated 10,253 tons; 'refined' ores and shipments direct to smelter of other ores, 6060 tons; the Mineral Point Zinc Co. delivered to its smelter from the roasting plant at Mineral Point 40 cars of high-grade spelter ore, 1470 tons. The stock of raw ore held in bins in the field is roughly estimated at 3000 tons.

The Mineral Point Zinc Co. has begun operations in the Kennedy mine at Highland after a six months' shut-down for alterations and improvements in the central power and milling plant. The C. M. & St. P. railway purchased the Mineral Point & Northern railway from the New Jersey Zinc Co.'s interests. At Platteville the West Hill Mining Co. found ore on lands adjoining the Big Jack mine. Drills penetrated ore on the Hill estate near the old Enterprise mine. The Klar-Piquette has found ore from its new shaft. The Vinegar Hill Zinc Co. has found ore on the Martin land and removed the Rowley mine equipment and rebuilt at this point. The Field Mining & Milling Co. has published results of drilling on the Thompson land; a body of zinc ore 1100 ft. long, 40 ft. thick, and from 100 to 160 ft. wide is reported. In the Galena district the Mineral Point Zinc Co. got started at the famous Black Jack or Marsden; the first two cars of zinc ore went to track the last week in October. In the Potosi district the Wilson Mining Co. began shipment of ore showing 58% concentrate. Extensive improvements were made here in the Preston Point equipment now doing service for the Wilson people.

NEW YORK

COPPER MARKET NEWS.—OCTOBER PRODUCTION.—GRANBY AT VALDEZ.—MASON VALLEY.—THE SOUTHWEST AND MEXICO.

The week that ended November 8 was disappointing to the copper interests. Share prices sagged badly under the debilitating influence of the decline in the London price of copper which, curiously enough, though largely speculative, has a stronger effect on the prices of copper shares than actual sales for consumption here exert. As the London price has dropped nearly £6 in the past couple of weeks, closing on November 7 at £69 12½s. spot and £68 15s. for futures, as compared with £75 and £74 7s. 6d. on October 23, the share market has gone down in sympathy. Of course such a movement is illogical, for the worth of shares is determined by dividend rates, which exhibit no such variations, but the ups and downs of share prices may be taken as speculation on the possibility of changes in the dividend rate. The figures for increased output are really entitled to an equal effect on share prices, since increased output means lower working costs and increased operating profits. Nearly all the companies are doing a rushing business in turning out copper. The Anaconda figures for October show a much smaller decrease than was expected from the shut-down at the beginning of the month to repair the flues at the Washoe smelting plant, and ore is now going to the plant at a record rate. The Mason Valley shows an increased output for October, and the Phelps-Dodge properties are turning out copper at a rate that will make their total for this year far exceed any preceding year. Utah Copper has shown a steady increase since July, Ray and Chino have been on the increase as compared with the early summer, while Miami's October yield was nearly a million pounds more than in May, when it was in trouble. There seems little prospect indeed of any 'copper famine' for a while yet.

The Granby is carrying on a vigorous campaign of exploration for good new properties, and has options on a number of mines in British Columbia. Not long ago the Midas mine, near Valdez, Alaska, was taken over on terms said to be very favorable. Good progress is being made in equipping the property, in which the ore is said to run 5% copper, and regular operation will probably begin next

summer. The Company has given up its option on the Mt. Andrew mine, on Prince of Wales island. This property was at one time under lease by the Britannia company, which failed to keep it. Excellent progress is being made at Anyox (Hidden Creek) and the Granby should soon be in a much stronger position.

The recent low price of Mason Valley shares is due, according to officials of the Company, to bear raids on the stock. The Mason Valley is in a somewhat peculiar position, in that it uses its mine as a regulator for the smelter. Besides its own ore it smelts that of the Nevada Douglas and a large number of smaller mines. Equal quantities of Mason Valley and Nevada Douglas ore make a fluxing mixture, and this does away with the necessity for using barren limestone as a flux. When the supply of Nevada Douglas ore is short, limestone is added to the charge, thus decreasing the output of the smelter. To keep smelting costs low it pays the Mason Valley company to decrease the output of its own mine when the supply of outside ore is short. Just now about 2500 tons per week is being sent to the smelter. The intelligent management which the Mason Valley has had is almost as great an asset as its ore reserves.

Philadelphia is proverbially inactive, but something has recently occurred there to galvanize into activity the Keane Wonder, and its shares advanced in a few days from 8 to 17c. The property is in Inyo county, California, not far from Rhyolite, Nevada, and has a 20-stamp mill; it is claimed that it has made an output of \$1,000,000 gross from medium-grade ore. The ore occurs in lenticular bodies along the contact between volcanics and schists, and carries a small amount of galena. The Butte-Duluth has started to enlarge its leaching plant to 1000 tons capacity, as drilling has proved the existence of considerable quantities of ore. It seems probable, however, that the management is not yet completely out of the woods in the study of its treatment problems. The Consolidated Arizona has arranged to build a 250-ton flotation plant in connection with its mill at Humboldt, Arizona. The Consolidated Arizona has been doing little more than mark time for years, since the frenzied whirls through which C. W. Morse and Thomas W. Lawson put it. Capitalized for \$17,500,000 in 1906, the working capital on hand in 1910 was stated at \$225,409. Some time ago the Company engaged A. S. Dwight as consulting engineer to straighten out its technical difficulties, but evidently found that the best of smelter experts cannot put ore into a mine. Everyone agrees that the plant is well situated to develop a good custom business, but the ore so far seems to have failed to come in. In the meantime the Inspiration 600-ton flotation plant is nearly completed, the Burro Mountain and the Old Dominion companies have signed contracts, and there is a wide interest in the process. The Nevada Consolidated made a poor showing in the third quarter of this year, reporting a deficit of \$95,000 between net earnings, and dividends and depreciation. The output of copper was 15,835,563 lb., an increase over the first quarter of the year, but a decrease as compared with the second quarter. This decrease was due to the lower grade of ore handled, 1.53% as compared with 1.76%, it being necessary to take ore during the autumn from the places which are less easy to work in winter. The cost of production went up to 10.09c. per pound, as compared to 8¼c. for last year. The stock of copper on hand and in transit is given as 22,000,000 lb., inventoried at 13.615c. per pound.

A note of optimism in the general Mexican gloom is sounded by the announcement that the dividend rate of the Lucky Tiger Combination, or El Tigre, is to be increased from 5 to 6c. monthly, corresponding to an annual dividend payment of \$515,043. Much is hoped from the new vein, called the Kelley, which was cut by diamond-drilling on the third level and which gives assays of \$500 per ton. Cross-cuts are being driven on the 100, 200, and 400-ft. levels, and it will soon be known how extensive the rich new discovery actually is.

Proposals to transfer the Bureau of Mines to the Department of Labor call out counter suggestions that a new Department of Agriculture and Mining be created to stimulate production of basal materials.

General Mining News

ALASKA

FAIRBANKS

At a recent meeting of the board of directors of the Newsboy Mining Co. it was announced that the property had shown a net profit for the month of September of \$2652, which is considered an extremely good showing. The total amount of the clean-up was \$8375.

TREADWELL

The report of the Alaska United Gold Mining Co. for the month of September presents the following statistics as to the work done by the Company during this period:

	R. B. Claim.	700 Claim.
Tons ore crushed	19,054.00	18,060.00
Tons concentrate saved	495.20	381.12
Estimated gross value of free gold...	\$25,115.20	\$23,839.46
Estimated gross value of concentrate.	21,083.64	20,250.94
Estimated total production	46,198.84	44,090.40
Estimated realizable value	45,736.86	43,649.50
Operating expenses	24,727.81	26,299.17
Estimated operating profit	21,009.05	17,350.33
Construction expenses, etc.....	5,180.08	1,923.43
Estimated net profit	15,828.97	15,426.90
Yield per ton of ore milled.....	2.42	2.44

The development work on the Ready Bullion Claim amounted to 122 ft., and that on the 700-Ft. Claim amounted to 440 feet.

VALDEZ

Reports from the Boston Consolidated Mines Co. indicate that the Company has had a successful summer. The work was somewhat impeded by the small hydraulic plant, which was not of sufficient size for the best results. The Company is planning to install two giant hydraulic plants next summer that will have a 36-in. flow of water. The plants this year were 10 in. smaller.

Announcement has been made that Moore creek, a tributary of the Kuskokwim river, is to be worked next summer by a giant dredge. The ground has been under examination for some time past, and the reports made on the property have been favorable. An order for the dredge has been placed, and it is expected that it will be constructed soon after the opening of navigation next year.

ARIZONA

GILA COUNTY

(Special Correspondence.)—The Miami Copper Co., during October, milled 91,613 tons of ore, and its copper production reached 2,956,952 lb. The additions to the crushing plant at the concentrator are working without a hitch, as is everything about the smoothly running plant. Underground, everything is being carried ahead at an even rate of progress, development on the Captain orebody amounting to 1126 ft. The Miami pipe-line from Burch pumping station to the Miami mill was recently changed because of the evil effects feared from vibration from trains traveling above it on the Inspiration line. Concrete is being placed at the lower tailing dam, but with few minor exceptions there is nothing unusual in the way of new work at the property.

Miami, November 7.

Excavation is now well under way for the power-house which the Inspiration Consolidated Copper Co. is to build in Webster guich. Work is now moving along evenly, all steel being in place for about two-thirds the length of the bins, which will be completed within a short time. Steel for the crushing plant will shortly arrive, and work will be started on this next, in conjunction with the head-frames for the main shafts. Within a few weeks the new test-mill will be ready for operation, as practically all the machinery is now in place and the crushing plant at the Scorpion shaft is almost completed. Work underground is moving along as well as can be expected. The recent cave-in in the West Main shaft was no more than was expected by the Company, and everything was in

readiness to care for it. No doubt this shaft will be concreted, and then there will be no further trouble along this line. New headings are still being started, and within a short time the Company will be mining ore to supply the new test-mill.

MOHAVE COUNTY

The California Nevada Exploration properties near Chloride, Arizona, are idle at present. Two shipments are said to have been made to the smelter at Needles, and the returns are said to have netted \$1350. Considerable work has been done on a number of claims, and there is a gasoline hoist and other equipment available.

YAVAPAI COUNTY

The smelter that is being constructed by the United Verde company at Clarksdale will be one of the most complete plants for the smelting and refining of ores in the United

MAP OF ARIZONA.

States. This plant when completed will cost over \$6,000,000 and will have an initial capacity of 2500 tons per day, or more than twice the capacity of the Company's smelter at Jerome. The smelter equipment of the Clarkdale plant will consist of six roasting furnaces, three 19 by 100-ft. reverberatory furnaces, four 48 by 32-in. blast-furnaces, and four Allis-Chalmers 12-ft. upright basic converters. The smelter site is on a branch of the Verde at an elevation of 2400 ft., which is sufficiently high above the river to afford ample dumping ground for slag. The main shaft of the mine is connected at a depth of 100 ft. by a tunnel with the smelter. All of the ore from the mine will be transported to the smelter through this tunnel.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—The Oro Water, Light & Power Co. is prospecting gold-bearing gravel with a Key-stone drill, on the Amador county side of the Mokelumne river, about two miles below the Penn mine. The Company's dredge, with 9-cu. ft. buckets, is handling 160,000 cu. yd. of gravel per month at Camanche, about five miles from Campo Seco, on the Calaveras side of the river. Electric power is used for all purposes on the boat.

Camanche, November 9.

(Special Correspondence.)—On No. 36 level of the Kennedy mine, the cross-cut has just entered a new ore-shoot, the hanging wall of which is a graphitic slate. Between No. 33 and 36 levels stoping is being done on a wide vein, in one place there being 15 ft. of solid quartz. Generally, the mine is in a healthy condition. Construction of the

wheels, to elevate the tailing from the mill over to some ground bought by the Company is proceeding at a good rate, and Webb Smith, the manager, expects this to be nearly complete in 30 days. At the Zeila, only 20 to 25 stamps of the 40 in the mill are working. The future scope of operations has not been decided upon yet.

Jackson, November 11.

(Special Correspondence.)—Work at the Plymouth has been reduced, temporarily, to a minimum, and but few men are working. The special funds set aside for development have been largely spent, and with such encouraging results that W. J. Loring has returned to London to make arrangements for operating the mine. In the meantime, advance work underground has been suspended and Gelasio Caetani is preparing plans for a new mill.

Plymouth, November 11.

CALAVERAS COUNTY

(Special Correspondence.)—The three dredges here have been shut down since October 16 on account of shortage of water in the Calaveras river. The recent rains have not been sufficient to float them. One boat is of 3.25-cu. ft. bucket capacity and has been handling about 50,000 cu. yd. of gravel per month, while the other two, with 6-cu. ft. buckets, have turned over from 60,000 to 80,000 cu. yd. each per month.

Jenny Lind, November 7.

(Special Correspondence.)—At present the Calaveras Copper Co.'s mine, concentrating plant, and smelter are shut down, pending payment of debts in Stockton and other places and a practical reorganization of the Company. The property is reported to have been badly mismanaged, but is now in charge of J. G. Hadley who has only a small staff with him. Shipments of concentrate to the Selby smelter have been made until recently from stocks at the mill, but there is a shortage of water preventing further ore treatment. The mine is opened to 1000-ft. depth, and on this level some rich copper ore has been opened, and the property itself is said to be good. There is over 50,000 tons of 3% ore reported on the dumps ready for milling. The reverberatory furnace that was erected was a complete failure. The property is situated 16 miles by stage from Milton, the terminus of the railroad from Stockton, and in the winter transport of freight is difficult, so in all probability the mine will not be reopened until next spring. Boston people are interested in the Company.

Copperopolis, November 7.

MERCED COUNTY

(Special Correspondence.)—With a view to continuing its operations when the present area of ground is worked out, the Yosemite Dredging & Mining Co. is prospecting some gravel from two to three miles from Snelling. A Keystone No. 3 drill is used, and the work is being done in a systematic manner. J. H. White is manager.

Snelling, November 6.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—There was a gain of 66% in tonnage for the month of October over that of September, while the local sampler paid out \$47,000 for ore. The principal part of the product came from the Gem, Little Mattie, and Specie Payment mines. John Peterson, leasing on the Silver Age mine on Seaton mountain, is marketing smelting and concentrating ore. The first-class is worth \$60 per ton. Another contract for 100 ft. of driving will be awarded by the Honest John M. M. & T. Co. during the next few days. The adit is now in 2150 ft. The Pozo-Gilpin mine is being developed through the New-house adit. At present about 1000 tons of ore is being extracted each month.

Idaho Springs, November 5.

GILPIN COUNTY

The shaft on the East Notaway property of the Square Deal Mining Co. has reached a depth of 870 ft. and will be continued 90 ft. deeper before the work of cross-cutting to the vein is commenced. A station is being cut on the 850-ft. level. Several good shipments have recently been made from this property to the Globe smelter.

TELLER COUNTY

An electric hoist is about to be installed on the 1100-ft. level of the American Eagle property of the Stratton estate. A review of the Vindicator Consolidated Gold Mining Co.'s operations for the past quarter is of particular interest from the statement that the drifts in the 1600-ft. or present deepest level in the main or Vindicator No. 1 shaft have been carried to such a length as to warrant the assertion that these drifts indicate a lengthening of the ore-shoots. Stockholders have been advised that the Company is making preparations to deepen its main shaft an additional 200 feet.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.)—A joint meeting of the Spokane and Montana local sections of the American Institute of Mining Engineers will be held at Wallace, Idaho, November 15 and 16. A train will leave Spokane at 8:40 a.m., Saturday, November 15, arriving at Wallace at 12:50 p.m. The afternoon and evening will be devoted to the reading and discussion of papers, and to the election of members to the executive committee of the Spokane local section. It is proposed to change the name of the Spokane local section to Columbia local section as more representative of the area covered by the organization. Sunday, November 16, will be occupied in visiting mines and mills, this portion of the program being in the hands of a local committee of which J. F. McCarthy is chairman. A smoker will be held Sunday evening and the visiting members will return home Monday morning, November 17.

Spokane, Washington, November 1.

One of the most important Coeur d'Alene mining deals consummated recently is the bond and lease taken by the Idora Hill Mining Co. on the property of the Tuscumbia Mining Co. at a price of \$225,000. Not all of the stock of the Tuscumbia was covered by the present option, but enough to give the Idora company working control of the property. The consolidation of the two companies is of great advantage to the stockholders and promises greater convenience in working them. The Idora is equipped with a mill, which is running steadily on ores taken from the Idora, but with the addition of the Tuscumbia, which is in shape for immediate production, the mill can be run to its capacity and the shipments of ore correspondingly increased.

The Interstate company, in Nine Mile cañon, in the Coeur d'Alene, is equipping the mine with electric haulage for a distance of 4000 ft. The milling plant is now running at its full capacity of 300 tons per day. Five 4-horse teams are busy hauling the crude ore and concentrate to Bunn station, the shipping point. Work is also progressing on the construction of 12 new hungalows and a 75-room hotel for employees. All buildings will be equipped with steam heat, baths, and all modern improvements.

The H. E. & M. company is considering a plan to erect a concentration plant near the mine on the Coeur d'Alene river. The Company recently started a new lower tunnel, which will furnish a means of delivering the ore direct to the new mill. The orebody has been opened by three tunnels and enough ore blocked out to warrant the erection of a milling plant. Several cars of the ore have been shipped crude under leases.

CUSTER COUNTY

The Empire Copper Co. is working about 150 miners at the present and the property is being worked at 32 different points. The showing throughout the property is very satisfactory and it is expected that the production for the present year will greatly exceed that of last year.

MICHIGAN

HOUGHTON COUNTY

Four months after the commencement of the strike in the local copper mines, finds the Calumet & Hecla company producing its normal tonnage of 'rock.' The last week of October the rock tonnage was increased to 7300 tons per day, within 1000 tons of the average before the strike

started. The Calumet & Hecla does not now need any further additions to its underground working forces. The new trammers are better, on the average, than the workmen who continue to strike, in that they can do better work and less time is required to oversee their operations as they understand instructions in English. While the other mining companies have not succeeded as well as the Calumet & Hecla, tonnages at all of them have shown steady increase, and some of the subsidiaries are now running about normal. Superior made a shipment November 1 of 50 tons of rock, and on Monday of 450 tons. This is a remarkably good showing. The Copper Range Consolidated mines, Trimountain, Baltic, and Champion are operating short handed. F. W. Denton held off longer than any of the other mine managers before sending outside for trammers and miners. He was particularly anxious to give all of his old employees the first chances at the jobs, feeling that they were unfortunately misled into the strike and that should not be made to suffer. However, the Copper Range received large additions to the working forces this week. Most of these men came from Chicago, where the steel plants are laying off men rapidly. A few are coming from the iron mines of the Crystal Falls district, where they are suspending operations at some of the mines and curtailing forces at some others.

At the Naumkeag and the Phoenix shaft-sinking is in progress. At the Naumkeag the exploration shaft is down and the first cross-cut well advanced. Both the shaft and the cross-cut are in the ore formation. It is not, however, showing any remarkable richness in copper content. At the Phoenix property of the Keweenaw Copper Co. a temporary hoist is in operation while the permanent hoist, removed from the Mandan, is being erected. A force of 25 men is employed.

The operations on the White Pine property, a Calumet & Hecla subsidiary, in Ontonagon county, continue to be satisfactory. Two shafts are in use and a third will be working before long, as the underground openings, including an upraise, have been extended. The Nonesuch lode continues to show commercial copper in the lower workings. The lode is narrow, but unusually rich, and the probability of securing a substantial amount of copper is not doubted. There has been no interference with the operations at this mine because of the strike.

MISSOURI

JASPER COUNTY

Incorporation papers have been issued by the Secretary of State for the organization of the Kentucky Lead & Zinc Co. of Joplin. The capital stock of the Company is \$1,000,000. Preparations are being made to conduct extensive mining operations on the Chitwood property. A mill will be moved to the property and be in operation within the next few weeks. A good tonnage of ore has been developed, and is ready to be milled.

The Investors' Realty Co. recently purchased thirty acres of ground from the Queen City Lead & Zinc Co. The ground is considered most desirable property. It is understood that development work will be started at once.

A second shaft is being sunk on the Snapp property at Thoms station. The ore which has been mined has shown a recovery of 10% zinc. Several drifts have been made in the formation at a depth of 177 ft. which are all in ore. The ground is soft and requires much timbering.

The Imperial mill, which is being operated by the firm of Weeks & Briggles on the Kelly property to the north of Webb City is producing a large weekly tonnage of both lead and zinc concentrate. The ground which is being worked contains two sheet formations, one at a depth of 165 ft., which is from 12 to 15 ft. thick, and the other at a depth of 182 ft., which is 12 ft. thick.

Unless the large pumping plant at the Providence mine in the district north of Webb City is kept in operation, fear is expressed that a large part of the mines of that district will be flooded due to the rising waters in the old Yellow Dog mine. The water will affect 17 of the largest mines in the district. At present the pumping plant at the Providence is draining this ground, and as no remuneration is being received for this work, the Providence com-

pany is reported to be about to close down the pumping plant unless the mines which are being drained by this plant will pay a part of the operating expense. The danger from water began when the Underwriters Land Co. closed down the Yellow Dog mine. The pumping plant at that mine discharged 3000 gal. of water per minute and the water was kept below the level where mining operations were conducted. When the big pumps were taken out and the land abandoned the water gradually began rising in the drifts until the underground workings of the Yellow Dog mine are a great lake, covering forty acres of land. The water has risen and overflowed the abandoned drifts on other tracts of land north of Webb City and has now reached a sufficient height to endanger every mine in that part of the district.

A new discovery was recently made by O. W. Sparks, 300 ft. to the east of the Yellow Pup mine. The new shaft is above the plant at the Yellow Pup mine and a tramway has been completed from the shaft to the mill. Ore is run to the hopper by gravity and it is only necessary to haul the empty cars back up the hill. The tramway is about 300 ft. long. The new deposit of ore is said to be richer and thicker than those being worked at the Yellow Jacket and Yellow Pup mines. Apparently, the run of ore in the new shaft covers a wide area and that being taken from the drifts shows a good grade and is not penalized, from the two mines is of high iron and the metallic content always is above 60%, sometimes running as high as 63%. There is a 200-ton mill at the mine. During the past few months considerable development work has been done at both mines and some new ground has been opened.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—The Anaconda Copper Mining Co. is making preparations to reopen the shaft on the Philadelphia group in the West Butte district. During the past week four large boilers have been transported to the property and numerous buildings have been built on the surface. It is proposed to sink the shaft, from its present level of 450 ft., to a depth of 2000 ft. This will develop one old silver belt on which not much work has been done since the closing of the old Blue Bird mine in the nineties. At that time some 20,000 tons of silver ore from the Nettie was milled in the old Colorado mill, but owing to the fact that a great deal of the silver mineral floated in the slime, a recovery of a little better than 50% of the silver content was the best that could be made by concentration. A process of double concentration and cyanidation has since been developed by John E. Rothwell and Carl J. Trauerman and experimented with in the Butte Central mill. By this process it is possible to treat the silver ores of the West Butte district and make a recovery of practically all of the gold and 85% of the silver at a small treatment cost. This treatment has been claimed to be successful even in the presence of 30% zinc and 2% copper, when in the shape of sulphides. It is possible that the reopening of the Nettie, together with the successful working out of the process to recover the gold, silver, copper, and zinc from these ores will mean the rejuvenation of some of the old silver mines of Butte, such as the Lexington, Spruce, Travona, Little Darling, Blue Bird, and Germania. A great many options have lately been taken in this district on properties to the north of the Nettie, and it is said that a company to take over these options and reopen the mines has been formed by ex-Governor McDowell of Montana.

Butte, Montana, November 8.

A reorganization of the Butte Central company is under way in Boston. Plans have been submitted which are said to have been accepted by the principal interests in the Company, and the revamping of the enterprise is assured. The capitalization of the new Company will probably be about \$750,000. It will start business, apparently, with all the overhanging indebtedness cleaned up, some money in the treasury, a splendid type of mill, and a mine opened up to the 500-ft. level. At last accounts it was

understood that the basis of reopening the property would be the operation of the new mill, built by John E. Rothwell, as a custom plant for the concentration of Butte argentiferous ores, and the mine would be worked by lessees for the present, the earnings from these two sources to be used in developing the property below the 500-ft. level, as the prospects of finding copper are considered good by practically all the engineers who have made examinations. The presence of the Rarus fault zone at the 500-ft. level has occasioned some dispute as to upon which side of the fault the orebody occurs.

MADISON COUNTY

The Idaho Development Co. is prospecting the placer property of the Alder Gulch Consolidated Mining Co., situated in Alder gulch near Virginia City. A drilling machine is working under direction of E. A. Thurston.

NEVADA

ESMERALDA COUNTY

The estimated October production of the Goldfield Consolidated Mines Co. is as follows:

Total tons mined	30,483
Gross value recovered	\$337,000
Operating expenses	183,000
Net realization for month	154,000

Work has been suspended in the 509 drift on the 500-ft. level of the Hornsilver Mining Co. because of a lack of timbers. The vein at this point is 24 ft. wide and contains about two feet of milling ore. The ore which has been developed on the 300-ft. level has shown some good assays, although the average assay shows that it will be difficult to stope ore of a milling grade. A winze was sunk from this level for a depth of 51 ft., but has failed to develop ore of a shipping grade, the average assay being about \$6 per ton. Work on the 303 drift has developed a good grade of ore, some of it assaying as high as \$38 per ton; this ore, however, occurs in pockets. While the work, to date, has yielded no direct results in the way of smelter returns, Weldon B. Morris, the general superintendent, is hopeful and believes that the present outlook is encouraging.

The Nevada Wonder Mining Co. recently declared a dividend of 10c. per share, which is the second to be paid by the Company. The Company has been operated on a profit-making basis for the past year. Announcement has been made that dividends will be paid semi-annually in the future. The Company is making regular shipments of bullion to the mint.

LINCOLN COUNTY

The Amalgamated Pioche Mines & Smelter Corporation has shipped 70 cars of ore, since last August, having a value of about \$25,000. A number of improvements are being made, and there is ample evidence that the owners of the property have faith in its future.

LYON COUNTY

It is reported that no dividend will be declared this year on the shares of the Mason Valley Mines Co. The Company is shipping from 2000 to 2500 tons of ore per week, and the development work which is being done is putting in sight more ore than is being shipped. It is believed that the report for this year will show that large profits have been earned.

The last round of holes shot in the face of the Ludwig 8th level of the Nevada-Douglas property broke into ore running 10.4% copper. This ore is a secondary chalcocite mixed with about an equal amount of native copper in a sugar quartz gangue. It means that the 8th level is in the zone of secondary enrichment; that the primary ores have not yet been encountered, and that from the 800 to the 700-ft. level the ore is of about the same character and richness as on the 700-ft. level.

On Douglas hill a drift has been started from the Iowa raise toward the Orem winze. This drift is 25 ft. below the Douglas tunnel level and is in 50 ft. in ore, and with the present face showing ore running 5% copper. As this ore dips down and toward the Orem winze, a drift has been started which will cut it on its dip. The production

of copper for the month of September was 426,101.97 lb., which at 16 $\frac{3}{4}$ c. per pound (the present selling price of the metal) shows a gross income of \$71,371.91 for the month. The month also shows a gain in the gross income of \$10,941.21 over the month of August.

NYE COUNTY

The new orebody which was recently opened on the 600-ft. level of the Tonopah Mining Co.'s property gives promise of becoming a good producer. The vein was encountered in a south cross-cut from the end of the southwest drift of the Mizpah shaft in the Valley View claim and close to the eastern boundary of the West End mine.

It has been announced that the Jim Butler company will begin sinking the Wandering Boy shaft from the seventh to the eighth level and develop the orebodies which are known to exist at this depth. It is also proposed to start a north cross-cut from this level for the purpose of cutting the extension of the new orebody which has been exposed by the Tonopah Mining Co. in the Valley View claim. It is believed that this vein enters the Jim Butler property at a depth of from 700 to 800 ft. The Company is also planning to cross-cut from the Desert Queen shaft on the South vein of the Tonopah Mining Co. up to the Jim Butler boundary line. In the Desert Queen mine, from the 700-ft. level to the 1000-ft. level, the ore was from 4 to 8 ft. wide and of good grade, and there is therefore every reason to believe that a good grade of ore will be opened from the same vein on the Jim Butler property.

Development work on the 400-ft. level of the Tonopah Extension property has resulted in opening what is believed to be the western extension of the North Vein, which has now been penetrated for a distance of seven feet without finding the foot-wall. The vein occurs in a trachyte formation, and it is estimated that it will only be necessary to do about 50 ft. of cross-cutting from the main west drift of the mine to open it on the 500-ft. level, which work will be commenced immediately. Another important development in the property was in stope 51-6 west, on the 500-ft. level, where on the hanging wall of the stope a splendid body of ore, 6 ft. wide, has been broken into. The full extent of this orebody is not yet known, as the metal extends into the hanging wall formation of the vein and sufficient exploration of the vein has not yet been done to determine the full width of the ore. Development from the new main working shaft continues to be most satisfactory.

WHITE PINE COUNTY

A new company has been organized, which is known as the Silver Mining & Leasing Co., to operate in the White Pine district. The Company has purchased the Zadow group in Rocco cañon. A good production from one of these claims was made a number of years ago. The development work consists of a shaft 265 ft. deep, from the bottom of which a drift was run for a distance of 100 ft. This drift will be continued, as it is believed to be within 50 ft. of one of the principal ore-bearing fissures.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—Four bars of bullion were expressed to the mint last week from the Deadwood mines. Ore treated during the period was 380 tons. A regular daily shipment of 40 tons from the Little Charlie mine to the custom mill has been maintained for the past two months. A large ore reserve has been developed. The property is owned by the Mogollon Gold & Copper Co. and operated by a Los Angeles firm of lessees which also holds a bond to purchase. The Pacific Mines Co. is shipping 25 tons of ore per day to custom works. Development in the mine is quite encouraging and the ore reserves are increasing. The electrical equipment purchased several months ago is being installed. Lessees of The Oaks Co. have sunk B winze in the East End tunnel group 25 ft., obtaining approximately 26 tons of ore from same. An additional 25 ft. will be sunk, after which stoping will be commenced. During October, 33 bars of bullion, weighing approximately 1 $\frac{3}{4}$ tons, were shipped to the mint from the Socorro Mining & Milling Co. and a large

amount of concentrate was sent to the smelter. The ore treated was about 5400 tons for the month. The deepest heading in the mines, 900 ft., continues to yield a good grade of mill ore; occasional pockets of high grade are encountered. An auxiliary water-supply has been established at the Ernestine Mining Co. by sinking a well in the cañon about one-half mile from the mill and installing an electric pump. Sinking of the main shaft is progressing nicely. The mill is now treating from 160 to 175 tons of ore per day.

Mogollon, November 3.

OREGON

JOSEPHINE COUNTY

(Special Correspondence.)—The winter rains have started a number of the hydraulic placers. Thomas Wilson, of Nevada, has bought the Grand Prize placer, of Sucker Creek district, discovered by T. M. Anderson last February. The price to be paid is \$100,000, of which a substantial part was handed over; Mr. Anderson to retain one-fourth the net profits of the mine till settlement is made in full. The Grand Prize is in a dry gulch well up on the Siskiyou, near the California line. There being no water available, Mr. Anderson has followed the plan of packing the dirt by burro down the mountain over a rough trail to the nearest stream. It has yielded average returns of \$25 per yard. The deposit is reported 200 ft. wide and over 1500 ft. long, and has been opened to a depth of 200 ft. The new owner has already begun the placing of hydraulic equipment and will operate one or two giants with water brought from Lake creek. The Almeda smelter, on Rogue river, near Galice, has managed to keep in operation for some time by running a line of motor trucks between the property and the Beaver cement plant, near Gold Hill. Each truck makes a round trip every day, hauling a load of lime to the smelter, and on the outward trip taking a load of matte as far as Merlin, where it is loaded on the cars for shipment.

Grants Pass, November 8.

UTAH

SALT LAKE COUNTY

A meeting of capitalists from various parts of the United States and Canada was recently held in Salt Lake City for the purpose of formulating plans for the development of the iron and coal deposits of Utah and the establishment of a large steel plant at San Diego. An extensive report of the coal and iron resources of the Colorado river basin has been made by R. E. Clapp and the properties will be selected by Julian Kennedy of Pittsburgh. Details have not as yet been made public, but it is believed that a great impetus is about to be given to the coal and iron industry of Utah.

CANADA

BRITISH COLUMBIA

Plans have been perfected by the Hedley Gold Mining Co. for a power development on the Similkameen river. The scheme comprises a concrete dam on the river a little below the mouth of Twenty-mile, with a head-gate on the north bank of the river leading into a flume which will extend down the river for 1800 ft. to a bridge and viaduct which will carry the flume across to the other side of the river. For this flume about a million and a half feet of lumber will be required and the cement used in the dam and at the power-house will likely total about 3000 bbl. Electricity will be generated at 6600 volts and will supply a 1500-hp. unit. While no scheme for enlargement of the mill has yet been decided on, it is generally believed that work for increasing the capacity of the mill by at least 50% will be commenced soon.

ONTARIO

(Special Correspondence.)—Nothing of particular importance has been developed in the Swastika district during the past few weeks and conditions are less encouraging. The Swastika mine has been reopened, but it is not believed this will lead to anything except further loss of money to those who are financing the property. The Burnside mine in Kirkland Lake has been closed and it is stated that lack of funds is responsible for the cessation

of work. C. A. Foster has gone to London with the object, it is believed, of disposing of the Tough-Oakes property. No information is as yet available, however, regarding this.

Swastika, November 5.

The report of the Buffalo Mines, Ltd., for the month of September shows the following:

Mill ran, hours	605½
Ore milled, tons	5,744
Average assay per ton before milling, ounces....	20.83
Silver recovered, ounces	99,043.00
Silver paid for during month, ounces.....	207,054.00

The ore treated during August and September came from old stock-piles. Dividends No. 53 of 5% and No. 54 of 15% were paid on October 1. The total dividends which have been paid amount to \$2,437,000.

MEXICO

SONORA

Sinking is progressing well at the Calumet & Sonora mine, northwest of Cananea. The dry mill is treating old concentrate, and the wet mill is closed at present. La Cobriza Mining Co. is to resume work at its mine and smelter west of Noria. The Moctezuma Copper Co. will develop its Churuniabahi mine, near Nacozari, until recently leased by Norton Hand. The Santa Rosa, east of Cabullona, has been leased to J. E. Englent and H. F. Brown.

NICARAGUA

During September, 1790 tons of ore yielding \$12,000 was treated at the Oroya Leonesa mine. The west drift, 105 ft. below No. 1 adit was extended 39 ft., averaging \$10.20 in gold and 63c. per ton in silver.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

B. L. THANE is down from Juneau.

RENE E. HAZARD is now at Angers, France.

JAMES PARKS was in San Francisco this week.

ERROLL MACBOYLE was in San Francisco over Sunday.

W. H. RADFORD has gone to Oregon to examine property.

W. J. PATTERSON has returned from a trip through Nevada.

DESAIN B. MYERS will be at Nevada City until November 21.

N. H. RUBY came up from Durango by way of Mazatlan last week.

WARREN D. SMITH has returned to Manila from a trip through China.

GEORGE A. PACKARD has left Butte for Boston, where he will be for some weeks.

F. DANVERS POWER is in San Francisco on his way from the Malay States to London.

HOWARD M. BLACK, of Grass Valley, is examining mines near Crested Butte, Colorado.

HUNTINGTON ADAMS has gone to New York City, where his address is 115 East 80th street.

JAMES IRVING examined the 'Star of the West' mine in Inyo county, California, last week.

ARTHUR WINSLOW is in the hospital recovering from the effects of an operation. He is doing nicely.

FRANK H. PROBERT passed through San Francisco this week, going from Plumas county to Los Angeles.

G. D. KISLINGBURY has come up to Los Angeles from Rosario, the inability to get supplies having forced the closing of the Minas del Tajo.

GEORGE H. GARREY, chief geologist for the American Smelting & Refining Co., is considering opening an office for consulting work in San Francisco.

THE UNITED STATES CIVIL SERVICE COMMISSION announces a competitive examination for positions as oil and gas inspector for the Bureau of Mines. Salary \$1800 to \$2500.

M. L. JANDORF, who has been studying the limestones of York county for the Pennsylvania Geological Survey, has taken the position of process foreman for the Standard Chemical Co. at Canonsburg, Pennsylvania.

The Metal Markets

LOCAL METAL PRICES			
San Francisco, November 13.			
Antimony.....	10-10½c	Quicksilver (flask)	\$39
Electrolytic copper.....	17½-17¾c	Tin.....	44-45½c
Pig lead.....	4 60-5.55c	Spelter.....	7-7½c
Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.			

EASTERN METAL MARKETS.
(By wire from New York.)
NEW YORK, November 13.—The copper market is weak and a general decline is to be noted in copper stocks. Lead and spelter are dull and but few sales have been reported. The London copper market is slightly firmer, with spot quoted at £58 and futures at £67 10s. Antimony is dull, with Cookson's quotation at 7.60c. Tin is firm, with spot at 39.37½ to 39.62½. China is at present on the selling side of the silver market. India has made its purchases for the time being and financial difficulties at Bombay have caused a further easing of the market.

SILVER

May	16.03	15.42	Nov.	17.31
June	17.23	14.71	Dec.	17.37

The copper market weakened last week, and with the publication of the Copper Producers' figures, on November 7, showing an increase of 2,700,000 lb. in stocks, the market remained dull. "Second-hand" copper was available at 16¼c., but little business was being done. The visible supply in England, France, and afloat on November 1 was given as 21,380 tons, a decrease of 584 tons, in two weeks, while the German stocks were given at 4476 tons, a decline of 366 tons since October 15. The London market has been steadily weakening, showing a decline of £6 10s. per ton in the past two weeks.

The German consumption of foreign copper for the first

seven months of the year, according to L. Vogelstein & Co., was as follows:

	Tons.
Imports of copper	153,354
Exports of copper	6,584

Consumption of copper146,770
This may be compared with a consumption of 136,411 tons for the same period in 1912. Of the above quantity, 132,425 tons was imported from the United States.

ZINC			
Zinc is quoted as spelter, standard Western brands St. Louis delivery, in cents per pound.			
Date.		Average week ending	
Nov. 6.....	5.09	Oct. 1.....	5.39
" 7.....	5.09	" 8.....	5.24

May	6.68	5.23	Nov.	7.23
June	6.88	5.00	Dec.	7.09

Straits shipments in October were about the same as in September, and the visible supply on November 1 was 11,857 tons, a decrease of about 1000 tons as compared with last year. As a result, the market was firmer. Contracts for tin plate for 1914 are all being made on the basis of \$3.40 per base box, which corresponds to a reduction in price of \$2 per ton.

QUICKSILVER
The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending		Oct. 29.....	40.00
Oct. 15.....	39.00	Nov. 5.....	39.00
" 22.....	39.00	" 12.....	39.00

June	45.76	45.10	Dec.	49.80	...

Copper

According to L. Vogelstein & Co., copper has shown great firmness during the recent dull period, owing in large part to the strong statistical position of the metal. It seems impossible that during a period when complaints as to the volume of business have been so universal, the consumption of copper, both here and abroad, should have exceeded that of any previous year. Such excess consumption to the end of September amounted to almost 100,000,000 lb. as compared with last year, while the production increased approximately only half that amount. Hence last year's 26,000,000 lb. decrease of domestic stocks January to September, has this year jumped to a decrease of 76,000,000 lb. The results over a period of years make the following remarkable showing—foreign and domestic stocks included:

	Pounds.
On hand September 30, 1911.....	311,392,456
1912.....	154,614,387
1913.....	81,568,454

Copper Producers' Association Report

The Copper Producers' Association statement, November 7, shows an increase in production and stocks on hand. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, October 1, 1913.....	29,793,094
Production of marketable copper in the United States from all domestic and foreign sources during October.....	139,070,481

The Aluminum Industry

The report recently issued by the Aluminum Industrie Gesellschaft, which owns the large works at Neubausen, Switzerland, shows net profits for the year of \$717,000, against \$448,000 in 1911, and dividends were 20%, against 14% in 1911. The very low prices of aluminum which prevailed for some time resulted in many new uses being found for aluminum, which favorably influenced the development of the industry and enabled the whole Swiss production to go into consumption. As to the aluminum industry in the United States, it may be said that the market during the latter part of 1912 was brisk; later the demand has exceeded the supply. The Aluminum Company of America has been making serious efforts for some time past to increase its production, but has been confronted with difficulties in securing an adequate source of supply of electric power. It has, however, secured certain riparian rights in North Carolina and Tennessee. The development of this water-power is contemplated. Until its own power development is completed, the Company will use power supplied by the Tennessee Power Co. from its development on the Ocoee river, near Chattanooga; this new aluminum plant will, it is planned, be in operation by the latter part of 1913.

Monthly Copper Production

AHMEEK COPPER MINING CO., Kearsarge, Michigan. \$1,250,000 in \$25 shares; 24,796 shares owned by Calumet & Hecla; 1800-ton mill at Hubbell; concentrate smelted by Calumet & Hecla smelter.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

WHITE PRECIPITATE often found in zinc-boxes is generally a mixture of zinc oxide and zinc ferrocyanide, and its formation has no connection with the use of lime in the treatment of the ore, for which it is often mistaken.

FERROCHROME is now made in an electric furnace at Trollhättan, Sweden, from ores brought from Africa and New Caledonia. It is estimated that the output in 1913 will be 1200 metric tons. While the process is as yet secret, it is said that 1700 kw. is required per ton of metal.

INDEX numbers are used to show the variation in prices as a whole. They are made upon various bases. For example, the *Annalist* index number reflects the average price of 25 food commodities selected and arranged to represent a theoretical family's food budget. The yearly averages have been: 1890, 109.2; 1896, 80.1; 1910, 137.1; 1911, 131.1; 1912, 143.2. The index number for the week ended November 1 was 141.6.

CHEMICAL differences between wrought iron and soft steel are slight. The iron contains little, if any, manganese, only such as may remain in the pig iron, whereas in steel manufacture manganese is added for purifying. The carbon content is slightly less in wrought iron. The main difference is structural, the wrought iron containing layers of slag which divide the iron and give it a fibrous structure at the same time that they retard oxidation.

COMPOSITE metal prices are used, as are index numbers, to reflect the general trend of prices. The theoretical pound of metal sold November 3, according to the *American Metal Market*, for 9.904. This is made up of 4 lb. of lead at St. Louis price; 2½ lb. of spelter, also at St. Louis price; 3 lb. of electrolytic copper at New York price; ½ lb. of tin, also at New York price; the whole divided by 10. Clearly the value of such a composite number is influenced by the proportions chosen as well as the quotations; if, however, the base be the same, sequence of change is brought out.

THE United States Bureau of Mines now has in the Matanuska coalfields of Alaska an expedition which has begun operations on the mining of 1000 tons of coal; this coal to be taken to tidewater and tested in Alaskan waters on the cruiser *Maryland*. One year ago the Bureau mined 800 tons of coal in the Behring River field for the same purpose. It is expected that these tests, which are being made in behalf of the Navy, will give a definite idea of the value of Alaskan coals and that their commercial development will follow soon after.

PROSPECTORS in Nevada may obtain useful information from the Mackay School of Mines, along many lines. For example, Circular No. 2, printed for their benefit, includes notes on the value and market for minerals, and the methods of sale of ores. There is a table of production with average unit prices; the 'Current Prices of Ores and Minerals' published regularly in the *Mining and Scientific Press*; the average price of minerals in carload lots in New York in 1910 as given in 'The Mineral Industry'; standard bases for purchase of lead and zinc ore; and names of buyers of ores and minerals.

IN smelting cyanide precipitate, the regulation of temperature has much to do with the efficiency of operations. If the temperature is allowed to rise too high during the fusion stage there is violent ebullition, and the capacity of the crucible is considerably reduced. The temperature variation required in an ordinary fire assay may be used as a guide, and as soon as the whole mass is in a state of quiet fusion the temperature should be regulated so that no undue ebullition occurs. Fresh fluxed precipitate can

then be added from time to time until the full load has been reached, and after the mass has quieted down the temperature can again be raised in order to insure a thoroughly fluid pour. Oil fuel offers the best facilities for temperature control.

KIESELGUHR is one name for fuller's earth, which usually is a diatomaceous earth, made up of the minute silicious skeletons of diatoms. It is also known as Tripolite, and by various trade names. Aside from its proper uses as a bleaching agent and as an absorbent for unstable materials, as when used in making dynamite, it is frequently employed as an adulterant and for 'loading' cloth and other materials. The compact varieties are cut into filters and it is also crushed for use as a polishing material and for making heat-protecting packing for pipes. Large quantities are used in the chemical industries such as the making of water glass, paper, pigments, safety matches, and *papier maché*. It occurs in many parts of the world, and deposits have recently been reported in Chile where they may be of importance in the local manufacture of dynamite.

COPPER is determined by wet assay, and from this result smelters usually deduct 1.3%. The copper remaining is usually paid for at the New York quotation for electrolytic copper less 3c. Thus, if a copper ore showed by analysis 10% copper, 1.3% would be deducted, leaving 8.7%. At a quotation of 14c., the price per pound would be 11c. The 174 lb. of copper would return \$19.14. From this the freight and treatment charges would be deducted. Certain penalties for insoluble residue and credits for iron are made similar to the above, or else a flat treatment charge is made. Deductions for sulphur, arsenic, and antimony are also often made. Gold and silver in a copper ore are paid for in copper ores, although in cases only 90% of the silver is paid for at the New York quotation. Special contracts are made with large and steady producers.

THE CHALCEDONY from the dike that Omer Maris is working a few miles east of Manhattan, Nevada, is proving to be a useful product. It is an exceedingly hard rock, which, when broken to size, is used as an abrasive in tube-mills, supplanting the beach pebbles which have heretofore been imported from Europe. The use of such rock in the southern Nevada mills amounts to about 200 tons per month, and it is expected that this demand may be supplied with the home product. The local mills now running are making use of it with satisfactory results. The Tonopah-Belmont Milling Co. will use one tube-mill to give a thorough trial of the rock's efficiency, keeping a record of the amount used per ton of ore milled. To all appearances, and as far as local tests have shown, the rock is similar to the imported kind and at least equal in wearing and grinding qualities. If longer tests sustain this impression, its use will no doubt become general in southern Nevada.

THE value of a mineral or an ore depends upon the difference between the amount realized from its sale and the sum total of the mining, transportation, marketing, and general costs. A mineral deposit, in order to have value, must not only show that the mineral can be profitably marketed, but that there is a sufficient quantity to cover the capital investment required for plant and development. A certain part of the apparent profit must be used in order to redeem the capital investment required to put a project into producing condition. Not only must the deposit insure the return of the capital, but it must also show a fair commercial profit in addition. Mineral deposits may be classed into three divisions—those which have a sufficient quantity of mineral, unit market value, and capital investment to insure a profitable enterprise; those which have sufficient quantity and value, but which lack sufficient capital to provide low enough working costs; and those which, while they may have sufficient quantity and the mineral may have value, under existing conditions cannot be profitably operated, and which do not justify the investment of sufficient capital to make the production costs low enough.

Book Reviews

THE MINING WORLD INDEX OF CURRENT LITERATURE, Vol. III. Edited by George E. Sisley. P. 158. Index. The Mining World Co., Chicago. For sale by the *Mining and Scientific Press*. Price \$2.

This volume, which is the third of the series, covers the world's literature on mining, metallurgy, and the allied industries for the first six months of 1913. It has been the aim of this work to include all articles of importance which have been published during this period pertaining to the technology of mines and minerals, and within this list will be found an invoice of a large majority of the world's leading publications. The large mass of material has been classified and systematically indexed in such a manner that the information on any branch of the subjects treated can be readily found. As a complete bibliography and technical index the work is most commendable, and to the engineer who desires to have at hand an index of the current literature it serves a useful purpose. All of the articles indexed can be had through the Mining World Company.

RADIUM: ITS PRODUCTION AND USES. By Sydney Fawns. P. 60. Ill., index. *The Mining Journal*, London, E.C., England. For sale by the *Mining and Scientific Press*. Price \$1.

It is estimated that there is only 30 to 35 gm. of pure radium bromide in use in the world, the annual consumption being from 10 to 15 gm., while the price keeps steady at about \$77,500 per gram. Ores containing radium in commercial quantities at present are only mined in Austria, Cornwall, Colorado, and South Australia, while production of the compounds is from works at Joachimstal, Austria; Giff, France; London, England; and Sydney, New South Wales. There is a good demand for uranium ores containing pitchblende, from which the radium is extracted by a complicated process known as fractionization. This interesting little volume contains everything connected with radium: its history, appearance, and energy; radio-activity of the earth; description of rays and emanations; the electroscope by which ores are 'assayed' for radium content; uses of radium; occurrences of radium-bearing ores; reduction and extraction of the metal; a bibliography of other works on the subject; and an appendix containing notes on calculating radium from uranium ores, and details of such ores. The book contains a frontispiece of Mme. Curie, who is so well known as an investigator on the subject, with the late Pierre Curie, Becquerel, Rutherford, Joly, and Soddy. The work covers the subject in a most interesting and instructive manner and will be enjoyed by those interested in this rare element.

METALLURGICAL ANALYSIS. By Nathaniel Wright Lord and Dana J. Demorest. P. 334. Ill., 3rd ed. McGraw-Hill Book Co., New York, 1913. For sale by the *Mining and Scientific Press*. Price \$2.50.

This is an excellent revision of an excellent book, and combines comprehensiveness with conciseness. Twenty years ago Nathaniel Lord, then professor of metallurgy and mineralogy in Ohio State University, published in book form the laboratory notes intended for his students in analytical chemistry as applied to metallurgy. In the present edition Mr. Demorest, who has succeeded to the chair of metallurgy, has rewritten the work throughout so that the latest practice may be included. New chapters have been added and the worker in the chemical laboratory of a metallurgical plant will be able to find practically everything required in ordinary practice within the covers of this small book. The title page alone throws an interesting side light on American metallurgy in the past quarter century. Nathaniel Lord was one of a half dozen men who taught both metallurgy and mineralogy in the early days of mining education in America, a curious conjunction, the influence of which has not yet entirely disappeared. He, however, combined with these the teaching of analytical chemistry, which is, after all, but a single subject, whether the analysis be of alloys for the manufacturer, ores for the smelter, rocks for the geologist, or soils for the agricul-

turist. The relation of analytical chemistry to metallurgy may be regarded as close, or as somewhat remote. As a matter of fact, analytical chemistry is as subservient to metallurgy as brick-making is to architecture, or as physiological chemistry is to medicine, and the coming relation of the two is now foreshadowed at Toronto University, where the students in metallurgy are relieved of analytical work, just as would be the case in the management of a plant. A man can know too much detail, and the chief clerk rarely makes an efficient general manager. The moral of this is that books such as this are more for the chemist who expects to work upon the materials of metallurgical practice than for the metallurgist *per se*.

ORE DEPOSITS. By S. F. Emmons. P. 954. Ill., index. Published by Amer. Inst. Min. Eng., New York, 1913. For sale by the *Mining and Scientific Press*. Price \$5.

This so-called 'Emmons Memorial Volume' on ore deposits is less a memorial to him than a forceful example of how impossible it is to write comprehensively of ore deposits without bringing out the great part he played in the development of modern ideas on this subject, and recurring constantly to our heritage from him of ideas and ideals, which is Emmons' best memorial. A man who leaves so firm an impress on a whole science as Emmons did, needs no other memorial; though it may still be pleasant and profitable to erect one or more to him.

The book in question is a compilation of certain significant papers on ore genesis published in the *Transactions* of the Institute and selected for republication by Emmons before his death. It is preceded by an introduction that he prepared and which adds greatly to the value of the volume, as also by a charming sketch of his career written by his life-long friend, G. F. Becker. We wish all the young men of the profession could read both of these, as they depict not only what has been done in the last forty years in the study of ore genesis, but the admirable spirit in which the work has been prosecuted. As to the papers themselves that have been included in the volume, we can only say that the choice has been most happy. As a whole they are the significant papers of the period, due allowance being made for those already reprinted in the earlier or 'Posepny' volume. The student who masters them will have a comprehensive and fairly accurate conception of modern beliefs as to the genesis of ores, and will have obtained it by that best of methods, comparison; the study of diverse interpretations by different engineers. As Emmons quotes King, the true theory of genesis of deposits is only to be developed after "the varied types of deposits in all the important mining districts * * * have been studied." This work is still incomplete, but at least it is now possible to recognize with fair assurance some of the final types, and to this Emmons contributed mightily.

The formal papers here reprinted number 29 and range from 'The Genesis of Certain Ore Deposits' by S. F. Emmons in 1886, to 'The Agency of Manganese in the Superficial Alteration or Secondary Enrichment of the Gold Deposits in the United States' by W. H. Emmons in 1910. The first is general, designed to correct misapprehensions of certain critics of the classic Leadville report, and the last is a specific application of the newly formulated doctrine of secondary enrichment to a certain group of deposits. In a way, this progress from the general to the detailed is characteristic of the development of knowledge in the period indicated.

It would require too much space to review in sequence the numerous individual papers or even to list their authors. The studies here reprinted are already widely recognized as permanent contributions to the body of knowledge. They are now given convenient form and rendered readily accessible to many who do not have the whole file of *Transactions* at hand. They are admirably supplemented by the classified bibliography and digest of cognate literature and summary of papers in the *Transactions* but not included in this volume, prepared by J. D. Irving. The volume as a whole is one that each engineer will want in his own library and that students may well thumb.

H. F. B.

Sullivan Angle-Compound Air-Compressors

By FAED 'D. HOLDSWORTH

The Sullivan Machinery Co. is now manufacturing what is believed to be the first angle-compound air-compressor offered in commercial sizes. A number have been installed at mines in Arizona, Utah, and elsewhere and are giving excellent satisfaction. Angle-compound engines have been used for many years under conditions demanding high speed, freedom from vibration and close economy, and some special air-compressors of very large capacity have been built on the same principle. The Sullivan 'angle-compound' may fairly claim, however, to be the only power-driven compressor of this design now being manufactured in ordinary commercial sizes.

The angle-compound air-compressor has its low pressure or intake cylinder in a horizontal plane, with the high pressure cylinder set vertically, on the end of the horizontal frame. Both pistons are actuated by a single crank, and both sets of valve gear by a single eccentric pin. The driving pulley or motor is mounted at one side, on an extension of the crank shaft. This design permits a very close balancing of reciprocating masses. The momentum of moving parts increases as the square of the rotative speed, and the matter of balancing is of larger economic importance for engines and compressors which are intended to run at comparatively high speed than has generally been recognized. The perfect balance of the angle-compound compressor saves for useful work power otherwise wasted in friction and vibration. The output per unit of floor space has also been increased, and this with an actual advance in accessibility of all parts. This saving of floor space is accompanied by a reduction of strains on the foundation, and this is of correspondingly small dimensions. No lining up, except leveling, need be done; no expensive or intricate problems in driving attachment need be solved, and the installation cost, often a serious item in other compressor types, is always a small matter in this machine.

FIG. 1.

The reciprocating parts of a high speed steam-engine or compressor offer problems in balancing that are extremely difficult of satisfactory solution. Opposing balancing weights attached to the crank produce uniform opposing centrifugal forces radially around the shaft; while the inertia forces set up by the motion of the reciprocating parts change constantly in intensity throughout a revolution, in line with their motion. They are started from a point of rest at one end of the stroke, accelerated to maximum speed about mid-stroke, retarded from this point, and brought to rest at the end of the stroke. In accelerating the reciprocating parts, force has to be applied to them from the crank, tending to oppose its rotation, and they become charged, so to speak, with potential energy due to their velocity. After their maximum velocity has been reached at mid-stroke, and retardation begins to take place, the energy absorbed during the first half of the stroke is given up during the latter half, producing a force tending to assist the crank in its rotation.

In compressors of slow or moderate rotative speed, say 150 r.p.m., the disturbing effects of these inertia forces are so small that they are readily absorbed by the mass of the entire machine, but as the inertia varies as the square of the speed, it will be seen that if it is attempted to run such a compressor at a speed of 225 r.p.m. the disturbing

effects have been increased in the ratio of $(\frac{225}{150})^2 = 2.25$. In other words, with a speed increase of 50%, the disturbing forces produced by the reciprocating parts have increased 225 per cent.

The inertia of the reciprocating parts reaches a maximum at the ends of the stroke, and is equal in value to the centrifugal force of a mass having the same weight as the combined weight of the piston, piston rod, cross-head, and connecting rod. Fig. 1. shows the effect of these forces, plotted radially about a neutral circle; and they are shown to be maximum at either end of the stroke. The difference in shape of the curve on either side is caused by the angularity of the connecting rod. As stated above, the effect at the ends of the stroke is equivalent to the centrifugal force of a revolving mass of the same weight as the reciprocating parts, and the horizontal vibrations may be entirely neutralized by attaching such an equivalent weight to the crank opposite the crank pin. If this be done, however, the result will be as indicated in Fig. 2. Here the opposing cen-

FIG. 2.

trifugal force of the revolving weight has practically neutralized the inertia forces, but has introduced a new set of vertical unbalanced forces, of equal intensity, tending to shake the shaft and engine up and down.

In horizontal single or duplex compressors, it will be seen that good balancing is an impossibility, and the best that can be accomplished is a compromise, effected by attaching a centrifugal counterweight, of less weight than that of the reciprocating parts, which will partly absorb their horizontal disturbing effects without introducing vertical unbalanced forces of injurious magnitude, leaving the bearings, frames, and foundations to absorb the remainder.

In the angle-compound compressor, the disturbing influences of the horizontal and the vertical members tend to offset or neutralize each other, the maximum unbalanced

FIG. 3.

effects of the vertical parts being produced when those of the horizontal parts are at minimum value and vice versa. This result is illustrated in Fig. 3. Here two curves, dupli-

cates of Fig. 1, are shown at right angles to each other, curve A representing forces in the horizontal, and curve B those of the vertical machine. Curve C represents the sum of the two curves, and approximates, roughly, a circle, showing that the disturbance produced is more nearly uniform throughout the revolution. In Fig. 1 it will be noted that the disturbing forces fluctuate between 0 and 2300 to 3200 lb., while in the combined curve in Fig. 3 there is a difference, between a maximum of 3300 and a minimum of 2200 lb., of 1100 lb. only.

An opposing revolving weight, producing a centrifugal force, practically equivalent to the inertia forces of the reciprocating parts at the ends of the stroke, will produce the effect shown in curve D; indicating that the unbalanced forces have been reduced from approximately 3000 lb. in Fig. 1 and 2 to 500 to 700 lb. in Fig. 3.

The beneficial effects of such a marked reduction in forces tending to set up vibrations are manifold. One of the main obstacles to high rotative speed having been removed in this design, a smaller machine may be used for a given duty, provided it is designed with proper valves and valve areas for its rated speed, thereby involving savings in the original investment, space requirements and foundations.

The massive foundations necessary to absorb the unbalanced vibrations in other types are not required for the perfectly balanced angle-compound compressor, and it may be successfully operated in buildings where vibration is objectionable, or on unstable or filled ground, where vibration would have a tendency to cause unequal settlement and throw the compressor out of alignment.

The heavy counterweight permitted by this design practically absorbs within the shaft itself all of the heavy inertia loads which would otherwise have to be carried by the crank shaft bearings, and leaves these important elements of the compressor free to perform their proper function of carrying the load due to the air pressure on the pistons and to support the weight of the moving parts, thereby greatly reducing power losses due to friction, trouble with heated bearings, and similar annoyances.

In addition to the elimination of inertia loads from the bearings a further benefit is gained by a more uniform distribution of the working pressures around the circumference of the crank shaft boxes. In the horizontal type of machine, the wear due to the influence of piston load is all on the sides of the boxes, while with the angle-compound type the piston load produces wear in both horizontal and vertical directions, with the result that the boxes require less adjustment, the wear is distributed over a greater surface, and both the shaft and boxes retain a more nearly cylindrical shape throughout their life, resulting in unusual freedom from pounding.

In the ordinary duplex design, the stresses due to piston load are applied to the ends of a crank shaft supported in bearings several feet apart, and as the piston loads during certain parts of the revolution act in opposite directions, a twisting effect or couple is set up in a horizontal plane which must be resisted by the machine frame, the foundations or both. Any lack of rigidity in these elements disturbs the alignment and produces a tendency toward heated bearings and increased friction. In foundations for duplex compressors, which are necessarily of large horizontal dimensions, if any settlement occurs, it is bound to be unequal; and the wide base or frame cannot be made stiff enough to resist the distorting forces of the settling foundation. The angle-compound compressor foundation is short and narrow, and if settlement occurs, the foundation, in tilting from a level position, will move as a solid block or unit, and no distortion of the frame will result. Furthermore, this frame is of great depth in comparison to its width, giving it a rigidity far in excess of that found in the broad and more flexible base supporting the duplex compressor.

The unique arrangement of the cylinders in the angle-compound compressor permits the placing of both connecting rods side by side on the same crank pin. This feature reduces the distance between the centre lines of the two cylinders from several feet, in the duplex, to the width of one connecting rod box in the angle-compound type, and practically eliminates the severe distorting forces, which

have been referred to in the preceding paragraphs.

The crank shaft is supported in large bearings immediately on either side of the crank pin, so that the load imposed by both pistons is borne equally by these bearings, without any tendency to rock or spring the shaft or main frame.

A New Stretcher

The Kny-Scheerer Co. is manufacturing a special form of stretcher known as the Stokes, and designed to make it easy to carry injured men in awkward situations, as on shipboard and in mines. It was developed by C. F. Stokes, surgeon general of the United States Navy, and is used by the Navy, the Oliver Iron Mining Co., Inspiration Con. Copper Co., Copper Queen, Arizona Copper Co., Ltd., and other large concerns. The stretcher is so made that the injured man may be strapped in it and broken arms or legs held as in a splint. He can then be carried without further injury.

Commercial Paragraphs

The SULLIVAN MACHINERY Co., announces the resignation of Myron G. Doll, for several years local manager at Salt Lake City. H. E. Moon, heretofore associated with the Denver, Colorado, office of this Company, has been appointed local manager, as successor to Mr. Doll.

The UNION IRON WORKS Co., of San Francisco, has lately completed a large and expensive power-plant which includes electrically operated air-compressors, motor-generator sets, electric booster system, switchboard, distributing panels, and all accessory equipment. The Company is now offering for sale all the machinery in the old power-plant consisting of boilers, engines, compressors, pumps, electric generating sets, fans, blowers, and the complete piping system.

JOHN A. ROEBLING'S SONS Co. recently made tests at its Trenton, New Jersey, works of the wire ropes to be used as towing lines at the great locks at Gatun and Miraflores. Forty wire ropes each 400 ft. long have so far been made by the Roeblings for this purpose. Each rope has six strands, with 37 wires in each strand, the strands being twisted around a hemp centre. The ropes are 1 in. diameter and have a 4-ft. loop at one end. The specifications for ropes called for a tensile strength of 37 tons each. To obtain this requires a tensile strength in the wire of 260,000 lb. per square inch. Pieces cut from ends of the ropes, when broken in the testing machine, showed the ropes to have strengths ranging from 12 to 15% in excess of that called for by the specifications. In towing boats through the locks four electric locomotives will be used for each vessel at each lock. Two of these locomotives will be connected by wire ropes to the bow and two to the stern.

The BALDWIN LOCOMOTIVE WORKS signalized the completion of their forty-thousandth locomotive recently by publishing a most attractive booklet in which something of the history of the Baldwin works is told. This is at the same time the history of the art in America since the Baldwin works have been building locomotives for 82 years. Indeed, the Standard Steel Works Co., a subsidiary, goes back to the famous Freedom Forge, founded in 1795. It comes as a bit of a shock to realize how far back in the past some of the manufacturing concerns in this young country, may be traced. The Baldwin concern began modestly enough in 1832. Things moved slowly then, and it was 30 years later that locomotive 1000 was completed. The five thousandth was turned out in 1880, the ten-thousandth in 1889, the twenty-thousandth in 1902, and the thirty-thousandth in 1907. It is evident from this record that the benefits of good work were accumulative, and it is pleasant to know that demand has so continued to increase that the original Philadelphia works were long since outgrown. At the Eddystone, Pennsylvania, the East Chicago, Indiana, plants, and the Standard Steel Works at Burnham, Pennsylvania, the Company has now works of which it may well be proud, while around the world its locomotives are disproving the old superstition that only European plants built honestly and to last.

EDITORIAL

DECLINATION by Mrs. Pankhurst of a proposal of marriage by the holder of the United States record for fasting, removes the hope of an interesting international attempt to defeat the high cost of living by eugenies.

A REPORT from Nome states that many of the old time placer miners are of the opinion that the storm of a month ago washed enough gold on the beach to more than pay for the damage done by the elements. If such proves to be the case, storms may be looked upon as a blessing rather than a bane in the future.

THE session of Colorado editors at which both sides of the strike of the Colorado coal miners was presented, resulted in adopting a resolution that the strike should be declared off immediately and that the union should give up its demand for recognition by the operators as well as abandon claims for higher wages. We believe that the expression of this meeting voices the sentiment of the people of Colorado, and if so, success on the part of the strikers can hardly be anticipated.

THE attack on the President and the administration's Mexican policy by Mr. D. P. Barrows, acting president of the University of California, reads more like the outburst of a petty Mexican ranch owner who would precipitate intervention because of the theft of a steer by the revolutionists, than that of an authority on international affairs. It is a surprising variant from Mr. Barrow's usual excellent discussions of contemporary history. When a university president preaches jingoism, one is led to believe that there is some truth in the statement that the sphere of the average professor is a rut, which has been likened unto a coffin that is open at both ends.

MINE taxation was one of the problems touched upon by Mr. D. W. Brunton in the well balanced presidential address that he delivered before the American Mining Congress at Philadelphia and which we print this week. Interest in the problem is widespread and is especially keen in Colorado, where, as Mr. Brunton pointed out, a most anomalous system has been evolved. The local members of the American Institute of Mining Engineers, as related in our Denver letter, made the matter the subject of discussion at a recent meeting and have appointed a strong committee to study the situation further. Incidentally, we note that the meeting was preceded by a dinner, an excellent means of establishing a friendly basis for debate. We present in

our news pages an account of the meeting and a picture of the men at dinner.

NEWSPAPER accounts of mines and mining are frequently trivial when they are not inaccurate, and the so-called financial journals usually refuse to consider mining seriously. An honorable exception is the New York Times *Annalist*, the weekly issue devoted to finance, commerce, and economics. This well written and well informed journal maintains a regular department devoted to mining. As its editor is Mr. C. S. Burton, long the New York correspondent of the *Mining and Scientific Press*, the information printed is timely, interesting, and unusually accurate. We congratulate the *Annalist* on recognizing mining as one of the fundamental industries of the country, without discussion of which no complete forecast of industry is possible.

SAN FRANCISCO engineers celebrated the opening of the new quarters of the Engineers' Club in Hotel Sutter last Saturday night by an entertainment in the course of which men from each branch of engineering gave practical exemplification of their skill. The miners made a good impression with a drilling contest, in which Messrs. Edmund Juessen, J. M. Parks, Clifford Dennis, and C. E. Grunsky, Jr., were contestants and over which Mr. E. H. Benjamin presided as referee. Mr. W. A. Williams drilled in a successful oil well despite the unfavorable opinion of such experts as Messrs. W. R. Hamilton, E. B. Kimball, and D. M. Folsom. The new club is proving a useful centre for extending acquaintance among men of the engineering professions and is bringing to light unsuspected talent in other directions.

INTERESTING reflections regarding copper exports are suggested by the graph below. The figures show conclusively that recent exports are abnormally large, but they also show that large fluctuations are normal. The inference from the October figures is that they have begun to decrease again. The line has been projected to January 1, 1914. If the exports for the last half year amount to double those for July to October, it would run to the point A. If, however, the October shipments be taken as the true guide for the last quarter, the point B would be the correct one, that point having been found by multiplying the October shipments by six.

MACHINERY is not the only element in successful mill work, and a manager must be prepared to spend time and thought on his men as well as his machines. It is an old saying that 'there is a lot of human nature about folks,' and one that it is well always to keep in mind. Mr. Gelasio Caetani, in an address before the students at Harvard, which we print this week, points out some of the many ways in which the human factor must be taken into account if one would become a successful millman.

Doubtful Leadership of Labor

In a recent speech at Seattle, Mr. W. B. Wilson, Secretary of Labor, is credited with having made statements that will go far to destroy the feeling of confidence in him and the new department that was gaining ground. Mr. Wilson is a long time trade unionist and was at one time secretary of the United Mine Workers of America. As one of the men who supported Mr. John Mitchell in building up that organization, he came prominently before the public. He and his associates proved the place and value of collective bargaining in modern industry, never more so than when by carrying through a reduction in wages, they showed that the scheme really could be made to work both ways. In view of the chaotic condition of our anti-trust laws, the bituminous industry has been for years fiercely and disastrously competitive, and it is an open secret that the United Mine Workers has been the most important agency for leveling conditions and enforcing a measure of equality in this competition. Labor union officials are expected to be radical, but among them, Mr. Wilson has been a conservative and he has also been constructive. His career as a congressman, while not distinguished, has been clean and creditable, and his appointment to the Cabinet was considered appropriate and fitting.

It is a disappointment to find such a man forced by the exigencies of position to defend so discredited an organization as the Western Federation of Miners. Its history is an open secret through the West, and, despite loud protestations of reform, the fact remains that Mr. Charles H. Moyer is still president; and this is the Moyer of Leadville, Cripple Creek, Telluride, Goldfield, and Idaho fame. No one doubts but that the mine managers of the Lake Superior country would willingly make any reasonable concessions to their men, but no experienced Western mine manager can do otherwise than sympathize with them in their refusal to treat with the Western Federation of Miners. We are among those who believe in labor unions and in collective bargaining, but we do not believe that workingmen have anything to gain by fighting the battles of such men as Mr. Moyer.

It was doubtless a severe disappointment to the officers of the new Department of Labor that official mediation in the strike was refused. As sincere believers in trades unionism, they naturally feel that the operators should recognize the particular union that makes a show of strength in the district. It is also true that the alternative of destroying the Western Federation may be the upbuilding of the mis-named 'Industrial Workers of the World.' We

would hope, however, that another alternative would be the coming forward of a conservatively managed union; one knowing more about mining costs and less about dynamite. In the meantime, Mr. Wilson will do well to look less to the immediate cause of irritation and more to fundamental causes. World-wide conditions cannot be changed in a day, and political 'bunk' is no sufficient substitute for sound knowledge.

Education That Educates

The question, 'What constitutes an education?' brings answers as varied as there are viewpoints. In the Middle Ages, familiarity with Latin and Greek was enough to put the then limited store of knowledge at the service of anyone with the time and inclination to do a little reading. Today no ordinary lifetime would suffice for a man to familiarize himself with the important treatises published in English in the past hundred years alone. A metallurgist, for example, finds it increasingly difficult to even keep moderately well informed of progress in that knowledge of inorganic chemistry on which his art is based. So we have come to a present-day standard of practical education in which an accurate comprehension of the basic principles which underlie all knowledge, and a complete mastery of the details of some one branch, is regarded as the working ideal. It is unfortunately true that a large part, perhaps a majority, in our population possess neither of these, since faulty methods of primary education have not condued to the former, and a natural desire to keep abreast of the times tends to substitute for the latter a smattering of many things. Extending the doctrine of Malthus from the material to the intellectual world, it may be said that there is impending an equilibrium between the world's fund of knowledge and the capacity of the human brain to make any useful application of it. As a result, everyone is content to remain in contact with many things he does not understand. Thus, to choose a familiar example, automatic weighing devices attached to conveyor belts form a common feature of industrial plants, yet it is rare to find anyone on the staff of the plant who has a competent knowledge of how they are constructed, or how they do their work. Everybody uses the telephone, but few understand it, beyond that an electric current, magnets, and vibrating diaphragms give the desired result. Absurd as the statement may at first seem, it is certainly open to question whether the general public has a clearer detailed understanding of the world in which it moves than was the case in the Middle Ages. The great advance in general understanding has perhaps been more than compensated by the tremendous increase of complex objects of knowledge. The pursuit of knowledge thus appears a hopeless race for the generality of mankind, and the present condition of affairs, in which a comparative few seek the ultimate boundaries of research, while the many make the best use possible of what others furnish, seems likely to become a permanent relationship.

Looking at the matter from this viewpoint, it is clear that educational methods are and have been

fundamentally wrong, being founded on erroneous conceptions of the mental psychology of the child and perpetuated in schemes which are not adapted to secure the end desired. What is requisite is to give each child primary training which will lead up to either a mastery of the knowledge of others, or the ability to advance the bounds of knowledge; trusting to the child, when he reaches the proper age, to automatically determine which of these two paths to follow. On the range it is the custom to let a colt run wild until it is old enough and strong enough to work under the saddle. It is then roped, 'broken', and put to work. Something similar has been the practice in our schools, where the exact manipulations of laboratory work in physics and chemistry are suddenly introduced with the high school course at an age at which the child has had ample opportunity for his natural aptitude for such work to atrophy and disappear. Thanks to Madame Maria Montessori, the most obvious fact that the highest serviceability of the human senses can only be secured by beginning their training at the earliest possible moment has now gained universal acceptance, and it is not too much to hope that educational methods, from the primary school to the university, will soon be recast along more rational lines.

Out of this faulty conception of education arises never-ending controversy over the relation between general education and vocational training. In a recent report Mr. Nicholas Murray Butler, president of Columbia University, said that vocational training, carried to its logical result, would mean a stratified and static social order which would put an end to individual initiative and to individual opportunity. On the other hand, Mr. T. W. Robinson, first vice-president of the Illinois Steel Company, has recently made an eloquent plea for vocational training, which he declares is not a passing social expedient, but a method which results in greater industrial efficiency and increased economic truth, morality, and civic duty. The two men are regarding the obverse and reverse of the same shield. The child is now thrust into vocational training without the fundamental requisites of general training because we have been too inept to convey them to him in his early years, relying upon the horse-breaking method of conveying them by painful application of the 'three R's.' The possession of an education is indicated by mental horse-power, not by ability to quote Greek or Sanscrit. Given a proper training in fundamentals, the average student will obtain more real education from vocational training than from the study of abstract knowledge. The competent mechanic knows how to use tools, where they are kept in his shop, and how to make new ones if necessary. Similarly, the educated man knows how to think accurately and logically, and what records of the study of others are available, while competent to study individual problems as the need arises. The Mining and Metallurgical Society has a committee at work studying the practical training of engineers. We believe that it will be found that more failures are due to lack of grounding in principles than similar lack of familiarity with practice.

The Human Side of Milling

By GELASIO CAETANI

Not many years ago, when I graduated, one question that vividly interested me was to know what the experience of others had been during the first years after leaving college. What impressed me very much was to see the great influence that unimportant circumstances may have on our future and how a small incident may at times change entirely the direction of our career.

I began by graduating as a civil engineer and architect in Italy and find myself now specializing in ore dressing. I understand that F. L. Bosqui, the well known metallurgical engineer, graduated as a physician, all of which goes to prove that one may train himself for one profession and then actually follow a very different one; the course of our studies does not absolutely determine the course of our lives.

College Education

Some people, especially those that have not had the opportunity of going through college, believe that the main object of a college education is to memorize a long and obtruse series of facts that one would never have taken care to study unless somebody had obliged us to do so. As a matter of fact, we memorize a great deal during school years and remember very little; all we really do is to make an inventory of human knowledge, so that we may know what there is of human knowledge, where to find it, and how to use it in the moment of need. The real studying begins after leaving college, and it is right to say that the school is more for the purpose of learning how to study than for that of studying what there is to be learned.

The most valuable asset that is gained at college is the scientific training; it is the art of looking at things in a clear-minded way and of using common sense in the solution of both technical and moral questions. A man with a good technical training is well equipped for whatsoever technical profession; the man who in life has been a successful mine manager would have been equally successful had circumstances in life made of him the manager of a cotton spinning mill or of a paper factory.

The knowledge of technical facts peculiar to any one industry is quickly acquired by any man equipped with a good technical training, and it is for this reason that, in my opinion, a course of civil engineering will equip a man for the mining profession just as well as a course in a school of mines. I have taken a degree in both courses and have always had the impression that my civil engineering studies have been of greater support to me than my studies in mining. The reason of it probably is that mining in general is one of the broadest applications of civil engineering; the problems that arise in the mining industry do not generally call for calculus and higher graphical statics, but at the same time a mining engineer will be called to make use of more branches of modern technology than is the case in any other industrial enterprise.

With all this, technical training counts little when compared with will and character, as it is upon this that any success in life depends. Every year the mining schools of the country turn out from two to three hundred mining engineers fresh from the mint. These engineers all get a start at the same moment and are more or less all on the same footing, inasmuch as regards technical training. Of these two or three hundred men, a number drop off along the road, the greater number will settle here and there in minor positions and only a few will reach the top. What differentiates them one from each other is not the technical training, but the will, the mind, and the character. These qualities establish our relations with our fellow-beings, and it is just on this account that they are of paramount importance. There is nothing one could do if left completely alone; every move, every action, any success that may be achieved in life is necessarily and primarily connected and dependent upon our fellow-beings. All our future is dependent on the coöperation of other people with ourselves, and it is therefore true that the knowledge of human nature, the acquaintance of other men, and the art of dealing with other men, will be the determining factor of our success or failure in life. This art is not learned at school, but is acquired slowly by experience, while shifting from one camp to another, and the more one wanders the more one sees of things and of human nature.

When I graduated, I made up my mind that I would not attempt to make any headway during the first few years; I had decided that I would try to get as wide and as varied experience as I could and that I would not hold on to any one job for over six months, even if by clinging to it there was a good chance of advancement. I never made a secret of this, and therefore never aimed for a position that would be given only to a man who intended to stick to the job for an indefinite period of time.

Early Experience

So I wandered over the country, gaining varied and interesting experience both of things and of human nature, and never felt any compunction in letting go a \$5 job to take up a \$2.25 job when the limit of time I had prefixed for myself had run out. These were my 'Lehrlingsjahre,' and in the three or four years that they lasted I learned more than I ever learned at school, because I learned, without realizing that I was studying, and remembered things without attempting to memorize them.

The advice I would give is to do the same thing, though others may point out to you that the best policy is to get in with some company where the possibilities for the future are good and to stick there like glue. This system may be a good one to follow when the principal aim in life is to settle as soon as possible into comfortable quarters; my personal opinion is that a young man should not attempt to realize too soon on his own capitalization, but, as you would say, keep on investing all operating

profits in development work and capital improvements.

This roving spirit in a college graduate is a hindrance in obtaining positions that involve responsibility of some kind. You cannot blame a mill foreman if he objects to hire as jig-man a graduate who, after wasting a lot of good mineral in studying the idiosyncrasies of a Harz jig, will suddenly quit the job to join the office staff or to leave for some distant camp. It is an old saying in the Coeur d'Alene district that every new jig man will waste more in a month than he is paid in a year. On this account those that have in them the 'Wanderlust' must give up the idea of making headway during the first years of practical experience.

Prejudice Against College Graduates

The old time prejudice of the 'old hands' that college graduates, or 'college guys,' as they are called, are no good, generally in the way, and always ridiculous, is gradually wearing out. In most reduction plants college graduates are holding the more responsible positions, and the great majority of college men that I have known working as mill hands were to be credited with good and intelligent work. The most damaging characteristic of the green graduate is his consciousness of science. The desire for manifesting to others the stores of knowledge acquired, is in reality only an attempt to convince one's self of one's own merit, because to the other party such vain-glorious display generally causes a feeling of irritation and diffidence. The man of real knowledge does not feel the need of impressing this fact on others. He will realize, instead, how much there is still to be learned and will listen with attention to whoever may have something interesting to say. I mention this because a common defect of many green graduates (and I have been one of them, too) is that when asking for information they are afraid to expose their own ignorance; they try to shield themselves by assuming the airs of a man well acquainted with the subject and acknowledge what they are told with understanding grunts, instead of frankly acknowledging their ignorance and showing their willingness to learn. My experience has been that such frankness, coupled with a sincere desire to learn, is the most reliable introduction a man can have at any plant, and when you enter a mill in brand-new overalls this policy will quickly acquire you a mentor and probably a friend.

As a rule, millmen are of kinder and gentler disposition than underground miners, and I have never found any difficulty in becoming good friends with the 'boys.' The blacksmith generally, and the carpenter every now and then, are the cranky elements of mill crews; this is a kind of tradition.

As a whole, a mill crew is more clannish than the other labor elements in a plant. It is also a more conservative element, and labor agitators do not find as much response in the mill as they do in the mine.

The most usual way for a college graduate to enter a mill is either as laborer or on some experimental work. In the first case he will seldom find any difficulty in getting along with the millmen as long as he minds his own business and does his full

share of work. The second case is entirely different, and the green college graduate who is appointed to carry on an extensive series of mill tests will often get into trouble if he does not use judgment and tact. Experimental work generally interferes more or less with the routine mill work; it is generally given precedence over the operation of any individual machine in the mill, though it must never be allowed to interfere with the general operation of the plant.

When experiments are being carried on it is necessary to install temporary launders that generally leak; some machines are robbed of their feed, the floor space is taken up with sampling boxes and iron buckets, and, more often than not, the water-hoses in the neighborhood of the testing plant are monopolized by the 'experts.' With all this, the millmen will generally be found to give a helping hand and often some good advice; in return, the man who runs the tests must strive to take upon himself all the burden of the extra work caused by the experimenting. There is probably nothing that irritates a millman more than to find an outsider making a big mess around some part of the mill and then walking off without putting back everything as he found it. Go to a millman and ask him for a wrench and he will give it to you most graciously; forget to bring the wrench back so that he must hustle it back for himself and he will cuss you to perdition. A carpenter may not mind very much if you attempt to ripsaw a twenty-penny nail with his crosscut saw, but he will cuss at you if he finds it rusted next day because you forgot to wipe and oil it. It is the old Christian maxim of treating others as you wish to be treated yourself, and as long as you follow this rule you will fare well.

Eventually, as you advance in your work, you will be given charge of a plant. When this takes place, a man feels an irresistible desire to enforce immediately all the reforms that have been brewing in his mind for some time past and to make all those changes in the mill and to the flowsheet that he has so diligently studied before having authority to carry them out.

Reforms and Changes

It is a fundamental mistake for a man who is taking charge of a plant to begin by enforcing reforms and changes. Humanity is instinctively adverse to anything new, whether it be a new superintendent or a new jig, and you cannot make a success out of anything, especially in a mill, if you have not with you the sympathy and the good will of your men. I am willing to assert that any common-sensed machine can be made to work satisfactorily if there is some friend to look after it, and the most perfect of our standard machines can be made a complete wreck if entrusted entirely to unfriendly hands. As an example, you can take the Frue vanner, the most standardized of all concentrating tables; this machine is so full of mean little tricks and weaknesses that if it was invented and placed on the market today, it would be thrown out in every plant where the spirit was not sufficiently friendly to take care of its weaknesses for the sake of its efficiency.

So it will be with any reform or any new process

that the new superintendent may try to introduce. To operate a plant successfully you must have with you the good will and the friendliness of your men.

When the new superintendent is put in charge, there is for a time a general tension of feelings. The men are asking themselves "What's next?" Those with a poor conscience look for some wholesale 'firing'; the friends of the former boss seldom sympathize with the new one, and if the former boss was 'fired,' you can be sure that a certain number of his followers will quit. When this is the case, it is good counsel not to make any special move, but to let things hum along in the customary old way while getting a firm grip on the whole situation. Especially, if new in the place, it is unwise to modify any existing order of things without having thoroughly investigated the "why" of such ways. If something is done in a certain way at one plant, it is most probable that there is some very good reason for doing it so. Jigging of unsized material may be theoretically wrong and have been proved to be wrong in one camp, whereas in another camp it may be entirely justified and probably preferable. Once, however, that the new superintendent has taken a solid hold of the situation and its problems, he must not hesitate in carrying into effect whatever policy he thinks is right.

Essentials of Success

To gain and hold the esteem of the men who are under you, you must convince them of two things: first, that you know the business at least as well as they do, and second, that you are going to give them a square deal. The thorough practical knowledge of the work is chiefly expected from the foremen and bosses who are directly in charge of the workmen. The men higher up, that is, the manager or the president of the company, have seldom a thorough practical knowledge of every department of the plant, and this is not expected of them. These men have generally risen to their positions from some of the departments and hold their position more for their business ability and for their knowledge in dealing with men than for their thorough knowledge of the technical details of every department. What is expected of them is to impart the right spirit to every department of the plant and to pick out for heads of these departments men that will carry out the work in the right spirit and with technical ability.

It is to these men that the manager will impart his orders, and they in turn will pass the orders to the bosses, who will see that the orders are carried out. It is a fundamental mistake not to respect the organization of a plant as, not only will orders given over the head of the bosses cause confusion and conflicts, but this will also arouse the ill-feeling of the men in charge, because high-handed methods minimize their authority in the eyes of their men.

Authority is a dear thing to men of all ranks; a precious privilege to be jealously guarded, not so much for the material advantages it confers, as for the feeling of class distinction that, at least in the opinion of the man enjoying it, is constantly associated with authority itself. But whatever be the humorous aspect of the human side of all this, a

well defined authority is absolutely essential in an organization of whatsoever kind, and therefore must always be respected, even if it be only that of a 'straw-boss.'

The orders given to any subaltern must be clear and decisive, even if they are wrong. The men want clear orders, for a definite object and from a definite source; what the effect of the order will be generally concerns them but little. When an order is clear and decisive it is an indication that the boss knows his own business, and this is his most powerful asset in commanding the respect and good-will of his men.

From this it naturally follows that revoking an order is confusing and demoralizing. It is well to think out a question thoroughly before giving orders. If later you find that a serious mistake was made, revoke your order openly and decisively, but if the order has already been carried out in part and if no serious consequence has resulted, it generally pays to let things stand. It always irritates a man, and disgusts him, to be told to tear down something that he has just been erecting with painstaking diligence.

More difficult than to enforce new orders is the breaking up of pleasant and inveterate habits. Once a habit has been sanctioned by not being repressed, it ends by being considered as an inalienable right, and the abrogation of the privilege appears to the men an unjustified violation of their prerogatives. A characteristic instance comes to my mind. In one camp, the mills used to be operated on a twelve-hour shift basis. It had become customary that, as the shift drew to its end, the millmen would start washing themselves and changing clothes so as to be ready to leave as soon as the other shift appeared. This shift would then quietly proceed to change clothes and, in due course of time, place hands to the work. All this meant that, at the end of every shift, there was a period of about 35 minutes during which the concentrating machines were left to strive for themselves; when the eight-hour law was enforced in that state, the loss of time to the companies due to this habit amounted to over seven per cent. To break this habit by force meant spotting and nagging, an odious and generally unsuccessful way of dealing with men. A simple remedy was found in the erection of a change house outside the mill. Orders were given that no clothes were to be left hanging in the mill and that no man should leave his machine until relieved by the next shift. The men appreciated the new change house and took kindly to the new rules.

Smoking

Whether smoking is or is not an objectionable habit is a question on which management and crew have often opposite views. Two arguments are brought against smoking; one is the general idea of discipline and the loss of time caused by the repeated lighting of a refractory pipe; the other is the danger of fire.

Against the first argument I will say that even the most unremitting worker will every now and then straighten up to stretch his back, and that it seems unfair to deprive a man of the satisfaction

of a smoke when he has wiped the grease off his hands after accomplishing a stiff job. As to the discipline, I do not believe that it is much benefited by the enforcement of a rule which is generally considered vexatious and therefore frequently transgressed even by the most reliable men in the mill. A 'super' noticing one of his best men having a smoke on the sly must either fire the man for a truly menial offense or allow discipline to slack by not enforcing the rules. Where Mexican labor is employed, the rule has some reason of being, as a Mexican is liable to give precedence above all other things to the rolling of his cigarette, when the psychological moment to do so has arrived.

The Danger of Fire

As to the danger of fire; I will say that the only danger lies in the possibility of some one throwing away a lighted match. To build a fire with wood shavings and a burning cigarette is a very difficult undertaking, as you can convince yourselves by trying it.

The sources of fire in a mill can be better explained to you by an insurance agent than by me. However, in two instances have I seen a fire start under conditions that were the results of defective arrangements of the mill.

In one case a wet 'jumper' had been placed on a radiator to dry; some matches in one of the pockets came in contact with the steam coils and, when the clothes had become dry, the matches ignited and the whole thing burst out into flames. I have given this example to emphasize the necessity of providing change-rooms for the men as a measure which, besides being a protection against fires, offers also many other advantages.

Another source of fire is the inveterate use of the miners' candlestick in and around the plant. It is natural that a workman must be able to see to do his work, and therefore, if the designer of the mill or the superintendent does not provide good and practical ways of illuminating every part of the mill and machinery, the millman will have recourse to the primitive but always effective candlestick. Eventually the candlestick will be jabbed into a post and forgotten, until the 'snuff' burns its way out of the socket and falls to the ground.

In a fire of any kind, it is the immediate action of a few that counts more than the action of many later on. Generally there are only a few men, even in a large plant, and these men must be drilled so that their efforts will be applied to the best advantage. It is well, therefore, to entrust certain specific duties to the men employed on certain jobs. As example: the table-man is to give the general alarm, the jig-man to open the water supplies and cut off the water wheels; others to play out the hose, and so forth. If these actions are not preconcerted it will be found that invariably the same idea of what is most important to do will loom in several minds at the same instant, and several men will be running for the alarm whistle, whereas one man is entirely sufficient to perform this duty.

All this may sound very commonplace and self-evident, but I know that there is not one plant in ten where such precautions are planned and the men

drilled into fire brigades. After the fire is over, everybody complains about the great confusion that took place.

More difficult than the abrogation of a few bad habits is the reforming of an organization that for some time has been running down and losing the right spirit that leads to high standards. A reform of this kind may take considerable time, as bad habits are more easily acquired than lost. Once, however, that a certain standard has been established, it is not hard to maintain it; all that is necessary is to keep up the right spirit between the men and it is remarkable how appearances and items of comparatively small importance may be of great consequence in keeping up this spirit.

The factors affecting the spirit of a mill crew may be moral or material ones. The first ones can be summarized in the words, 'interest in the work.' They are the friendliness existing between the management and the crew, the spirit of emulation between one shift, or one crew, and the other, and the interest taken by the management in the work. If a mill-crew feels that its good work is not noticed and appreciated by the management it becomes discouraged and ends by not caring whether the work is done well or not as long as the mill is kept running and the job holds out.

The Value of Posting Assay Returns

To keep up the interest of the men it is necessary to keep them posted of the daily assay returns, as without these the men are absolutely unable to gauge their own work. There are some mining companies which still maintain the time honored prejudice that there is much wisdom in secrecy. If the mill losses are heavy there is no use of hiding the fact, as any outsider really interested to find out this point, will succeed in doing so by direct or indirect means, and the losses cannot be concealed from the men who operate the plant, as they are better aware than anybody else of what is right and what is wrong in the plant. More so, secrecy is in general responsible for an unfavorable public opinion, and is the source of many exaggerated statements and much unjustified gossip. The companies which have adopted the policy of posting daily all mill assay returns in broad daylight have never, to my knowledge, had occasion to repent of having done so. On the other hand, I have often listened to the complaints of millmen who, owing to the system of secrecy in force, were absolutely unable to gauge their work and improve it. There is nobody to whom an assay means more than to the man who was operating the machinery at the time the sample was being taken; he knows the conditions existing at that time and the meaning of the assay returns. The daily returns give him means to judge the quality of his work from the appearance of the ore on the machinery and to establish relations between cause and effect that would escape even the eye of the superintendent.

Besides this, there are many other factors, some of apparently little importance, others only indirectly connected with the operation of the plant, that materially affect the spirit of the men and the efficiency of operations. The question of light is one of vital importance; whether natural or artificial, a good

illumination is instrumental in imparting a spirit of activity, buoyancy, and contentment that can be understood more easily by thinking of the feeling of depression one has when obliged to work in a gloomy place. In addition to this, good illumination not only helps and even is necessary in the performance of good work, but it brings also in evidence all failures and defects; the men will be more painstaking just because their negligence will be more apparent.

Cleanliness of the Mill

So also the general cleanliness of the mill is a most powerful factor in keeping up the spirits of the men and in insuring the healthy life of the machinery. You can be sure that in a plant where the floors are clean, where the windows have been washed, where small repairs are not made with patches, oakum, and electric light wires, it will also be true that the machinery will be in good shape and in good adjustment, and that the metallurgical efficiency will be high. Where a plant is expected to be kept spick and span the designer and the management must do their share in arranging the plant so that everything can be kept clean. If the management makes serious efforts in this direction by repairing against the sources of uncleanness, it can exact from the men a strict observance of the rules, but where the cause of the trouble lies in some congenital defect of the plant it is impossible to expect the men to devote a good part of their efforts to cleaning.

Some of the modern ore-dressing plants have been carried to such a degree of refinement, you could almost say of comfort, that they have been subjected to criticism. In these plants some details may have been carried too far, but in a general way I believe that the capital invested in refinements will bear return interest in reducing the cost of operation and increasing the metallurgical efficiency. To understand the far-reaching importance of these refinements it is best to consider the effect of reversed conditions.

In most old plants, and even in some new ones, you will find some machinery which has become the 'Cinderella' of the plant. Generally it is a piece of machinery that has been squeezed in some forsaken hole as a make-shift, very often to repair some error committed elsewhere or to bear the burden of insufficient foresight. Whenever this happens, it is almost hopeless to prevent the machine from degenerating to the last stage to which iron and steel can fall, and all that is asked from the machine is that it should be gracious enough to keep on running so that other parts of the plant may operate undisturbed. In such cases the irritation caused by perennial troubles, destroys all feeling of friendliness, and, instead of care, the machine receives little else but oil and cuss-words. To repair such a state of affairs it is useless to reproach the men; the odious conditions have spoiled their spirit, and the only remedy is a radical change.

These conditions lead us to another item—I should say to the item—where the human element must be remembered, and this is the designing of a plant. Our friend, T. A. Riekard, in his numerous papers on technical writing reiterates, "Remember the reader." In the same way the engineer who designs an ore-dressing plant should repeat to himself,

"Remember the millman." The general principles governing the design of a plant, I will take up some other time. What I wish to emphasize now is that an engineer in deciding about the general arrangement of the mill, the spacing of the machinery, the distribution of the floors, the division of buildings, and so forth, must constantly keep in mind the fact that the plant is going to be operated by human beings. These human beings are going to be the prime movers of that great living, pulsating organism that is a modern ore-dressing plant; they are the governors that control and balance one part with the other. These human beings are the most important pieces of machinery in the whole plant.

This all-important human side of the mill design cannot be studied at school; it is only by practical experience, chiefly by the repeated method of committing errors, that we learn this difficult art of what men will do under given circumstances. To analyze this question thoroughly would lead us too far; a few examples will illustrate the principles.

First of all, a human being is only capable of a certain amount of physical effort and mental strain; if overtaxed beyond this limit, a man will instinctively lighten the load by shirking work and neglecting things; if not kept sufficiently busy a man feels unhappy and becomes lazy. The mill, therefore, must be so arranged as to allow of an equitable distribution of labor. All operations ought to be made as easy as possible because the greater the ease the more care can a man bestow on his work and the greater the volume of work that can be entrusted to him. As an instance: where a table floor is arranged in such a way that the operator can see at a glance the operation of many machines, one man can operate a greater number of tables than when the tables are distributed irregularly and on different floors. The men must not be distracted from their work and therefore it is essential that none of the secondary or subsidiary machinery of the plant should ever become the source of trouble.

Arrangement of Equipment

Launders, feeders, pipes, transmission machinery, and so forth do not perform selective work of any kind; they are supposed to operate without requiring intelligent attention, and if any of these mill-parts give trouble the men are distracted from their more important duties, that of watching the machines where the money is earned. A good illustration of this are launders which, owing to insufficient grade, are affected by chronic congestion. A launder of this kind will periodically call the men away from their work and thoroughly disgust them by necessitating frantic efforts that are absolutely uncalled for and which could have been avoided by more foresight and care.

Not only ought operations to be made easy, but everything ought to be arranged in such a way that any work may be performed without personal discomfort. As example, if insufficient space is left under some machine or if the space is wet, dark, and dirty, you can be sure that the men will let things go pretty well to the bad, before making up their minds to crawl into that ugly hole for making necessary adjustments and repairs.

In a similar way the provision of good facilities for adjusting the concentrating tables, will increase the economic efficiency of the mill; where the exact division of concentrate from middling, and middling from tailing can be attained by simply shifting with one finger a galvanized iron splitter, these small adjustments will be done more frequently and more carefully than if the operator has to crawl below the machine to tilt the table.

In one mill I had occasion to study, the building was poorly designed and constructed for a cold climate; in addition to this the table floor was heated by one solitary radiator which was in proximity to none of the machines and during the cold winter nights the millmen would huddle together around

the only warm place in the plant, almost completely deserting their machines. The removal of this friendly radiator to a more central position greatly increased the mill efficiency during the cold season.

The various aspects of the human side of the milling that I have mentioned may give an idea of how more could be said about this subject; to cover the ground more extensively would be straying too far from the traditional curriculum of ore-dressing.

Many of the statements made may appear commonplace, but it is astonishing to see how many of these commonplace principles are either ignored or disregarded in practical life.

The human element is the prime mover of everything. More so, it is the fundamental basis of success

or failure in life. The men that have succeeded are the men who have known how to handle men, and it is my conviction that a man's success in life depends far more upon his knowledge of human nature than upon his fund of human knowledge.

The Coeur d'Alene Mine-Car

By ULYSSES B. HOUGH

Above are presented scale drawings of a centre-dump steel mine-car used in the Coeur d'Alene lead mines of Idaho. The mines of this district are opened by means of adits extending three to six miles into the mountains, and electric locomotives are used for haulage. Ordinary mine-cars are not adapted for this service, being too light, of too small capacity, and requiring too much time for unloading. The car illustrated weighs 2200 lb., has a capacity of 49 cu. ft., and costs \$105 to \$225, depending upon the exact method of construction. The body is made of 1/4-in. steel plate put together with 1/2-in. rivets. All bolts are of 3/4-in. diameter. The figures show side and end elevation with cross and longitudinal sections.

The Rand Banket—Part VI

By C. B. HORWOOD

The particular banket series chosen by the mineralizers as maximum channels of circulation, in which deposition of their gold and pyrite has occurred, and the reason for such selection, has been discussed. The extension of the gold contents both along the direction of the strike of these beds of conglomerate and in depth has also been considered. The distribution of the gold as between the various members of the series has been described; also the fluctuations in the amount of the gold contents between the two leaders, which represent the profitable seams of the two subdivisions of the series.

It will now be well to review the question of the much-discussed and sometimes disputed presence of 'shoots', and of local enrichment due to dikes. Afterward, mention will be made of some of the local indications of relatively rich ore in these lodes.

The Occurrence of Shoots

Weed believes that the satisfactory explanation of the occurrence of ore-shoots is one of the most difficult problems in the study of ore deposits.²⁴⁵ Posepny showed that fissures do not provide, throughout their entire length, spaces of uniform width, and that only those portions remaining open permit active circulation of solutions and regular deposition from them; hence, at obstructed parts there would be either no circulation or only a sluggish one, thus explaining how on the same vein-plane rich deposits alternate with poor or barren zones. He stated that "from the genetic standpoint, the richer portions are interesting as sometimes occupying more or less regular belts in the vein-plane, called 'channels,' 'shoots,' 'chimneys,' etc." These names evidently designate the main channels through which the mineral solutions passed; and the occurrence of such forms in most kinds of deposits tends to prove that, notwithstanding other differences, they were all formed in a similar way."²⁴⁶ From the facts already enumerated and from what follows it will be sufficiently clear that the gold deposits of the Rand form no exception; to them also the same reasoning can be applied.

As already emphasized when dealing with the extension of ore along the direction of the strike and with the fluctuations in yield between the two leaders (which represent the principal gold-carriers of the two sub-series of banket), fairly regular alternations between rich and poor ground occur along the strike, and these extend in depth. The extensions in depth are generally not at right angles to the line of strike; they have more or less pitch; that is, the rich or poor ground, as the case may be, has a trend that forms an angle with the line of strike.²⁴⁷ This angle is almost invariably greater than the one made with the direction of the dip of

the banket; that is, in nearly every case the direction of the longer axis of the orebody is downward, rather than parallel to the line of strike of the banket. The definition of a 'shoot' is an orebody that forms a sort of continuous column.²⁴⁸ Experience has shown that these columns die out eventually in depth. Gregory²⁴⁹ has tried to maintain that, in the Rand conglomerate, the gold exists in patches and not in shoots, as is proper in a placer deposit, whereas if the gold were introduced by filtration it should be present in shoots. His attempt is far from convincing, nor has he defined his terms. Marriott,²⁵⁰ who maintains that the gold does not occur in shoots, has stated that "the consistently richer portions lie in a series of irregularly shaped areas of which the units can be observed as measuring roughly up to five thousand feet by two thousand five hundred feet on their major and minor axes."

The context indicates that he admits that the major axes make the lesser angle with the direction of the dip of the banket. The attempt to distinguish between 'patches' and 'shoots' seems somewhat labored. Whichever they are termed (although, according to the amount of pitch, they may course more or less diagonally across the banket beds), their general direction is downward, and therefore they come under the definition of 'shoots.' Richard Beck,²⁵¹ in discussing Gregory's paper, said that the argument based on the difference between shoots and patches seemed to him to prove very little, as in true quartz veins, as well as in placers, there are areas that are either elongated in one dimension and are termed shoots or channels, or of irregular shape and termed patches. J. Malcolm MacLaren²⁵² pointed out that in actual mining practice no distinct line of separation could be drawn between patches and shoots. He rightly said that "if the presence of patches rather than shoots were admitted as a sufficient criterion of the alluvial deposition of gold, then many of the world's richest gold mines, for example, Waihi and Mount Morgan, must be grouped under the heading of alluvial deposits. Certainly, so far as might be judged from the literature of the subject, there appeared to be more evidence in favor of shoots on the Rand than in either of the mines mentioned." De Launay²⁵³ stated that the theory that the gold was formed after the bankets would afford a good explanation for "the variations in the grade of the ore, as it is observed in following the line of the outcrop from one claim to

another, and likewise the relative uniformity of zones, rich or poor in sinking on the dip, while the placer hypothesis would appear to require a uniformity along a line parallel to a primitive coast and a progressive decrease in richness as distance is gained transversely to the shore line." The general direction of the pitch is not always the same; it varies in individual cases. For example, there is a distinct shoot of relatively high-grade ore, which might be termed the York-Luipaard's Vlei shoot, which was formerly worked in the York mine. It trends from northwest to southeast into the Luipaard's Vlei mine and has a pitch of about 40 degrees.²⁵⁴

The Shoot on the Near West Rand

Another well known example of a shoot of good ore occurs on the near West Rand. This has a pitch to the southwest and runs from an outcrop mine into a neighboring deep-level. Some of the best examples occur in the Nigel district. The successful operation of the Nigel mine depends on the presence of shoots of good-grade ore.²⁵⁵ These are admitted to be 'shoots' even by the most ardent disbeliever in the presence of shoots on the Witwatersrand proper. The Nigel Reef series is held, with good reason, to be the same as the Main Reef;²⁵⁶ if this be so, then the existence of shoots must be admitted for the Witwatersrand also. On the Central Rand, the rich ground of the Pioneer and Robinson outcrop mines extended in depth into the Bonanza and Robinson Central Deep mines and passed again in depth into the Robinson Deep; this surely partakes of the ordinary nature of a shoot? Gregory²⁵⁷ admitted that J. Hays Hammond referred to "unquestionable evidences of ore-shoots in the Nigel and Rietfontein mines"; and that Hatch and Chalmers maintained that "there are instances of distinct shoots in the New Rietfontein, the central portion of the Simmer & Jack, and in the Meyer, Leeb, and Orion properties." Gregory pointed out that the bankets in the New Rietfontein mine and at the Meyer and Orion mines are not those of the Main Reef series. Although those at the former belong to the Du Preez series and those at the two latter mines to the Black Reef formation,²⁵⁸ yet in every case they are conglomerate beds. It has already been shown in this paper that the mineralization in the first of these cases was doubtless contemporaneous with that of the Main Reef series; and later it will be shown that the gold in the Black Reef conglomerates was also, in all likelihood, introduced at the same time.²⁵⁹ Therefore this dis-

cussion applies in these instances with equal force. E. J. Way²⁶⁰ has stated that in the Kleinfontein mine there are five distinct shoots, which vary in width from level to level; that the company's system of development was based on their presence; and that it was known from level to level, as depth was gained, approximately to within a few feet, where they would be encountered. The writer's experience, as a mine manager on the Rand, is that in almost every mine there are shoots, that is, more or less vertical stretches, of ore of relatively higher grade than the average for the mine; their presence influencing both the development and stoping policy. In consequence of the physical nature of the beds (which have been appropriated by the mineralizing solutions in preference to ordinary fissures), including their great extent along the strike, the more or less vertical columnar orebodies of higher grade are often much larger than is usually the case in normal fissure-veins. When the ground between such zones on the one 'reef', or layer of banket, is poor or unprofitable, the yield of that portion (lying opposite to it) of the other parallel seam frequently compensates for this; consequently, less attention is attracted to the fact that richer and poorer columnar masses exist than would be the case were these mines not twin mines but merely dependent on one lode alone.

The Influence of Dikes

Gregory,²⁶¹ in discussing the connection of gold ore with the dikes, admitted that "if a connection between the dikes and the ore values had been established for the Rand as a whole, the fact would have given powerful support to the infiltration theory." He then quotes J. Kuntz as having maintained that the banket was the richest in the proximity of dikes. He admitted that, in places, the dikes have influenced the enrichment; he described an example in the case of the Worcester dike and stated that a similar case occurs in the Ferreira mine. He also quoted a case of enrichment between the arms of two dikes in the Meyer & Charlton mine.²⁶² Further, he admitted cases in which faults appeared

a lode formation of hydrothermal and deep origin of a special type. The Rand ore deposits being a simple but particular case of the type of deposit represented by the various formations, of South Africa, which carry gold-bearing pyrite. They have been produced under pressure and in depth by mineralizing waters from an eruptive magma; and, during the intrusion of the ancient granite, or during the period marked by the Black Reef, or even much later, a far-reaching emanation of sulphide waters must have affected different geological formations, throughout South Africa. He pointed out then that there were those, on the Rand, who admit a relationship between the gold and the basic dikes. Since De Launay wrote this, it is now known that the Witwatersrand beds are younger than the ancient granite, on which, and the Swaziland series, they were laid down; and, therefore it is not to this ancient granite that one must look for the source of these emanations.

²⁵⁸G. Denny in his book, 'The Klerksdorp Goldfields,' pp. 141, 175-176, and 184, speaks of shoots in the Black Reef banket in the Klerksdorp district.

²⁵⁹L. De Launay, ten years ago, pointed out that if the gold was formed since the conglomerates, then also the advent of the pyrite must have been subsequent to the deposition of the banket beds, so that we have to deal with

to be connected with the deposition of gold, and gave an example. In face of all this, he then attempted to minimize the importance of such cases and said that similar differences could be seen in places as near together, and not separated by a fault, as those sometimes recorded in the assays on the two sides of a dike or fault. He maintained that "the sudden differences in value of the reef on two sides of a dike or fault may be due to movements long after the deposition of the gold. Many of the dikes have been introduced along fault-planes, and the faults have shifted the country, bringing patches of barren reef against patches of rich reef." If the displacement produced by the main faults and dikes that have influenced the distribu-

tion of rich ore were in a lateral direction, this reasoning of Gregory's might have some weight.

with dikes are sometimes crowded with well formed crystals of pyrite." He illustrates his remark by a micro-photograph showing chloritized banket from the Main Reef Leader near its contact with a basic dike in the Robinson Deep gold mine; and the close association between the pyrite and gold in the banket has already been discussed in this paper. Denny,²⁶⁵ writing of the Buffelsdoorn 'reef', near Klerksdorp, stated that the gold in this banket was confined within a recognized distance of a dike, maintaining throughout a well defined parallelism, and beyond this limit there was no profitable ore. Truscott,²⁶⁶ commenting on this, points out that the presence of the gold is thus evidently due to the dike, which he says is either a portion of the diabase underlying

FIG. 28A.

The Main Structural Faults

The main structural faults are parallel to the strike of the beds and have been produced by pressure exerted at right angles to this strike; and the longitudinal dikes intruded as a result of the fracturing and faulting are also parallel to the strike of the banket beds. Reversed faulting²⁶³ has ensued, producing vertical displacement of the beds, with, generally speaking, little or no lateral displacement. So Gregory's argument does not hold. Moreover, there is often distinct enrichment of the banket on both sides of a dike. Numerous instances of this are known; for example, those associated with the Ferreira-Crown Deep dike. A. D. Bacon, formerly general manager of the Langlaagte Estate and Langlaagte Block B. mines, told the writer that there was distinct enrichment on both sides of the Ferreira-Crown Deep dike in these mines, and that it continued for two levels on the south side of the dike. An enrichment due to the Crown Reef dike has already been described in the first part of this paper in connection with the occurrence of pyrite 'pebbles' in the Crown Reef mine. R. B. Young²⁶⁴ states that "banket and quartzite at their contact

the Black Reef formation,²⁶⁷ or is a separate intrusion lying closely under that diabase. An example, in the Worcester mine, at Johannesburg, to which Gregory refers, had been described by J. Hays Hammond.²⁶⁸ He speaks of the dike as being in the upper levels immediately above the Main Reef Leader and there the hanging wall portion was very much richer than the foot-wall portion of the banket, and maintained this character until, in the lower levels, the dike, having cut across the banket, formed its foot-wall, when the gold contents were found on the foot-wall side of the reef. Truscott²⁶⁹ also refers to this case. Hammond²⁷⁰ also mentioned an interesting occurrence in the Ferreira mine, at Johannesburg, of a dike containing a considerable amount of visible gold. This dike was below the South Reef and separated from it by several inches of vein-quartz, which was auriferous. Associated with the banket beds, sometimes following, sometimes crossing the formation, or intercalated with the banket, were numerous quartz veins, which usually carried little gold, but in places were very rich. Many of the quartz pebbles were cracked, but had been re-cemented by secondary silica. Films of gold were frequently found along these cracks. Truscott²⁷¹ also described this occurrence. The distinctly

²⁶³This reversed faulting has produced an up-throw, or upward displacement, of the beds on the southern side of the east and west, or longitudinal dikes. The vertical amount of displacement is often as much as 250 ft. By such faulting the tonnage of ore per claim-area is increased.

²⁶⁴R. B. Young (1909), *loc. cit.*, p. 89.

favorable influence exerted by the big longitudinal dike, known as the West Reef dike, on the ore in some of the Randfontein mines was pointed out by the writer in the second part of this paper. This case is somewhat similar to that in the Worcester mine, on the Central Rand, inasmuch as the upper

These stopes are terminated on the south by what has been termed in these mines the 'main up-throw fault.' The figures on these plans represent the approximate assay-values in pennyweights per ton (as taken from the stope-sheets) of the various portions of these workings. In every case the sections

FIG. 28B.

FIG. 28C.

portion of the West Reef is richer where immediately overlain by this dike. Where the dike is absent the foot-wall portion is the richer. The accompanying Fig. 28A, 28B, and 28C represent the plans of three stopes in the central section of the New Rietfontein Estate mines. The western one, seen in Fig. 28A, is on the 8th level and is 630 ft. vertically below the surface; the central one (Fig. 28B) is on the 7th level, at a vertical depth of 550 ft., and is 900 ft. east of the one in Fig. 28A; and the eastern stope (Fig. 28C) is on the 6th level, at a vertical depth of 470 ft. and 500 ft. east of that in Fig. 28B.

through the stopes are as shown, diagrammatically, below:

That portion of the lode that is illustrated in the above sketch by a shading invariably has an assay-

value of from 20 to 60 dwt., irrespective of the yield in the northern, upper, portions of the stopes. This fault can be clearly traced for a distance of about 5000 ft., and in every stope its effect was similar to that in the three just described.²⁷²

Transverse Dikes

The numerous transverse dikes observed in the mines of the Rand are of later date than the longitudinal or strike dikes, as is evident from the fact that the latter are often faulted by the former. As already mentioned in a footnote in the third part of this paper, these transverse dikes mark the position of radial fissures, which constitute one of the features obtaining around centres of igneous intrusions, and which are really contraction-cracks due to the cooling of the igneous mass. When such fissures extend in depth to the molten magma they are filled, and dikes result. Consequently these transverse dikes are, in all probability, of only slightly later date than the longitudinal ones, which are also due to the contraction of the igneous mass. In some cases, with which the writer is acquainted, they have produced distinct enrichment of the neighboring banket; but the longitudinal dikes have, speaking generally, certainly exerted a far greater influence in this respect; and although they have not invariably affected the richness of the ore, yet it seems reasonable in mining to expect that the gold contents may be affected by these dikes; and the experience of the writer has been that they usually are affected either on one or both sides of the dikes. A connection between these longitudinal dikes and the gold contents has now been sufficiently established for the whole Rand.²⁷³ Where there is no reason to believe that the gold was originally deposited elsewhere and has since been dissolved and re-precipitated, a thin film of gold is sometimes found on the surface of these longitudinal dikes,²⁷⁴ clearly indicating that the deposition of the gold occurred after their intrusion.

Local Indications of Good Ore

Gregory²⁷⁵ rightly asserted that mining engineers on the Rand claim to have noted a connection between the richness of the banket layers and their physical characters, and that they can often distinguish at sight between rich and poor ore. Locally, managers and mine foremen, if the ore comes from their own mine, can tell by its appearance whether it is rich or poor. Few, however, have sufficiently analyzed the reasons why they are able to do so, to be able lucidly to explain the characteristics indicating good ore. Gregory argues that these fea-

tures are those connected with the original deposition of the conglomerate and consequently support the hypothesis of a detrital, or placer, origin of the gold. It will, however, be seen from what follows that only the first mentioned of the many characteristics, to be described, is connected with the original deposition of the banket; the remainder are due to causes that have operated since the conglomerates were formed, and probably late in their history.

(a) *Large Pebbles*.—Gregory, after quoting the following from Becker,²⁷⁶ "It is well recognized on the Rand that, other things being equal, the coarser pebble carries the greatest quantity of gold," goes on to say: "Prister²⁷⁷ reports that it is the opinion prevailing among mine managers that conglomerates with big pebbles are a good indication of gold, an opinion which is often confirmed." Gregory then states that this was the late Wager Bradford's²⁷⁸ experience in the Langlaagte Deep mine; and also Fred Hellman's²⁷⁹ in the East Rand Proprietary mines. He then states that "taking the mines along the Rand, the occurrence of big pebbles is generally regarded as favorable to the existence of good ore values," with which statement the present writer entirely agrees; but he does not agree with Gregory that in this case it is an argument in favor of the placer theory.

That the conglomerate beds were more easily permeated by the mineralizers than the sandstones has already been shown; and, in the same way, other things being equal, the larger the pebbles of the conglomerate the easier the channel presented to ascending, deep-seated, mineralizing solutions. This directly explains the frequent association, in the banket, of large pebbles with rich ore. The Main Reef Leader often contains large pebbles, up to 4 and sometimes as much as 6 or 7 in. long, and one can then rely upon its good grade. It is an excellent example of the occurrence of large pebbles in conjunction with rich ore.

(b) *Much Pyrite*.—Other things being equal, the presence of more than a usual amount of iron pyrite in the banket is usually, though not invariably, an indication of good ore. This is only what one would expect, since the gold of the banket is to a large degree mechanically bound up in the pyrite.

(c) *Pyrite 'Pebbles'*.—In the first portion of this paper, it was demonstrated that these 'pebbles' are in every case metasomatic products, formed after the deposition of the banket by metasomatic agencies similar in all essentials to those familiar to us in the case of normal fissure-veins. The invariable association of the so-called 'pebbles' of pyrite with good ore was considered of such importance, in relation to its bearing on the origin and period of the gold deposition, that it was separately dis-

²⁷²The above details and diagrams, in connection with this fault in the Rietfontein mines were given to the writer in 1911 by F. Graham Bell, who was then general manager of these mines.

²⁷³In the case of a goldfield like the Rand, where the mines are being actively worked and so many interests are involved, there are obvious reasons why all the examples with which one is acquainted cannot, at the present time, be quoted.

²⁷⁴The writer has found good examples of such occurrences; and in some the films of gold exhibit four slickenside surfaces, demonstrating that some movement has occurred after its deposition.

²⁷⁸Wager Bradford was, at the time of Gregory's visit to the Rand, manager of the Langlaagte Deep mine.

²⁷⁹Fred Hellman was general manager of the East Rand Proprietary mines.

cussed in Part IV of this paper. It might be well to call to mind that it was then shown that the gold and pyrite were introduced into the banket after the intrusion of the dikes. Further, it was indicated that the intimate association of the gold and pyrite and the fact that the pyrite replacements are a sure indication of gold, suggest that both were deposited from the same solutions, in which possibly they may have been present as a eutectic mixture; and, if so, the difficulty of imagining the high temperatures otherwise necessary to vaporize the minerals and metallic elements of veins would at once disappear.

(d) *Carbon*.—The presence of carbon in the ore is an almost certain indication that it is of good grade. The first detailed account of its mode of occurrence in the banket is that by R. B. Young,²⁸⁰ who described it as being found in small, black, opaque nodular grains; having a somewhat warty dull surface, and ranging in diameter from one millimetre downward, sometimes blending together into a compact mass of anthracite appearance. He mentions that at the Rietfontein mines it occurs not only in nodular grains, but also in veinlets, up to two millimetres thick, with a columnar structure, the columns being perpendicular to the walls; and, between the columns, thin films of sericite are generally present.

Distribution of Carbon

He states that in his specimens the carbon lies along, or close to, a parting, generally a bedding-plane, but in some cases a crack oblique to the bedding, and that the carbon is frequently wholly or partly embedded in secondary quartz. After calling attention to the association of gold with carbon, he remarks: "There are features in the distribution of carbon in the bankets and associated quartzites which suggest that it may not have been an original constituent of the rocks in which it is found, but was introduced at a later date. This, however, requires a fuller investigation than I have been able to give it." He then adds: "The association of graphite with gold in some of the Australian goldfields is well known. In the Croydon goldfield, in Queensland, the auriferous quartz veins are found in a much disturbed and altered zone of granite containing graphite." George G. Holmes²⁸¹ informed the present writer that in the Buffelsdoorn mine, near Klerksdorp, the carbon occurs in small granules a foot or so above the foot-wall of the gold-bearing quartzite, and scattered over a distance of some feet, and that when carbon is present the quartzite generally contains good gold values whether pebbles are present or not; for instance, there are places where assays give 1 to 1½ oz. of gold over about 6 ft. and where no pebbles occur, but small granules of carbon are scattered through the rock. The carbon also occurs in small veinlets up to ⅛ and ¼ in. wide. There, experience has proved that carbon is a sure indication of the presence of gold. Carbon can be detected in the ore

that is mined in probably most of the mines along the Rand; but only in a few is it sufficiently in evidence to be a characteristic feature. These are the Rietfontein mines, on the East Rand, and the Randfontein mines on the far West Rand. Carbon occurs also in noticeable quantity at the Buffelsdoorn mine, and in the Black Reef banket at the Machavie mine, between Klerksdorp and Potchefstroom. Gold can be found not only as a film on the particles of carbon, but it has also been observed, by the writer, actually imbedded in the carbon; he has also seen in Rietfontein and Randfontein specimens the columnar structure (which Young noticed in the carbon) in both gold and carbon, the former being enclosed within the latter. In examining under the microscope thin sections of banket showing carbon from the Carbon Leader and Buckshot Reef from Rietfontein, from the Randfontein Leader, and from Buffelsdoorn, the writer found that the most noticeable features are the intimate association and intergrowth of the carbon with gold, the latter not only frequently lying round the carbon grains, but also occurring as particles entirely surrounded by carbon, while the carbon grains often contain minute specks of gold scattered through them; the frequent and close association of the carbon and pyrite, which is particularly noticeable in the Buckshot Reef; and the frequent association of sericite with free gold and carbon. These facts, together with the presence of carbon in small irregular spheroids (frequently, owing to the way it is imbedded in the matrix, resembling circular flat flakes) scattered through the matrix of the banket, but more abundant along its immediate foot-wall; and, further, its almost invariable presence in close association with 'buckshot' pyrite, when the latter is present, cannot well be explained by any theory of organic origin. When subjected to destructive distillation, the writer found that the carbon yields traces of oil, indicating the presence of hydrogen in other form than in combination with oxygen as water. The writer's investigations showed that, in some cases, when heated in a closed tube, it swells up like sprouting graphite, and vapors are evolved that have a characteristic smell, and these, on cooling, condense as oil on the upper portion of the tube. In both cases the presence of hydrocarbons is suggested. Having made a careful study of the occurrence of carbon in the banket in those mines of the Rand where it is most typically developed, the writer, some few years ago, embodied the results of his investigations in a paper;²⁸² while it was going to press, R. B. Young²⁸³ called attention to the relation of the carbon to the quartz in the matrix of the banket as suggesting that the carbon had, in some instances, replaced quartz; he had observed carbon in the pebbles in banket specimens from the Meyer & Charlton mine and from the Bon Accord mine; although it was generally in the neighborhood of cracks, it did not occur as a filling of these, so he (Prof. Young) con-

²⁸⁰R. B. Young (1909), *loc. cit.*, p. 86.

²⁸¹George G. Holmes was at the time (1910), manager of the Buffelsdoorn mine. This is a banket mine about 70 miles southwest of Randfontein.

²⁸³'The Replacement of Quartz by Carbon in the Rand Banket,' by R. B. Young, *Trans. Geol. Soc. So. Af.*, Vol. XIII (1910).

cluded that it had replaced portions of the quartz of the pebbles. The present writer referred to this in a footnote in his paper and pointed out that similar conditions were exhibited by some of his own specimens and that in slides from Buffelsdoorn specimens and from the Carbon Leader from the Rietfontein mines the rounded grains of carbon appear sometimes to be intergrown with the quartz granules of the matrix, the latter being in some cases invaded by the carbon; and that in one of his hand specimens of the Leader from the North Randfontein mine an irregular grain of carbon, varying from one-sixteenth to one-eighth of an inch in thickness, with a thin leaf-like layer of gold around its edge, can be seen distinctly embayed into the edge of an oval-shaped light-gray quartz pebble of regular outline. Carbon can also be found in the body of a pebble where no cracks are to be seen, as the writer has observed in the Rietfontein Buckshot Reef and in the Randfontein Leader. This points to a portion of the quartz of the pebbles having been metasomatically replaced by carbon, even as it has been already shown that the quartz pebbles have, in some cases, been so replaced by pyrite; and it strongly suggests the agency of active magmatic vapors. In this paper (in 1910) the present writer traced the genesis of the carbon to the agency of the neighboring diabase dikes, which by numerous analyses he found contained carbon in appreciable amount.²⁸⁴ From one dike, about 5½ ft. thick, he had samples taken from the centre 12 inches in the main cross-cuts, in the mine, from the 2nd down to the 15th level (both inclusive); that is, at distances apart of about 160 ft. over a total inclined length of 2080 ft., and between the vertical depths of 190 and 2090 ft. The result was that, except in two cases where only traces were present, carbon was found in quantities varying from 0.02 to 0.22%. He concluded his investigations on the genesis of the carbon with the following remarks:²⁸⁵ "Its occurrence is closely associated with that of the pyrite and gold and indicates a close relationship between its presence and that of neighboring igneous rocks, which have, in the foregoing pages, been shown to contain carbon. It is difficult to account for the way the carbon occurs in tiny spheroids scattered through the matrix in Rand bankets other than that it was deposited from gaseous or very mobile liquid hydrocarbons, in a similar manner to that of the carbon mineral at the Mary mine as described by Kemp,²⁸⁶ before the final cementation and indu-

ration of the bankets by the deposition of secondary silica; and, taken in conjunction with the known facts of its occurrence in other parts of the world, it is perfectly reasonable to attribute its origin to magmatic vapors or solutions derived from the neighboring basic igneous intrusions before their final solidification."

Source of the Carbon

One critic, in discussing²⁸⁷ the writer's paper on the carbon in the bankets, admitted that he (the writer) had demonstrated that carbon occurs in the dikes; and further admitted that it must have been precipitated from some substance capable of finding its way along most minute cracks, but he (the critic) argued that it was not proved that the dikes were the source of the carbon, because, as he suggested, the carbon may have been introduced into both dikes and reefs from some other source.²⁸⁸ Those who have made a careful study of ore deposits are agreed that the igneous rocks are the ultimate source of the metals; and, in studying any particular ore deposit, unless there is excellent reason for believing otherwise, if the same minerals are found in neighboring igneous rocks they are satisfied to ascribe the source of the minerals in the deposit to these rocks. The researches of numerous investigators (such as Armand, Gautier, Edouard Suess, Brun, Chamberlain, Weinschenk, Osann, and Kemp) have proved beyond question the abundant presence of deep-seated carbon and hydrocarbons in the earth's interior, therefore the same reasoning applies in the case of this carbonaceous matter as in the case of the metallic minerals of an ore deposit. In his paper the present writer pointed out that Kemp traced the origin of the graphite, or some closely related carbon-mineral, at the Mary mine to the agency of some gaseous or very mobile liquid hydrocarbon which had penetrated into minute cavities and had been subsequently changed to graphite; also that Walter McDermott,²⁸⁹ in writing of the Silver Islet vein, in Lake Superior, described the occurrence of silver-bearing veins associated with a diorite dike, the latter being in places strongly impregnated with graphite. The silver mostly occurred native, but also as sulphide of silver. Stress was laid on the evident connection between the deposit of the silver and the region of graphite impregnation of the wall-rock, the silver occurring where these veins traversed those portions of the dike which were impregnated with graphite. Outside the veins the graphite rock itself frequently carried silver. The diorite and the veins in it were unproductive where the igneous rock was free from graphite. Cirkel²⁹⁰ and Eugene Coste²⁹¹ have also called attention to this occurrence and to the association of graphite in mineral veins or rocks with cracks and has been subsequently changed to graphite."

²⁸⁷When owing to his absence from South Africa, he was not well able to reply.

²⁸⁵C. B. Horwood, *op. cit.*

²⁸⁶See 'The Deposits of Copper Ores of Duckstown, Tenn.' by J. F. Kemp. *Trans. Amer. Inst. Min. Eng.*, Vol. XXXI, p. 261. Kemp mentions the presence of graphite, or some closely related carbon mineral, in occasional specimens of the ores from the Mary mine, and states that it appears "to specially favor the crushed masses and was probably of late introduction. It not only forms fine leaf-like aggregates, but, in thin sections, may be detected by the microscope as minute spheroids in the midst of other minerals such as calcite and chalcopryrite. It must have been introduced as some gaseous very mobile liquid hydrocarbon which has penetrated into minute cavities and filled larger

precious metals; the former remarking that graphite seems to be connected in some way with the occurrence of silver.²⁹² Weinschenk,²⁹³ as the result of his investigations, concluded that carbonaceous matter and graphite is sometimes of plutonic origin and is formed in somewhat the same manner as cassiterite; deep-seated vapors probably containing carbon monoxide and its compounds of the cyanogen group and iron carbonyls, in the presence of water and carbon dioxide, ascended with the eruptive rocks along lines of fracture, and having become dissociated, set free the carbon to crystallize as graphite. In one locality he has proved this origin for graphite occurring in veins near the borders of a gneissic mass. Possibly a similar origin may be ascribed to the Cumberland graphite, which occurs in the basic dikes of Borrowdale.

As already mentioned in Part V of this paper, Kemp has remarked that the presence of even a small dike in any region is proof of the existence of a relatively large reservoir of igneous rock at some point beneath the surface, at unknown, but not great depth.²⁹⁴ A dike may thus be considered a channel by means of which there was at one time free communication with the underlying molten magma, which latter may be looked upon as an abundant reservoir, or source, of the metals and of hydrocarbons and other compounds containing carbon.²⁹⁵ Thus, in tracing the origin of the carbon to the longitudinal basic dikes occurring in the mines of the Rand, the results of the writer's investigations are well supported by the researches of other investigators who have worked along similar lines in other parts of the world.

(To Be Continued.)

The consumption of chrome ore is approximately 125,000 tons per year. Like many other slightly used commodities, the greater output of recent years has stimulated markets, so that the industrial uses of the metal have multiplied in a ratio sufficient to absorb the larger production. Prior to 1906 the trade disposed of some 60,000 tons of ore per year. The control was in the hands of a French group which controlled and regulated the source of the main supplies, which belonged to the Tiebaghi Company, and carried on operations in New Caledonia. The largest contributor to the world's output today is Rhodesia. It is a somewhat singular fact that the ore beds now being worked in that country were found in the Selukwe district in Matabeleland, and lie in a group of hills which have for many years been worked for gold, the output therefrom being nearly 10% of the entire Rhodesia yield.

²⁹²It is interesting that silver occurs in Rand bullion to the extent of about 125 parts per 1000.

²⁹⁴'The Rôle of the Igneous Rocks in the Formation of Veins,' by J. F. Kemp (1902), *loc. cit.*

²⁹⁵Thus the reasoning of the before mentioned critic may be likened to that of a person who seeing ice in a basin, thinks the ice in the frozen pipe and tap above it has been introduced into them from the same source as that whence the ice in the basin was derived; or, of a man who seeing coals in a truck at Newcastle concludes that the coal in the neighboring mines owes its origin to the same source as the coal in the truck.

Dredging by Hand in Siberia

By JOHN POWER HUTCHINS

In several parts of Siberia dredging by hand is now being done to recover gold or platinum from the beds of streams. The following is a description of the conditions under which such work is performed.

Conditions

The gravel must not lie in the bed of a stream having a maximum current of more than about 5 miles per hour; a faster current fills the excavation made by the scoop, and washes material out of the scoop while it is being hoisted. The maximum depth from the surface of the water to bedrock must not be more than 10 ft. If more, the length of scoop-handle is awkward, and the time consumed in hoisting reduces the capacity seriously. The gravel must be free, fine, and easily excavated; otherwise the scoop will not dig it. This method is applied extensively where there is an annual surface concentration on the bed of rivers. It is likely that it could be applied successfully in the Sacramento river, near Redding, California, where there is such concentration.

The Dredge

The dredge consists of a raft made of two sets each of 3 logs of about 10 to 12 in. diameter, and about 40 to 42 ft. long, bound together at both ends at distances of 3 and 7 ft. from them respectively. The binders are cross-logs securely mortised into the longitudinal logs. The over-all width is about 7 ft. A well about 2 ft. wide and about 30 to 32 ft. long is arranged beginning about 3 ft. from one end and extending to within about 7 ft. of the other end. The raft is anchored securely on 4 wooden spuds from 7 to 9 in. square, at each corner of the raft. These spuds are driven hard into the bottom of the stream with a heavy wooden maul and heavy wooden wedges are driven between the spuds and their holes to make everything stable.

A windlass, securely braced, is erected at the upstream end of the craft, and about 7 ft. from the end. This 7 ft. of the upper end is used as a platform upon which to dump gravel, as it is excavated and hoisted from the bottom. The windlass has 4 in. by 6 in. standards, 3½ ft. apart, and mortised into the logs of the raft. The drum, which is 3 ft. above the water, is 2½ ft. long, 8 in. diameter, and has a crank at each end with the iron handles long enough for two men to work at each.

There is a manila rope of ¾ in. diameter, fastened to a bridle, which is in turn fastened to each side of the scoop. The scoop is about 1½ ft. wide, 2 ft. long from back to point, which is shaped like that of an ordinary hand-shovel, and 1½ ft. logs on the sides. It is about 5 in. deep, and is made of 1/8 in. steel reinforced with a 3/8 in. by 2 in. iron strap along each side. A wooden handle 14 ft. long, 4 in. by 6 in., is fastened to the scoop, near the upper end of the handle there are 1½ in. holes, 2 ft. between centres, through any one of which a round wooden stick can be fastened to use as a handle.

The method of operation is as follows: one man grasps the round wooden handle, which has

been fastened through the scoop-handle at a convenient distance, and walks back down-stream on one side of the well as one or more men reel out the rope at the windlass. When he has reached the end of the well and the scoop-handle is almost vertical, he puts his weight on the scoop by bearing on the cross-handle, and the men on the windlass slowly wind-in the rope, dragging the scoop along the bottom toward the windlass. When the scoop is thought to be full it is hoisted to the surface, swung over the platform, and dumped sideways, as the scoop-man twists the scoop-handle to the right by the wooden handle that is fastened through it. This completes a cycle of digging operations that may take two or

Crew

Thus a crew of 8 men is needed, 5 for digging, and 3 for washing, when the ground is hard; although sometimes, in easy ground, one man on the windlass, one on the scoop-handle, one on the pump, and one shoveling into the *Amerikanka* and screening, or four in all, will suffice. Women often do the pumping and washing in such hand-dredging operations in the Ural mountains.

Capacity and Cast

The capacity of an 8-man plant in loose gravel of medium size, working at a depth of about 8 ft., is from $2\frac{1}{2}$ to 5 cu. yd. per 12-hour day. Counting

PLAN AND ELEVATION OF THE HAND DREDGE.

more minutes, depending upon the difficulty of excavating and the depth.

Four men usually work on the windlass, though often in hard ground two more, who ordinarily work the washing-plant, may also help. It is hard work, and the scoop is often only moved by four or more men jerking on the windlass handles together. When the gravel is hard, a hook is substituted for the bucket to loosen the gravel previously to digging.

The washing plant consists of an *Amerikanka* mounted on another log-raft about 20 by 6 ft. and also anchored with spuds, alongside the first raft. The *Amerikanka* is supposed to have derived its origin from America, but its resemblance to American gold-saving devices is a little remote. It is more like a long-tom than anything else. It is usually about 6 ft. long, about 1 ft. wide, 6 in. deep, and it has a fall of 2 ft. in 6 ft. There is a screen-plate at the upper end, and riffles made of twigs bound together with string are laid on the bottom. No quicksilver is used. A home-made wooden pump with a 4 in. barrel furnishes water.

The gravel is shoveled from the platform upon the screen by one man, another pumps water upon it, and a third rakes it back and forth over the screen, and shovels off the oversize when cleaned.

wages at 40c. per day, as in the Urals, this gives a cost of 64c. to \$1.28 per cu. yd.; or in East Siberia, where wages are about 50c. per day, 80c. to \$1.60 per cubic yard.

Missouri leads all the other states in the production of zinc and lead, according to figures compiled by the United States Geological Survey, in co-operation with the Missouri State Geological Survey. The total value of the mineral products of the state in 1912 was \$58,332,550, an increase of \$6,399,644 over 1911. The quantity of sphalerite concentrate increased from 217,812 short tons, valued at \$8,680,550, in 1911, to 244,986 tons, valued at \$12,346,922, in 1912, and the quantity of zinc carbonate and silicate concentrate increased from 20,119 tons, valued at \$477,420, in 1911, to 22,172 tons, valued at \$641,881, in 1912. The recoverable zinc content of the ores produced in Missouri in 1912 amounted to 136,551 short tons of metals, valued at \$18,884,038, against 122,515 short tons, valued at \$13,966,710, in 1911. The output of lead concentrate decreased from 258,240 tons, valued at \$12,469,260, in 1911, to 256,838 tons, valued at \$11,948,358, in 1912. The recoverable lead content of Missouri ores in 1912 was 177,069 tons.

Mining Problems and the Mining Congress

By D. W. BRUNTON

*The difficulties under which coal mining operations are carried on and the restrictions by which that industry is hampered have been so graphically described during discussions at our meetings elsewhere that it would be a waste of time for me to repeat them. Adverse as these conditions may seem, they are no worse than those under which precious and semi-precious metal mining is carried on in the West. In order that those of you who are not personally familiar with precious metal mining may understand the difficulties under which we operate, allow me to sketch briefly the discovery and history of a Western mine.

Location of the Claim

As soon as a prospector who has been tramping over the hills, perhaps for many weary years, discovers the outcrop of an orebody, he makes a location as prescribed by law, and by the time he receives the first assay returns on the ore he has exposed not only the ground adjacent to his location, but his claim itself will be covered two or three layers deep by conflicting locations, running in every possible direction.

He then proceeds to perform the \$500 worth of work required by the government before United States patent can be obtained. When the work is completed, patent surveys made, and the advertising period ended, he finds himself face to face with a number of adverse claims, the fierceness with which these conflicting claims are fought being dependent, not so much upon the supposed rights of the people who are opposing him, as on the value of the mineral in his claim. The mine is not yet producing, he has no money to fight these adverse suits, and he must either compromise by conveying a portion of his discovery to the men who are attempting to rob him or give up an interest in his claim to some one with ready money who will finance his legal battles.

When this fight is over, if the surface openings still continue to carry ore in depth, he begins shipping, and before he has time to reap the reward of his labors, or accumulate a respectable surplus, he finds himself confronted with one or more 'apex' lawsuits. It is a most unusual thing for a mine to find its way into the producing stage without having to fight one or more 'apex' lawsuits, and all because our legislatures in 1872 gave us the most archaic law that was ever placed on the statute books. No other nation possesses such an antiquated, absurd, and irrational mining law, which, no matter what it was intended to do, has only resulted in a continued expense and annoyance to mine owners and big fees to lawyers and experts. If the possibilities of litigation ended with the first few years of exploration, the case would not be so serious, but some of the most bitterly fought and expensive lawsuits have arisen between claims which have been in operation for many years. At the present time two of the

greatest mines in Cripple Creek, which have worked together in peace and harmony for over fourteen years, are fighting a two and one-half million dollar battle, all because of the discovery in one of the workings of a spur or branch of the main orebody. One of the most disastrous effects of this continuous litigation is to frighten capitalists away from mining investments, because observing Eastern investors have learned that the discovery of a new mine carrying rich ore is almost certain to be the beginning of the most expensive and interminable litigation.

Some years ago the United States government appointed a committee to examine and report on the advisability of revising our present mining laws. Some of the ablest men in the industry were placed upon this board and, while their report was pigeon-holed and never made public, I understand it was unequivocally in favor of a complete revision. The Mining and Metallurgical Society, the American Institute of Mining Engineers, and the American Mining Congress each have had committees composed of representative mining men from all portions of the United States investigating the desirability of a change in our mining laws, and the reports of the committees appointed by all of these societies have been unanimously in favor of an entirely new code, as piecemeal revision seems not only undesirable, but under present conditions, almost out of the question. The American Mining Congress is joining hands with the American Institute of Mining Engineers and the Mining and Metallurgical Society, and together we hope to arouse public opinion to the necessity of making a complete revision of our present mining law. Neither revision nor repeal will, however, be an easy task, as the apex side-line features of our mining law have proved a veritable mint for lawyers and experts.

Smelting the Ores

Let us follow our typical mine a little further. If the composition of its ores is such that they can be treated by themselves at or near the mine the owner may congratulate himself, but, unfortunately, the great majority of our precious or semi-precious metal mines carry ores which contain several metals, usually associated with sulphur in such a form that they can be most successfully treated by smelting. This is an operation which experience has shown requires a wide mixture of ore to avoid the necessity of using dead fluxes; consequently, the ores have to be shipped and sold to a smelting company, situated, usually, at some convenient railroad centre. Years ago there was ample competition among the numerous smelting companies, and the miner could be sure of obtaining all that his ore was worth under existing conditions. Today most of the plants have passed into the hands of a few great corporations, which practically amount to a gigantic monopoly, which not only tells the miner flat-footed what they will pay for his ores, but in some instances, just how much they will permit him to produce. It would

*Abstract of Presidential Address, delivered before the American Mining Congress at Philadelphia, October 20.

seem that all these things are about as great a burden as an industry could bear, but our typical miner has still more troubles.

The Forest Service is doing splendid work in the preservation of our forests, but the organization is still young and somewhat imperfect; many of the superintendents and rangers are not only untrained, but are overzealous and officious, and as a consequence rules and restrictions, made with the best intentions in the world, are often misinterpreted and the mine owner sometimes finds it difficult to obtain timber for mine supports and fuel, permission to build roads, or to lay pipe lines, without carrying on an interminable correspondence and waiting until reels of red tape have been unwound. In addition to this the Government has now stepped in and withdrawn coal lands and water-power sites from entry. The operations of hoisting, pumping, air-compressing, and ventilating all require large amounts of power. Picture to yourself the feelings of a mine owner with an undeveloped coalfield or an unused water-power near his property and yet, to all intents and purposes, as far away as if situated in the mountains of the moon.

The Tax Burden

The drawbacks already enumerated, which seem to be sufficient to discourage any industry, are bad enough, but the end is not yet. The soil in the valleys of our Western mountains is extremely rich, the mines furnish a near at hand and high priced market for all the products of the range, field, and garden, consequently tillable land anywhere near the mines is rapidly taken up by settlers, and, so generally successful are their operations, in a few years the agricultural population is sure to outnumber the miners, a condition which already obtains in nearly every mining state in the West. Just as soon as a farming community gains numerical strength sufficient to make itself felt in legislative halls, its first act is to place the principal burden of taxation upon the mines. There is scarcely an exception to this anywhere in the West. For instance: In Colorado the mines are now assessed at their entire cash value plus one-half of the annual gross output, plus the total net output, while the agricultural and fruit lands of the state are, in many cases, only assessed at one-third to one-fifth of their actual market value. In Arizona a law has recently been passed under which the mines are assessed at their full cash value plus one-eighth of their annual gross output, plus four times their net output. Nothing could be more ruinous or unfair to the mining industry, yet, it is difficult to see how it is possible for the mine operators to prevent or repeal such iniquitous legislation with a minority vote.

Nor are they content with this. In many places the farmers have not only attempted but succeeded in throttling the very industry which called them into existence and made them prosperous. In Montana, Utah, and California the agriculturists have actually succeeded, by means of legal injunctions, in closing up or obtaining unheard-of damages from these smelters on account of alleged damages to crops, which any impartial observer knows are often entirely mythical. In fact 'smoke farming' has be-

come a recognized business, and lands in many localities near a smelter are now worth much more than they could have been sold for before 'smoke suits' were instituted. The Amalgamated Copper Co. has already paid out more money for damages, alleged and real, to the lands of farmers around Anaconda than the entire valley could be sold for if the smelter were not in existence. This, in spite of the fact that the Company maintains near the smelter an experimental farm which raises the largest crops and the finest cattle in the state. In California the farmers have made placer mining difficult, and in many places impossible. These things may seem incredible, but they are absolute facts, as everyone conversant with present conditions in the West is fully aware.

The necessary risks and difficulties attendant upon mining operations are a sufficient load for any industry to carry, but there are many things other than those already mentioned which the Mining Congress hopes to be able to change. For instance, an experienced miner, for the love of change or from being dissatisfied with his condition in one state, moves to another where a different code of signals is employed. He is, of course, careful to study the new code, but some day before the use of the new signals has become entirely mechanical he absently gives a wrong signal and the unlooked-for result is often disastrous. Again, a miner who has been working in a mine with an electrical equipment for power and lighting of 220 volts, changes to another property, perhaps in the same district. Two hundred and twenty volts, as we all know, is comparatively harmless, but in the new mine where our miner goes to work, the potential on the underground line is 440, or perhaps even 2200, and, without realizing the difference, he is as careless in handling or working about the high potential line as he formerly was with the low, and the results are unexpected and perhaps fatal. This illustrates emphatically the necessity for a uniform system of electrical equipment throughout the entire country, and committees from the Mining Congress and engineering societies have already drafted rules and regulations for uniform and safe underground equipment which should become a law in every mining state.

Mine Accidents

In any mine, no matter how stringent rules may be adopted for the protection of the miners and the prevention of accidents, careless workmen will sometimes drill into missed shots, postpone timbering weak ground, ride on loaded cars, or walk into open winzes or shafts. Accidents from these sources occur with altogether too much frequency and, while they are something which the operator has taken every precaution to avoid, they are and must remain a burden on the industry. At the present time in most states when an accident of this kind occurs, the contingent fee attorney is immediately on hand and a prolonged period of bitter litigation ensues, and when a verdict is finally reached the crippled workman or his family gets practically nothing; court costs and lawyers' fees having absorbed nearly, if not all, of the award. To obviate this, a number of states have recently passed what are known as Em-

employers' Liability or Workmen's Compensation laws, and so far as I am able to learn, in every state in which such laws have been passed the results have been extremely gratifying. The cost to the employer has been no greater than before, while the sufferers get from two to ten times as much as they did under the antiquated laws in force in most states, and, what is even of more importance, they obtain the compensation immediately, instead of at the end of an exhaustive and embittered struggle. For this reason the American Mining Congress urges the passage of laws of this kind in every mining state, because it is certain the result will be a direct benefit to both employers and workmen, besides tending to bring about a much better feeling between these two representative classes.

A Law to Regulate Pumping

When our typical mine finally reaches a stage where deep explorations are necessary, water is generally encountered, sometimes in sufficient quantities to make pumping a most serious item of expense. So long as pumps only drain the property in which they are situated, all goes well, but it often happens that, owing to the presence of numerous cracks and fissures, or the permeability of the rock itself, it is impossible to drain one mine without lowering the water-level in the mines immediately adjacent. This throws a most unjust burden on the pioneer company, for which at present it has no recourse, and it has either to stand the expense of draining all the surrounding territory or cut down its rate of development to the average of the mines about it. We need a drainage district law which will compel every one operating mines within a given district to bear their proper share of the expense of pumping.

As soon as the earliest developed mines in a new district begin shipping any considerable amount of valuable ore, a parasitic population descends like a cloud on the camp. Prominent among this class is the mine promoter, the better class among whom carry on a perfectly legitimate and useful work, as they raise capital with which to develop new mines or promising prospects; but obtaining a bond or purchasing a promising new mine or prospect costs real money, consequently the impecunious and irresponsible brokers usually pick up worthless claims which can be had for little or nothing, and then proceed to boom them by means of flamboyant prospectuses and magazine and newspaper advertising all over the United States. In the district it is easy to distinguish the difference between a valuable property and a worthless one, but a thousand or two miles away it is exceedingly difficult to discern the difference between their prospectuses. In fact, as a general rule, the wild-cat promotion is groomed until it presents a more attractive appearance on paper than the genuine article, and as a consequence the country is annually flooded with millions of dollars' worth of absolutely useless mining stock, the effect of which is to absolutely discredit mining operations of all kinds in the minds of the unfortunate purchasers. The Mining Congress has for years urged the passage of laws which would make wild-cat promotions impossible, legisla-

tion which should be of the greatest benefit both to Eastern investors and to the mining industry. Kansas and California have already passed laws of this kind, and we hope that the other mining states will soon follow in their footsteps.

The greatest service the Mining Congress has so far been able to perform for the benefit of the mining industry has been the assistance it was able to give in the creation of the Bureau of Mines, which we hope and confidently expect will do as much, and even more, for the mining industry as the Department of Agriculture has been able to do for the farmer. It took years of patient endeavor to arouse sufficient interest in the matter and to build up public opinion to a point where our national Congress appreciated the necessity of giving such an aid to mining, and, although the Bureau of Mines was not organized until 1910, the magnificent results which it has already accomplished have more than convinced every one of its value. The experiments and work which it has carried on at the Pittsburgh testing station on explosives and explosions have marked a new epoch in scientific investigations on the causes of explosions and the properties of explosives, the practical results of which have been a steady annual decrease in the number of coal-mining accidents. Even here, however, there is still much to be accomplished, as there is no reason why mining accidents, both serious and fatal, should be two and a half times as great in the United States as in Great Britain.

Work of the Bureau of Mines

Until this year the work of the Bureau of Mines has been almost entirely confined to coal-mining in the East, but the last Congress gave an appropriation of \$100,000 for Western metal mining. This appropriation only sufficed for the opening of chemical and microscopical laboratories, which have been established in Denver and are already carrying on a most valuable and useful work in the investigation of the properties of the rarer metals and in petrographic and microscopic studies of our low-grade complex ores. Investigations are also being conducted at the present time on concentration methods and the adaptability of the various methods now in use to the different ores found throughout the Rocky Mountain region. The Mining Congress hopes soon to see a large testing station, something on the lines of the one now in use at Pittsburgh, established somewhere in the West, where experimental work on a larger scale than is possible in a laboratory could be conducted. The able and enterprising Director of the Bureau of Mines is extremely anxious to make this installation, and the Mining Congress expects that every one connected with the industry will do what he can to assist the Bureau in obtaining a sufficient appropriation for this work.

The total appropriation this year for the Bureau of Mines was only \$662,000, a very considerable part of which was spent in testing coal purchased for the Navy, the Panama canal, and other necessary government work. Compared with the appropriations made for the Department of Agriculture, this sum is hardly worth considering, and, when we stop

to realize that the products of the mines are equally as essential to the wealth and welfare of the nation as those of the farms, it is evident that larger appropriations for the support of the Bureau of Mines are not only desirable, but absolutely necessary. A power-plant, no matter how perfect its design or excellent its workmanship, is absolutely useless without an adequate supply of fuel, and unless the Bureau of Mines is given ample funds for the work ahead of it, the results attained will fall far short of our expectations and necessities.

The speeches and debates that you have already listened to give some idea of the requirements of the coal-mining industry, while the examples I have just cited in the history of a typical precious-metal mine give some, although not all, of the defects in our present system for which some legal remedy is required. We all know that mines can neither be called into existence nor made profitable by legislation, but we do expect that laws will be framed and passed which will afford equal opportunity to all and just protection to every one who risks either life or capital in the industry. The motto of the Mining Congress is safety and efficiency, by which we mean not only security to the investors and owners, but health and safety to our employees as well. The American Mining Congress is the only organization covering the entire United States whose sole business it is to look after the legal and commercial interests of the coal and metal mining industries, and the work which it entails necessitates a continually increasing expenditure of time and energy. There is nothing so effective in carrying out legislative reforms as a thoroughly aroused and insistent public opinion, a condition which in this case can only be reached by a continuous and well conducted educational campaign. To conduct this effectively we require more funds and a greatly increased membership, and we hope that every person directly or indirectly interested in mining will see that it is to his best interest to become a member of the American Mining Congress. This would give us immediately a vast increase in both funds and influence, without which no great improvement in present conditions can be expected.

The results of experiments conducted in connection with the treatment of tin and zinc ores in an electric furnace in England and France have been satisfactory enough to open up many possibilities for electric smelting. In France the tests were carried out on a new process, and a project is on foot to establish it in conjunction with a hydro-electric scheme, which it is hoped will restore the zinc mines in the vicinity of the Pyrenees to their former activity. The tests on the reduction of tin ore in the electric furnace were extensive, and were conducted by the Gröndal-Kjellin Co. of London in Cornwall. The results were favorable, pure ores yielding metal of 98% purity, while Bolivian ores containing 49.5% of tin and about 15% of iron yielded metal of 92 to 97% purity, which could be further refined to 99.75% or more by blowing air through the molten mass. The energy consumed amounted to 1700 kw-hr. per ton on the average. By working with two furnaces, one to treat the

rich slag and the other to produce the metal, the company hopes to reduce this consumption to 1400 kw-hr., giving an efficiency of 55%. There is a saving of 25% of labor.

The Calumet Dredge

The Calumet & Hecla M. Co. has recently built a dredge for reclaiming the tailing from Torch lake, and for the following details of construction we are indebted to James MacNaughton, general manager.

The dredge is designed to excavate to a maximum depth of 100 ft. below water line. The hull is of steel, 72 ft. wide by 110 ft. long, and weighs approximately 450 tons. The machinery, exclusive of motors, weighs approximately 300 tons. The material to be dredged consists of stamp sand all finer than $\frac{1}{4}$ in., in two piles of approximately 20,000,000 tons each in Torch lake, the centres of piles being approximately 2000 ft. apart.

The dredge is to be equipped with two 20-in. centrifugal pumps so arranged that material discharged by No. 1 pump passes through a trommel to a sump connected with the suction of No. 2 pump, which delivers it through a maximum of 2400 ft. pipe. Suction piping is so arranged that either pump can be run alone for pumping material ashore by cutting out the trommel. The material rejected by the trommel is delivered to a scow alongside of the dredge by a chute. To hold the dredge to its work six swing lines and one stern line are provided.

The dredge pumps are 20 inches in diameter, with 54-in. runners. The pump casings are not lined. Flexible couplings connect pumps to 2300-volt induction motors, one pump having a 600-hp. and the other a 1000-hp. motor.

The ladder for supporting the outboard suction pipe consists of latticed steel girders, pivoted to the hull and braced sideways with wire rope. The pipe is lap welded, 21 in. outside diameter, and connected to pumps by cast steel swivel joints. The lower end of outboard suction pipe terminates in a suction head, provided with annular water chamber and nozzles for loosening material. No cutter head is used. The lower end of the suction pipe also has means for admitting water from above in case of the clogging of the suction mouth by its being buried in the sand. The suction ladder is hoisted by wire ropes operated from an electric winch.

The No. 1 pump will discharge into a hopper feeding a trommel 7 ft. in diameter by 45 ft. long provided with screens of manganese steel with 1-in. openings. The oversize consists of accumulated rubbish, which is discharged into a scow, the undersize discharging into a sump in the hull from which it is picked up by No. 2 pump and delivered to a fixed point on shore.

The dredge is provided with all the necessary auxiliaries, including winches, compressor, jet pump, bilge and priming pumps, steam boiler for heating purposes, crane, etc. The hull and dredging machinery were furnished by the Bucyrus Co., with the General Electric Co. furnishing electric equipment. Electricity is generated in the stamp-mill powerhouse, and wires are carried to the dredge on discharge pipe pontoons.

Cooperation and Formation Names

Mining engineers and geologists who have been confused by the rapid invention of geologic formation names, will approve of an effort that is being made in the Mississippi valley states to coöperate in future studies of the Mississippian formations. A significant field conference was held, as already noted, October 10-12 in Missouri for the purpose of planning joint studies by the several states and the United States Geological Survey. The states represented were as follows: Arkansas, Purdue; Illinois, DeWolf; Indiana, Barrett, Beede; Iowa, Kay; Missouri, Buehler, Hughes; Ohio, Prosser; Oklahoma, Ohern, Snider; Tennessee, Purdue. The U. S. Geological Survey was represented by David White, chief geologist, and W. H. Herron, geographer in charge of the central section.

The discussion showed clearly the evils of work in adjoining states without due consideration of that already done or in progress in adjacent territory. Since considerable new work is now being done on the Mississippian formation, it is highly important that the new stratigraphic units and formation names which may be proposed shall be carefully considered in the light of past usage and general rather than local needs. A directing committee, consisting of H. A. Buehler of Missouri, G. F. Kay of Iowa, and A. H. Purdue of Tennessee, was authorized to confer with the chief geologist of the U. S. Geological Survey and to begin active direction of coöperative work. It is probable that field work will continue to be done by the several states, although the U. S. Geological Survey will contribute to this phase of the work and will probably assume the responsibility for publishing the monographs as they are made ready from time to time.

In connection with the conference the party examined an interesting section in St. Genevieve county, Missouri, in which all of the formations from the Cambrian to the top of the Mississippian are exposed within easy reach. The conference continued for three days, and was not only exceptionally enjoyable, but promises to pave the way for interstate coöperation in all future problems which have general significance.

Mineral Production of Michigan

Michigan is sixth among the states of the Union in the value of its mineral production, according to the figures compiled by E. W. Parker, of the United States Geological Survey, in coöperation with the Michigan State Survey, it ranked second, and in the production of copper it was third. Among the less important branches of the mining industry it ranks first in the production of salt, bromine, calcium chloride, graphite, and sand-lime brick, second in the production of grindstones, and fourth in the production of gypsum. In 1910, the total value of the production considered, the mining of iron ore was the leading industry in Michigan, but in 1911 and 1912 the value of the recoverable metallic content of the copper ores produced in Michigan exceeded the value of the iron ore mined. In 1912

the production of iron ore amounted to 12,797,468 long tons, valued at \$29,003,163, and the copper production to 218,138,408 lb., valued at \$35,992,837. The total mine production of copper in the United States in 1912 was 1,249,094,891 lb., of which Michigan contributed 218,138,408 lb., or 17 per cent.

The total production of copper in Michigan from earliest records has been about 5,200,000,000 lb., or about 30% of the total output of the United States.

Michigan stands well up among the states in the manufacture of cement, producing 3,494,621 bbl. in 1912. The salt production of the state (exclusive of rock salt) amounted to 10,271,715 bbl., valued at \$2,743,389. The value of Michigan's clay products increased about 22%, from \$2,083,932 in 1911 to \$2,545,498 in 1912. The mining and calcining of gypsum is also an industry of considerable importance, and production increased from 347,296 short tons, valued at \$573,926, in 1911, to 384,297 short tons, valued at \$621,547, in 1912. The total value of the mineral products in Michigan in 1912 was \$80,062,486, against \$65,275,324 in 1911.

The Innoko-Iditarod Placers

During the summer of 1912 Henry M. Eakin, of the U. S. Geological Survey, visited the Ruby, Innoko, and Iditarod districts in Alaska, and a report on the gold placers in those districts has been issued by the Survey. The mining centre of the Ruby district is about 25 miles south of Yukon river at Ruby and comprises half a dozen creeks, all within an area of a few miles square. The first discovery of gold in this district was probably that made on Ruby creek in 1907, near the site of the present town. This discovery proved to be of no great importance, and it was not until 1910 that the discoveries on Long creek and its tributaries created widespread interest in the region. Exact data regarding the amount of gold produced in the district are not available, but the total in 1912 was probably between \$150,000 and \$175,000.

The Innoko-Iditarod region lies in west-central Alaska and embraces most of the upland area north of Kuskokwim river that is drained by Innoko and Iditarod rivers. In all, 24 claims, located on five creeks, were worked in the Innoko district in 1912, by a total force of about 140 men. The total value of the placer gold produced during the year in the district was probably in excess of \$250,000. Twenty-nine claims, located on eight different creeks, were worked in the Iditarod district in 1912. Thirty-six plants were engaged in the work, and about 975 men were employed. The value of the total gold production of the district, including Moore creek, for the year was probably about \$2,750,000.

Coal is mined in New Zealand by the government at two collieries, which produced a total of 247,200 tons in 1912. This is partly used by all the state departments and the balance is sold to the public. After deducting depreciation at the mines and coal depots, there was a loss of \$48,000 on the year's work.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Simple Smelting

The Editor:

Sir—The letter published in the *Mining and Scientific Press*, September 27, under the caption, 'Simple Smelting in Arizona,' reminds me of an incident that occurred in Nevada City, California, in 1851, an account of which is given in E. F. Bean's 'History of Nevada County,' published in 1867. I have not a copy of the history at present, but the article below will be found to be largely word for word with the account of Mr. Bean's. One Dr. Rogers, becoming possessed by the idea that heat would free the gold from rock, proceeded to talk the idea into others. He finally raised the money from some of Nevada's wealthy citizens to make the experiment. He built a furnace in which to heat the rock, under which there was placed a large iron tank for the purpose of catching the precious metal as it fell from the furnace. The furnace was filled with alternate layers of gold-bearing rock and fuel. The fire was lighted at the bottom and as the mass lowered more rock and fuel was added at the top. The millionaires who were financing the project were on hand night and day in anticipation of a princely haul, the 'savant' who was testing his discovery on a large scale at a snug salary, rode up occasionally and gave his orders, which his employees obeyed. After tons upon tons of milk-white rock had passed into the furnace, when the vulgar crowd, who had no soul for science or pluck for advanced enterprise had departed, the first and only clean-up was made. A stout armed person made his way to the tank where the precious metal was supposed to collect.

He scraped the bottom and returned with a pan of cinders and ashes, the bubble had burst, and so had some of the millionaires. Dr. Rogers left the camp declaring that quartz mining was a humbug and he would leave it to its fate.

R. NOBLETT.

Nevada City, California, September 28.

The Extralateral Right

The Editor:

Sir—If, as is recommended by Messrs. Winehell, Goodale, and Requa in their report, the extralateral right law is repealed, as it ought to be, the present requirement that the side-lines of the claim shall be laid off at equal distances from the outcrop of the vein should also be repealed. The law should allow the prospector to locate the side-lines at unequal distances from the apex of the vein if he so chooses. In the case of inclined veins of low dip, obviously, if one side-line is placed just outside the apex, the vertical planes passing through the side-lines will enclose on the dip nearly twice as much of the vein as would be enclosed if the side-lines were at equal distances from the apex, and this would only be fair to the surface discoverer.

Years ago an old-time prospector, a veritable crusader in favor of the extralateral right, related to me the following incident. He said: I was in Nevada when prospectors and miners made the rule that every man should have the right to follow his vein down, no matter where it goes. This resulted in a great mass meeting. Most of the speakers wanted to have the claims bounded by vertical planes. At last an old prospector stood up and said: "Maybe you fellows want to cut yourselves off from the bottom of your vein, but as for me, I want to follow mine." The debate was decided in favor of the prospector.

Doubtless this brief speech sums up the only argument that ever has been made for the extralateral right. It will go a long way toward reconciling the friends of that right, if it is repealed, to permit the locator of a lode claim to place the side lines at unequal distances from the outcrop of his vein if he so prefers. This would give him a good mine if the vein is of value and suitably favors the surface discoverer.

Colorado Springs, Colorado, October 18.

Government Prospecting

The Editor:

Sir—Having recently read the articles of Albert Burch and R. P. McLaughlin in regard to government prospecting, I would add that it appears very doubtful if government prospecting can be done successfully, as the cost would be excessive, judging by the bureaucratic methods and 'red tape' of government officials in other lines. The poor prospector would be worse off than under the present arbitrary rulings of the land office and the regulations of the Forestry Department as construed by some of the forestry agents.

Mr. McLaughlin's proposal that companies be induced to try it might work out advantageously; but judging from all past experiences, it will not be possible to interest them. All of our largest mining companies, and individual operators, spend thousands of dollars every year in the examination of developed and partly developed mines, but they cannot be induced to look at a prospect. Several of the large operating companies in recent years have examined 600 or more reports on mines each year, and their engineers have been sent to make examinations of those which were most attractive. In no case have they taken over more than one-half of one per cent of those presented. If ten per cent of the money thus expended was used in assisting or paying a few good men to prospect, I believe more would be accomplished.

Mr. McLaughlin's definition of the prospector, "an ordinary man with some knowledge of minerals and possessed with the spirit of adventure," probably applied to the average prospector of the past. I think at the present the chances of success are far more favorable to a better class man, especially one familiar with the rarer minerals and possessing some knowledge of the geology of ore deposits. The days of the prospector looking for certain classes and conditions of formation are past. The field of pros-

pecting for the rarer metals, blind veins, and dry placers is still large. Only the quartz veins exposed above the surface, generally speaking, have been found. I know of four tungsten veins accidentally discovered in this county during the past year.

Reno Sales, in his excellent article in a recent bulletin of the American Institute regarding the Butte ores, says that nearly all of the copper veins of Butte were blind veins and rarely showed more than a trace of copper at or near the surface. Some of the best deposits of copper at Cananea were only barren quartz veins at the surface.

If government assistance is desired, why not adopt the Australian plan? The government there, I understand, gives a bonus premium to anyone who discovers a producing mine. Districts where water and transportation are difficult and expensive, the Australian government does this work, pipes in the water, and makes good wagon-roads or railroads, as needed.

Everyone will recall old camps in the United States today that could and would be rejuvenated if they had better and cheaper transportation. This certainly is as legitimate a field for government work as to make roads for the agriculturist. In many instances it would benefit both the miners and the ranchers.

I would recommend that the present mining laws be changed or altered to conform more with present conditions, insisting that they be liberal to the prospector and the man who actually does the first development work.

Let there be a justifiable appeal from the decisions of the land office. Cancel one-half of the present forestry reserves, especially all in the arid belt, where there never was an excuse for a reserve. Confine the forestry service agents to fire protection of present forests and the reforestation of districts where trees can be made to grow. If this is done, I venture the prediction that there will soon be plenty of prospectors in the hills.

G. L. SHELDON.

Ely, Nevada, October 6.

Professional Ethics

The Editor:

Sir—Mr. Caetani's citation of a contingency which may occur in the career of a mining engineer, given in your issue of September 13, seems to me to resolve into a question of honesty to self and to clients 'A' and 'B'. Hair-splitting technicalities and ethical doubts should give way before common sense; and if this is done, the engineer will know what to do.

Professional ethics decree that he shall not give to 'B' the report made for 'A', because he was detained by client 'A' to examine the mine and submit the report. When client 'B' retains him for the purpose of examining the same mine and submitting a report, the engineer is not morally or professionally obligated to refuse the business just because he shortly before had reported upon the same mine for 'A'. Yet he would have to decline unless he used the information gained while in the service of 'A', which, ethically, he should not use. If 'A' refuses to give 'B' the report, or refuses to

sell it, then, ethically, the engineer would have to make another examination and submit another report to justify his services to 'B'. But this would be running a bluff on the engineer's conscience and client 'B', because the conditions at the mine have not materially changed since the examination for 'A'.

This matter should be settled by sweeping aside technicalities and doubts. A statement of the plain facts should be made to client 'B'; let him understand that an examination, except perhaps the question of sampling, would be practically a repetition of the former work; that the previous examination was made at the request of client 'A' (this is discretionary); and that the report to him ('B') is taken largely from the other report. The statement of facts should also be presented to 'A'.

By doing this the engineer would be honest with himself and with his clients, ethies or no ethies. He is entitled to 'B's business and should give 'B' his report.

J. M. LILLIGREN.

Pearl, Idaho, September 19.

Trent Agitators

The Editor:

Sir—Your issue of September 6 contains a communication from Walter E. Techow which emphasizes the fact that the Trent agitator is easily started after a shut-down of a number of hours. The point of interest lies in the statement that as the ore is clayey and pulp is 1.25 to 1.35 sp. gr., he "does not know of any other agitator that would do the same thing under parallel circumstances."

After the wave of reaction against the Pachuca tank, which has been dubbed by many distinguished metallurgical essayists, "a metallurgical fad that would run its course," it is of interest to note that, under very similar circumstances, the Pachuca tank has exceeded the length of time mentioned in Mr. Techow's instance, with no bad results.

I refer to the battery of Pachuca agitators at El Tigre, Sonora, Mexico, during the siege and capture of that camp in September 1912 by Inez Salazar and his band of 'red flaggers.' These particular tanks are 40 ft. high, with average depth of pulp 38 to 39 ft., and the pulp, like Mr. Techow's, is clayey and varies between 2.2 and 2.6 to 1.0 in ratio of liquid to solid.

On September 13, 1912, the camp was attacked at 6:30 a.m., but the air-compressors ran till about noon that day. From that time on the agitators were 'dead' and the mill was idle until 7 p.m. September 17, at which time the camp was recaptured and work resumed. On returning to the plant, it was noticed that clear solution had gathered on the surface of the charge to such a depth that the pulp, proper, could not be seen. Nevertheless, all the tanks were put into commission once more without the aid of anything save the regular air-pipe equipment of the tank itself, and inside an hour all eight were agitating as freely as usual.

The pulp yields about 80 to 85% of -200 mesh material, and was of that nature during the episode referred to above. Disregarding other points of comparison, one can well believe that the Pachuca

need not accept odds on this score from any other agitating device now in use.

DONALD F. IRVIN.

Yzabal, Sonora, September 9.

[It is but fair to Mr. Techow to state that his original letter was not intended for publication and was printed through a mistake on our part. It has, however, served a useful purpose in calling out this discussion by Mr. Irvin, and Mr. Techow has kindly pardoned our mistake.—EDITOR.]

Some More Reasons Why Mining Languishes

The Editor:

Sir—I would like to throw into the mortar of correspondence a few old random samples for the various 'fans' of mining to pulp up and pan out. In the first place, it is right to concede all diversity of opinion as the case fits the many authors or correspondents especially on these lines. It is an established and undisputable fact, that, with a few exceptions, from the professional mining engineer to the pseudo-pro prospector, all are trying to make money easily, and here I would emphasize the fact that within the borders of the United States the day has long ago vanished when it was possible to find great bonanzas lying on the surface or projecting above ground. The almost universal knowledge of ores and the ready access to assay offices has in the past 15 years pretty thoroughly covered every mining district and much other territory; and henceforth mines will require more work and time before they are on a paying basis than in the past. The traditional get-rich-quick idea in mining must be eliminated. There is a new lesson for the mining engineer to learn, that is, to recognize and to know a prospect that will make a mine from one that will not. I fail to see any ability, credit, or honor for the mining engineer or geologist who has to have the property developed by a shaft 500 ft. deep and a level 500 ft. each way from the shaft at every 100 ft. before he can form an idea of its value. In reality he is not needed, it is simply a matter of careful sampling and ordinary arithmetic, and while telling how it happens that the ore really is there, is of some satisfaction, it is of no value from a dollars and cents standpoint. It is perfectly correct to go out prospecting among the prospectors, but it is wrong to imagine that anyone is going to find a prospector with a bonanza and brains of too poor a quality to convert the ore into money, or who does not know a good thing when he has it. However, the prospector is generally a poor man, and when there is anything in sight it always evolves itself into a long bond and easy terms, which shows that the buyer has no confidence in the property, and the result is that sales are few. If your judgment is unreliable, hire some one who is possessed of it, or quit the business. Experience has taught me that bonding mines and prospects is an expensive luxury, and I quit it years ago. Now when I look at a prospect or a mine, I take with me three articles, a hand pick, some sample sacks, and a check book. Here let me cite a few striking illustrations, namely: three men owned a group of three slightly developed claims which I examined and found satisfactory. I asked them for their lowest price and best terms,

and was told \$15,000; \$5000 down, balance in six months and one year. I told them I would be at a certain place until 10 o'clock the next day, and if they wanted \$2500 cash to come and see me, with the result that I bought the property. In another case a man had just located a beautiful vein having a heavy iron cap from 3½ to 6 ft. wide and continuous for over 2000 ft. in length. I asked him what he would take for his find; his answer was, "Not a cent less than \$1000." I told him I would give him \$50, and in 10 minutes the prospect was mine. Another property, which includes 158 acres of patented land, with a bond price of \$10,000, I bought for \$1150. It is not only impossible for every prospect to make a mine, but it is a good thing that such is the case. As it is, there are many good properties that can be had at a very reasonable price for cash, and in doing business on a cash basis the actual capital required is greatly reduced, and people feel more secure in their investment or speculation if you choose to call it such.

A few words on mine reports. All mine reports that I have ever made have always been divided by 2, 4, and even 6. All the reports that have in one way or another come under my observation have received the same treatment. Therefore, I believe a personal investigation is the most satisfactory, whether it is reliable or not.

Modesto, California, October 16. J. D. VOSE.

Securing Capital for Mines and Prospects

The Editor:

Sir—A great number of articles have been published during the past few years bearing directly and indirectly upon this subject. The owners of prospects and partly developed mines complain that it is almost impossible to interest capital in the development or purchase of their property, and, on the other hand, representatives of mining capital complain of the lack of good prospects or mines to buy. In a general way, there are good grounds for both these complaints.

The kind of a property that large capital is looking for is becoming scarcer every year. First, for the reason that the available area of new country, in which mines are likely to be found by prospecting, is very limited. When Colorado was new, when Nevada was new, in fact when the whole Western part of America was new, the field was large. There were more mines than money. The supply was large and many prospects were being worked, some of which, in due course of time, developed into mines. Second, experienced mining capital, which at the present time is largely concentrated, takes few chances and bothers but little with prospects which are but slightly developed. Prospects, as a general rule, are developed by the owners themselves or by a small aggregation of capital secured by the owners from their friends, usually people of limited means and following other lines of business, or by incorporating a company and selling treasury stock. In 'boom' days and under the stimulating effects of a mining excitement, the two latter methods were used frequently with great success, in so far as the raising of money was concerned. Advan-

tage has often been taken of this condition of affairs by the unscrupulous promoter to foist 'wild-cats,' with absolutely no chance whatever of developing into a mine, upon the investing public. A few flotations of this character soon destroys confidence and the good suffer with the bad. In a very short time it becomes impossible to secure money for the developing of a meritorious prospect which has excellent chances for making a mine. This is one of the conditions prevalent at the present time, and as a result the people who have had spare money to invest in mining have sought other avenues for their surplus. As I have stated before, within the past few years most of this surplus, and some that was not surplus, has gone into the purchase price and the operation of automobiles, and one does not have to go far into the statistics of the automobile trade to learn how this money has been absorbed and that its effect is felt not only in the development of prospects but in the stock markets of New York and San Francisco. A sum which approximates \$1,000,000,000 entered Detroit alone the past year for the purchase of automobiles. The purchase of accessories and the operation of these cars consumes another \$500,000,000. With the spending of these sums in a comparatively new industry, is it any wonder that there is no money for the luxury of developing a prospect? This capital, some of which at least was formerly used for this purpose and for the buying of stocks, is gone, as far as mining is concerned. Like the Missouri river after a flood, it has changed channels and left the prospect, stock market, and various other industries stranded on the dry bank. From present indications it will be a long time returning, if ever.

It is on this money, and not on the large aggregations of experienced mining capital, that the prospectors have relied in the past for the development of their ground, and its withdrawal has caused a cessation of activities. Without a prospect, it is impossible to have a partly developed or fully developed mine, and this is about the only kind of a property this experienced mining capital is looking for. Of course, they are scarce, and are becoming scarcer every year until the men controlling this capital will finally have to come to the prospecting. There are any number of fair-looking prospects in the country that need but the expenditure of a few thousand dollars to determine whether they will be mines or not. Starting with a good judicious selection, one out of ten at least ought to make good, and I believe if more attention was paid to this class of property it would not be long before there would be plenty of new mines.

This inability to secure capital for the developing of mere prospects, together with a condition discussed by Albert Burch in his article in the *Mining and Scientific Press* of August 30, that the "chances for success in prospecting have been steadily diminishing for years" has caused a withdrawal of prospectors from the field. However, I do not believe that the solution of the question will be found in government aid. I rather believe it will be found in the interesting of mining capital in the developing of meritorious prospects where surface conditions are favorable.

The company and controlling owners, by whom Mr. Burch is employed, and in fact most of the larger mining companies in Nevada, have been very much better in this regard than other companies who control capital. They have been rewarded by the successful development of several prospects during the past few years. I have no doubt that when the others realize the necessity of pursuing this course in the obtaining of mines, they will finally come to it. One successful dividend-paying mine obtained in this way pays for quite a number of unsuccessful prospects, where the expenditure of a few thousand dollars determines their value.

H. C. CUTLER.

Reno, Nevada, October 27.

Inclined Baffles

The Editor:

Sir—Your correspondent, L. B. Eames, in his letter printed September 27, is quite right in his belief that, mechanically considered, the ability of a particle to settle in a cloudy solution is limited only by its infinitesimally small weight and by the viscosity of the settling medium, but he is thinking of unhindered settlement, and this is not a condition in which the use of baffles is of assistance.

The principal retardation to settlement is to be found associated with, although not strictly due to, the increase in density brought about by the accumulation of particles in process of settlement, but the cause is not alone mechanical; one particle cannot be considered as falling through a medium of which its brethren are component parts.

The baffle is found useful in settlement from fairly thick pulps, but while it is a mechanical device, it is used to alleviate conditions other than mechanical under which the retardation is set up, and to promote free settlement; it is, in effect, another means for withdrawing the bottom layer and letting down the others, about which I have previously had something to say.

H. G. NICHOLS.

London, October 13.

Mineral Production of New Mexico

In 1912, according to the U. S. Geological Survey, owing to a marked increase in production, the value of the recoverable copper content of the ores mined in New Mexico exceeded the value of the coal mined. The increase in the copper production was due principally to the operations of one company mining with steam-shovels a large acreage of low-grade deposits at Santa Rita. In 1911 the recoverable copper content of the ores mined in New Mexico was 4,057,040 lb., valued at \$507,130; in 1912 this product amounted to 34,030,964 lb., valued at \$5,615,109, the quantity in 1912 being approximately 8½ times and the value more than 11 times that of 1911. The coal production increased from 3,148,158 short tons, valued at \$4,525,925, to 3,536,824 short tons, valued at \$5,037,051. The total value of the mineral products of New Mexico increased from \$8,176,229 in 1911 to \$14,391,355 in 1912. A large number of different minerals are mined.

Special Correspondence

DENVER, COLORADO

MEETING OF COLORADO SECTION A. I. M. E.—MINE TAXATION DISCUSSED.—COMMITTEE APPOINTED TO MEET LEGISLATURE.

Mine taxation was the subject for discussion at the November meeting of the Colorado section of the American Institute of Mining Engineers. This was the first meeting of the section following its organization at Colorado Springs last September, and there was an unusually large attendance, thanks to the active work of C. Lorimer Colburn, secretary, and the special dinner committee consisting of T. B. Stearns, R. A. Parker, and F. A. Bostwick. Following the dinner, at which W. J. Cox presided as toastmaster, the subject of the evening was taken up. William B. Hodges and D. L. Webb presented the principal papers of the evening, discussing the effect of the present taxing methods on the mining industry of Colorado, the present laws of the state,

BUTTE, MONTANA

EAST BUTTE PRODUCTION.—PROPOSED ZINC SMELTERS.—RE-OPENING THE NETTIE MINE.—LEACHING AT ANACONDA.—ORGANIZATION OF A MONTANA SECTION OF THE A. I. M. E.

Construction work at the mill and smelter of the East Butte Copper Mining Co. is responsible for the decreasing production of late. For the quarter ended September 30 there was produced 3,455,282 lb. of copper, as against 3,721,241 lb. in the previous quarter. The increased capacity of the plant, when remodeled, should soon offset this loss. There has been more or less talk of late that a zinc smelter might be erected in the Wyoming gasfields to treat the Montana zinc output. One of the present heavy charges on the zinc industry of Butte is the transportation of concentrate to the Mississippi Valley smelters. As the gas supply for these smelters is waning, it is not impossible that the industry may in part move west to Wyoming if the gas supply proves sufficiently dependable. One of the most significant developments of the month is the preparation by the Anaconda Copper Mining Co. to

and comparing these with the laws of other states and countries. A dozen or more members took part in the general discussion and the consensus of opinion seemed to favor a tax on net income from paying mines and on a basis of \$5 per acre on those not producing. Further discussion is scheduled for the next meeting and a special committee is to be appointed to consult with the legislature regarding taxation. Those attending the meeting were as follows: Victor C. Alderson, Philip Argall, Howland Bancroft, Francis W. Bosco, Fred H. Bostwick, Frank Shepard, Harry Brown, David W. Brunton, D. L. Webb, John A. Davis, Charles T. Carnahan, William R. Chedsey, Louis Cohen, C. Lorimer Colburn, William G. Dow, William J. Cox, Mason Lewis, J. B. Grant, Ernest Le Neve Foster, J. D. Gilchrist, Robert J. Grant, John Gross, Marshall Draper, A. J. Bamford, L. G. Hammond, J. Foster Syms, J. D. Hawkins, J. T. Hawkins, R. M. Henderson, Victor G. Hills, A. J. Hoskin, S. A. Ionides, George A. Kennedy, W. H. Leonard, James M. McClave, C. J. Moore, Richard A. Parker, William B. Patrick, W. C. J. Rambo, Russell B. Paul, Mr. Paul, T. H. Proske, J. C. Roberts, G. Sessinghaus, T. B. Stearns, Will B. Hodges, W. G. Swart, Henry A. Wentworth, Frank A. McGregor, T. M. Taylor, F. W. Traphagen, William F. Ward, O. R. Whitaker, Harry Wolf, C. H. Harrington.

reopen and explore the old Nettie silver mine west of Butte. The Nettie contains typical manganese silver veins. An attempt may be made to find new silver orebodies in the ground, but the natural assumption is that the Anaconda company will explore for zinc in depth and endeavor to find orebodies similar to those in the Butte & Superior property north of Meaderville. The developments here will be watched with interest. Should this property produce zinc ore of commercial importance, it is certain that many other similar veins in that vicinity will be explored in the near future. It is far from visionary to predict that Butte may soon become the largest zinc-producing district in the world.

The new leaching plant at Anaconda is expected to recover 10 lb. of copper from each ton of tailing treated. As the Anaconda plant handles 4,000,000 tons of concentrating ore annually, this may mean an additional saving of 40,000,000 lb. of copper per year. Also, as the tailing now accumulated amounts to between 20,000,000 and 30,000,000 tons, the leaching of this with a recovery of 10 lb. per ton predicts a large and profitable industry. The leaching method proposed will produce this additional copper at a cost of about 7c. per pound.

Boston-Butte Copper & Zinc Co. is the name of a new

\$1,000,000 company formed here to prospect a group of claims northwest of the Big Butte. So as not to fall into the predicament of the Butte & Superior company, which found zinc instead of copper, the company protects itself by attaching both metals to its name. A churn-drill hole in the disseminated copper deposit of the Butte-Duluth Mining Co. east of Butte has penetrated a rich body of sulphide ore at a depth of 180 ft. Samples from the drill-hole assay 30% copper. This ore was found in soft decomposed granite below the oxidized copper silicate zone. If ore of this grade should be proved to occur in large bodies, the finding of it may be considered one of the most important which has been made at Butte in recent years.

The Anaconda Copper Mining Co. is preparing to spend \$650,000 in the erection of a slime-concentrating plant consisting of 20 round-table machines of 20 decks each. The capacity of this plant will be 2200 tons of slime per day, from which a 50% saving is expected.

The Butte & Pensacola Copper Mining Co., of Cascade county, is said to have made an important find in its property in the Little Belt mountains. Great Falls business men are financing a company to drill for oil near the town. The reported success of drilling operations to the north of Calgary, Alberta, encourages them in the hope that similar conditions may be found near Great Falls.

The Anaconda Copper Mining Co. seems to have fallen into a good thing near Eudora, in Flathead county. Surface croppings assaying 30 to 40 oz. silver per ton have been found for a length of 800 ft. and a width of 150 ft. Work on the find is to be pushed vigorously. The land was bought by the Anaconda company some years ago from the Northern Pacific railway for its timber value. An English company has taken a lease and bond on the old Emery mine near Deer Lodge, in Powell county, and will explore it further. The new company goes by the strange name of Butte Daryumsu, Ltd.

Montana members of the American Institute of Mining Engineers met at Butte, October 17, and organized a local section. Meetings will be held twice yearly, in February and October. It was voted to participate with the Spokane section in a joint meeting to be held at Wallace, Idaho, November 15 and 16. The following officers were elected: E. P. Mathewson, of Anaconda, chairman; Frank M. Smith, of Helena, vice-chairman; D. C. Bard, of Butte, secretary. These with Oscar Rohn and James L. Bruce, both of Butte, constitute the executive committee.

MANHATTAN, NEVADA

MINING OPERATIONS AT THE MANHATTAN CRESCENT.—DEVELOPMENT AT THE WHITE CAPS PROPERTY.—BIG PINE COMPANY.

Mining operations on the Crescent property continue to develop more ore. Ore from the property is milled twice a month at the War Eagle mill. The ore is being mined from the slopes between the first and second levels, and assays better than \$20 per ton. The ore in the Crescent is found throughout the schist and in many places the ore is from 50 to 60 ft. in width. The Reilly Fraction still continues in the front rank of ore producers of the district. At the present time the mill is treating at the rate of 15 tons per stamp for each 24 hours running time. The highest single day's run was 130 tons, and during this run the mill had to be shut down for lack of ore in the bins. A 16-mesh screen is used in front of the stamps, and a good recovery is made from the plates below the batteries. The water for the mill is now being taken from the Big Four shaft.

The mill dumps on the White Caps property prove to have been considerably underestimated. The measurements of the ore dumps prove that they at present contain 4800 tons of ore. The average of the dumps, as nearly as can be figured, will be \$15 per ton, making the ore of a gross value of \$72,000. Three-fourths of the ore on the dumps has been mined during the past 90 days. The ore in slight in the mine shows a tonnage of considerably more than has been mined. A very interesting feature of the White Caps is that from the bottom or 300-ft. level the grade

of ore, as exposed in the great east orebody, is of higher grade than on the 165-ft. level, and nearly twice as rich in gold content as the ore close to the surface. Unquestionably the next hundred feet in the property will prove one of the big orebodies of the district. The mining work now being done by the White Caps company consists of the cross-cut to make connection with the top of the new vertical shaft, from the 165-ft. level a distance of 45 ft. being necessary to make connection. When connections are made, the shaft will be completed to the surface, the timbering and work being done from the 165-ft. instead of from the 300-ft. level. Upon the completion of the shaft and the installation of adequate machinery, the production from the White Caps can easily keep a 10-stamp mill running at capacity.

The operations at the Big Pine property by Mushett and Wittenberg, lessees, are proving that the heart of the great zone of enriched schist which follows the general direction of the Big Four hill, and has been proved in the Big Four to reach a depth of at least 500 ft., is to be found in the Big Pine. The near future developments on this property will be of immense interest, as now that the mill owned by the Manhattan Milling & Ore Co. has been purchased by the operators of the Big Pine, cheap milling facilities are available. The splendid record established by the Reilly Fraction, milling at the War Eagle mill, should be duplicated by the Big Pine. At present the item of transportation is the main expense, and without some system of tramways it is hard to reduce the haulage cost. Perhaps the coming year will see an aerial tramway in operation at Manhattan.

TORONTO, CANADA

ONTARIO BUREAU OF MINES RETURNS.—PROGRESS AT THE DOME MINES.—NIPISSING PRODUCTION.—NEW DISCOVERY AT THE PENN CANADIAN.

Returns made to the Ontario Bureau of Mines of the gold production for the first nine months of the year, give a total value of \$3,281,027, being an increase of \$2,163,692 over the corresponding months of 1912. Of this amount all but \$174,777 came from the mines in the Porcupine area. The monthly statement of the Dome Mines for October showed a total tonnage of ore treated amounting to 12,370 tons, which is considerably in excess of any previous month's record. The value of the output was \$118,000 and the average recovery for every ton milled \$9.54. Development underground is making satisfactory progress, driving having been accomplished to the extent of 573 ft., of which 100 ft. was on the 425-ft. level of No. 1 vein, the richness of which is well maintained. A winze is being sunk to the 550-ft. level. The McIntyre during October milled 3900 tons obtaining a 96% extraction, the ore averaging \$10 per ton. The mill is now treating 150 tons per day. During October the Nipissing mined ore of an estimated net value of \$218,772 and shipped bullion from its own and customs ore of an estimated net value of \$348,612. At the Meyer a branch vein has been found on the fourth level near the Keewatin contact, carrying one to two inches of 2000-oz. ore. The high-grade mill treated 180 tons of ore. The Pan-Silver, owning 100 acres adjoining the Beaver and Timiskaming mines, recently found a small vein which, when followed up for 23 ft., widened out to 5 in. of high-grade ore with wall-rock of about 3 ft. in width carrying milling ore. Another good discovery of a 3-in. vein carrying free silver has been made on another part of the property. The Penn Canadian has opened the new vein recently discovered on the 300-ft. level for 35 ft. and it continues good. The production during October was 60,015 oz. Cross-cutting has been undertaken to tap the vein on the fourth level. The financial statement of the Caribou Cobalt, covering the period from March 31 to August 31, shows a total production of 185,228 oz., having a net value of \$97,017. The net earnings were \$38,773. The ore reserve is estimated at 20,000 tons of milling ore, which with the associated high-grade ore gives approximately 580,000 oz. of silver. The Crown Reserve has declared its monthly 2% dividend, but withheld the extra bonus which was anticipated. The Company has taken options on the Porcupine Gold, generally known as

the Vipond, and the North Thompson in the Porcupine area. The affairs of the Chambers-Ferland are in litigation, Harry Cecil having applied for an injunction on behalf of himself and other shareholders to prevent the sale of the property to the Northern Concentrators, Ltd., on the ground that recent meetings and acts of the Company have been illegal. On the Giroux claim in South Lorrain, where previously no valuable discovery had been made, a small silver-bearing vein has been found in an old trench.

The Albert Oil Shales at Sussex, N. B., after a protracted investigation by leading oil experts has been taken over by a syndicate of British capitalists. The property is valued very high and preparations are being made for the erection of an extensive plant.

BLACK HILLS, SOUTH DAKOTA

HOMESTAKE PLANNING STEAM PLANT AND NEW HOIST.—PRODUCTION FOR THE YEAR.—LABOR UNION LITIGATION.

Upward of \$250,000 is being spent by the Homestake Mining Co. for improvements being made during the present year, and according to plans outlined for next year's work the sum expended will be fully as large. For the coming year the big items of expenditure will be for a steam auxiliary to the Spearfish hydro-electric plant and a new hoisting equipment at the Old Abe shaft. For the first mentioned, the work of clearing the site, preparatory to excavation, has already been begun. A large structure to house the boilers will be erected on land just north of the Homestake stables at Lead. This building will contain boilers of a total of 3000 hp., steam from which will be used both for driving the generating units for the operation of the new hoist and for various minor purposes in the nearby mills. The generating station will be across the street and adjoining the new concrete distributing station from which electric power from various sources is distributed to the various plants of the Company. Turbine engines direct-connected to high-voltage generators will be used. At the Old Abe shaft the Company is to erect one of the finest hoisting plants in the West, and the best on its property. The engines will be of sufficient power to hoist material from the deepest point to which may be driven in many years. It will probably be about April 1 when work on this hoist will start, and since the machinery has been designed and specifications for the new plant are in the hands of the contractors, there will be no delay once work is begun. The largest item of the Company's improvement expenditure for the present year has been for the construction work on Recreation Hall, a building in Lead which will be devoted entirely to club purposes, and free to employees. Among the conveniences of the building will be library and reading rooms, billiards, bowling alleys, baths, gymnasium, etc., and in a wing will be one of the finest opera houses in South Dakota. The walls and roof of the building are nearly completed, and in a short time the structure will be entirely enclosed, so that the finishing work on the interior will proceed to a rapid completion despite winter weather. Another important improvement of the present year was the construction of a large and well appointed change-house at the Ellison shaft. This building was constructed of concrete and is the finest structure of its kind on the property.

That a greater tonnage of low-grade ores is being mined in the Black Hills, with a slightly smaller bullion production than last year, is the information conveyed in the annual report of Otto Ellerman, State Mine Inspector, which covers the year that ended on October 31. The total gold and silver product was \$7,497,100, while miscellaneous mineral products amounted to an additional \$248,135. There are a total of 2960 men employed in the mines of the Black Hills. During the year there were only nine fatal and eight non-fatal accidents. This, in comparison with other states where there is mining, places South Dakota at the head of the list in comparative freedom from accidents, according to Mr. Ellerman. At the Homestake, with 2250 employees, there were only five fatalities and seven injuries. He gives it as his belief that most of the accidents happen to 'new' men, to whom was not given sufficient warning as to the caution necessary. He also calls

attention to the fact that many properties are idle for lack of sufficient capital to put them on a paying basis, and that all the operating mines are in good condition and making many new improvements which will result in increased tonnages. Of the miscellaneous minerals produced in the district, the mica was worth \$6950; gypsum products, \$61,735; tungsten, \$2000; lithia ores, \$19,500; building stone, \$106,000; coal, \$12,000; and miscellaneous, \$40,000. The following table shows the bullion product and tonnage for the year that ended on October 31:

	Bullion.	Tonnage.
Homestake	\$6,250,000	1,533,000
Golden Reward	423,840	53,712
Wasp No. 2	286,930	163,380
Trojan	280,518	68,106
Bismarck	50,000	31,980
New Reliance	73,323	27,100
Mogul	44,117	5,593
Placer (estimated)	2,000
Miscellaneous	86,372	10,600
Totals	\$7,497,100	1,893,471

South Dakota's new 'blue sky' law was enacted by the last legislature and went into effect on July 1, under the provisions of which corporations desiring to sell stock, bonds, or other securities in the state for the purpose of financing their operations must secure permission from the State Securities Commission, which is headed by the State Bank Examiner. The law provides that certain information must be furnished the commission, some of which seems rather irrelevant. Following is some of the information required: A list of directors and officers, with their known financial worth, the amount of stock held by each and the price or compensation paid by each for his holdings, and the salary paid him by the company for the services he performs; a complete list of stockholders, with the price or compensation paid by each for his holdings; a copy of the by-laws; copies of all contracts or agreements in force; a statement as to the business to be undertaken, its probable cost, etc.; a balance-sheet of the corporation's books, and considerable other material along similar lines. After this is furnished and is reviewed by the commission the next that the corporation hears is that the commission desires about \$50 to pay the expenses of a man to 'view the assets.' Inasmuch as the men sent out know practically nothing of mining, this provision is regarded by the mining corporations as a joke. But eventually the commission issues permission for the corporation to sell a certain block of stock, bonds, or other securities at a certain price and under certain conditions. But, should for any reason the directors or those in control of the corporation desire to change the price or terms, authority must be secured to make such change. Altogether, there is a great deal of 'red tape' connected with the statute, and its benefits are problematical.

Owing to the failure of Congress to provide funds for transportation charges on bullion between assay offices and mints, the bullion depositors at the Deadwood office are required to pay the express charges on their deposits. This amounts to 80c. per \$1000, and is not an exorbitant sum. The matter of appropriation was fought out recently in Congress when the deficiency bill was up for consideration. It is hoped that at the regular session, commencing in December, the error will be rectified, so that business at the Deadwood office can be conducted as in the past, as this office is a great convenience to the mines of the Black Hills district.

In a case recently heard in the local courts, wherein the Western Federation of Miners attempted to secure possession of the building of the Lead City miners' union, the decision, partly in favor of the local union, was in part as follows: That the Lead City miners' union was the sole owner of the property; that the deed given to C. H. Moyer, as president of the Western Federation, was in law a mortgage only against the property and for \$8100; that this mortgage was subject to a prior mortgage for \$25,000 given the Butte, Montana, union in 1911; that the Butte union, through the Federation, had forwarded to

Lead, as relief, \$25,000, the consideration for the giving of its mortgage; that no application having been made to the court to foreclose these claims against the property, the court had nothing further to do than to declare the effect of these instruments. The litigation grew out of the late labor struggle in the Black Hills, at which time the Western Federation paid out, according to evidence introduced, over \$409,000 in benefits, and in return for a portion of which attempted to secure title to the building at Lead, which is worth over \$50,000. The Lead union admitted an indebtedness of \$13,100 to the Butte union, and will probably appeal from those parts of the decision making it liable for further sums.

Lawrence county has just received from the federal government the 10% of receipts from sale of timber in national forests which recent legislation by Congress provides shall be turned over to the county treasury in which the timber is cut. The payment, which covers the past fiscal year, amounts to \$4056, of which \$406 will be placed to the credit of the school fund of the county, and the balance, \$3650, to the road fund. Splendid progress is being made by the Mogul Mining Co. in the construction of its new mill near Terry. The building is nearly all enclosed, and a few more days of good weather will see everything under shelter. The constructing engineer has 25 men at work, and believes that everything will be completed and the plant in operation by the middle of January. Operations have been suspended at the Wasp No. 2, and it is not likely that they will be resumed before spring. A shortage of water is given as the cause.

NEW YORK

QUARTERLY REPORTS.—RAY, CHINO, UTAH.—BRADEN SHOWS DELAY.—LA DURA CLOSED.—BUTTE & SUPERIOR.

The feature of last week was the appearance of the Quarterly reports of the big 'porphyry' copper companies. The Ray showed operating profits for the three months ended September 30, of \$661,085. There was a slight decline in the output of copper, as compared with the preceding quarter, and a marked decline in operating profits. Figures as to earnings have a certain amount of indefiniteness, however, as they are based on a selling price of 15c. for copper and the metal in transit is inventoried at 13.15c. Dividends so far this year have amounted to \$1,087,560 on the 1,450,000 shares outstanding. The average cost per pound of copper was 10.155c., as compared with 9.56c. for the preceding quarter, and 9.51c. for the first quarter of the year. Alterations on the mill during the quarter, which were charged to operating expense are responsible for the increased cost.

Chino yielded 15,187,000 lb. copper during the third quarter. The average grade of the ore treated during the quarter was 2.23% and the mill recovery 67%. This is lower than the usual recovery and the September output showed a marked decline. One of the technical problems at Chino is the irregular character of the orebodies, as sulphide ore occurs in some places above the oxides and at others below them. In order to mine economically it is necessary to go ahead and take the ore as it comes. As a result the mill feed shows big fluctuations as the steam-shovels pass out of the oxides into the sulphides, or the reverse. When the property is more fully stripped it will be possible to counterbalance this to some extent by pushing the shovels in one place and holding them back in another, but it will always be more or less of a problem to the management.

The Utah Copper reported a yield of 32,287,452 lb. at a cost of 8.187c. per pound. The ore treated averaged 1.25% copper, of which 0.8% was recovered and 0.45% lost in the tailing. The net earnings for the quarter amounted to \$2,206,399, leaving a net surplus over the payment of the quarterly dividends of \$1,186,695. The average tonnage handled by the two mills during the quarter was 22,000, and during September the average was 24,000 tons per day. The present situation of Utah Copper is the logical outcome of its policy, and it is interesting to note that by increasing the tonnage handled as the grade of the ore goes down the management is able to keep the production cost

down. It is stated that it is intended to accumulate a reserve so that the Company will hereafter carry its unsold copper until it is disposed of. It is the general practice for companies on shipping blister copper to the refineries to borrow from their banks on the metal as security. Shipment, refining, and selling require about three months, and the interest charge on the cost of the copper for this period is thus an element in the cost of production. Naturally, the bank rate on money advanced is higher than the interest paid upon corporate funds deposited with it, and it is a saving, therefore, for a company to carry its own copper until it is sold. As the Utah Copper Co. has unsold copper amounting to about \$5,000,000, Nevada Consolidated over \$3,000,000, and the other big producers in proportion, the interest charge question is of not a little importance. Nevada Consolidated reports an output of 15,835,563 lb. for the quarter, a good deal of a decline from the preceding one. The Cananea Consolidated made an output in October about equal to the preceding months. This is only at part capacity, but the Company is doing better, following the troubles at the plant earlier in the year, than was expected in some quarters.

The long period of depression which the Braden has undergone exhibits itself in the announcement that the time for the conversion of its 7% bonds has been extended until March 1, 1916. The expected early improvement in the results attained at the property still seems to hinge, and the Hardinge mills are still expected to do great things, while the hopes for the improvement to be attained by the Minerals Separation process are still green. Exploration work continues to add to the ore reserves, but this is only partly consolatory for poor operating profits. Braden seems to be only repeating the history of numerous other properties where it has been found that thousands of miles of distance between the head office and the mine constitute a very real handicap in equipping and operating it. The trouble with the American companies is that they try to operate such properties under the direct supervision of the technical staff at the head office, English companies get better results by putting technical operations completely in the hands of the local manager, while the London office occupies itself with the financial end of the mining game. Excellent reports come from Chuquibambilla, where drilling work is stated to have raised the ore reserves of the Chile Copper Co. to over 200,000,000 tons.

The Mines Company of America has had to stop work at its La Dura property, and the manager, Ben T. Wells, has returned to El Paso. For a long while railroad communication with the property has been cut off and shipments of supplies and bullion have been made by way of the Creston-Colorado. Now that its operations in Mexico have been brought nearly to a standstill, the Mines Company has been pushing its examination work in the United States in the search for good properties on home soil. W. B. Thompson and W. H. Aldridge are interested in the Company and seem to furnish the chief impelling influences as the controlling interests, steel and iron men, are somewhat unfamiliar with the metal-mining business.

The failure of H. B. Hollins & Co., members of the New York Stock Exchange, created comparatively little stir in the financial district. The firm had no connection with mining shares, and of recent years has acted more as a promoter of industrial enterprises, one of the firm being president of the Vacuum Cleaner Co. The firm has been impetuous for years and its failure has often been rumored.

The Butte & Superior continues to make good profits while its infringement suit drags along. Judge Bourquin has refused to enjoin the Company from operating, but has ordered it to give a bond. The Company officials now claim that the flotation process as now in use is of their own devising, but it scarcely seems possible that they will be able to do other than eventually to give in and pay the royalties demanded by the Minerals Separation.

Samuel Montagu & Co. report a net influx of gold at London for the week that ended on November 5, of £61,000. The net import into India in October was £1,687,266. Rand cables to London announce additional regulations regarding dust prevention in mines. Shaft bottoms are to be washed with a hose to facilitate finding missed holes.

badly hit. The railroad was washed out for about two miles.

FAIRBANKS

According to figures that have been compiled, the output of the Shushana district will amount to about \$74,000. This, however, is greater than the first season's operations in the Fairbanks district. When it is considered that the stampede did not take place until near the close of the season, the output exceeds that of many of the Northern camps and indicates that big things may be looked for from that district as a result of the prospectors' activities who are wintering there. The miners have been engaged in getting into shape for winter by building cabins and getting in a supply of wood. Food was scarce, but the arrival of winter will cause prices to drop, as there are hundreds of tons of provisions at several points within distance of the 'diggings.' Latest arrivals from the district state that the benches, which have been prospected, are everywhere showing encouraging results, although no one has as yet reached bedrock owing to the ground being frozen. The bench ground on Gold Hill is known to carry gold averaging 35c. per yard.

PORT WELLS

A contract has been entered into by M. J. Callaghan to drive an adit 200 ft. long into the ground owned by Peter Black and William Hogan, on Harriman ford. Mr. Callaghan is to receive a one-third interest in the property and has also an option to purchase at a price of \$50,000. The ground is within 300 ft. of tide-water and both timber and water-power are available. The lead at the surface is five to ten inches wide and assays \$50 per ton in gold. The ore is a white quartz and the vein parallels an acid dike about four feet wide. Mr. Callaghan lives at Vancouver,

but has provided for the driving of the adit this winter. Harriman ford is an arm off of Prince William sound, northwest of Valdez. It was named in connection with the explorations made by the E. H. Harriman party. The rocks of the district are similar to those at Valdez.

VALDEZ

The Midas mine, which is near Valdez, has been sold to the Granby Con. M. S. & P. Co. and a crew will be set to work developing and mining at once. It is understood that the Company is contemplating the establishment of steamship service to southwestern Alaska.

ARIZONA

GILA COUNTY

Development work at the Iron Cap Copper Co. is progressing in a satisfactory manner. The stope on the 650-ft. level is 400 ft. long and the ore is of good quality. The east drift on the 650-ft. level is now within 20 ft. of the Eureka shaft of the Arizona Commercial company, and with this connection made, ventilation will be greatly improved. The raise from the 800-ft. level to connect with the 650-ft. level will be completed some time this month.

Work on the mill is progressing rapidly and the steel work is nearing completion. The main shafts are now being overhauled preparatory to concreting. The Joe Bush shaft is being worked occasionally. Within six weeks more both the main east and west shafts should be connected on the sixth level with the other workings. During the month of October, development work underground was greater than the previous month by about two-fifths and about twice as great as the month of August. In October there were 17,182 tons of waste and 6866 tons of ore hoisted, making a total of 17,544 tons hoisted and an advance of 2061 ft. of development work done.

At the Superior & Boston the most notable change instituted since Mr. Tinker, the superintendent, assumed charge of the property, is the manner of doing away with the expense of timbering as the ore is mined between the 600 and 800-ft. levels. Formerly the ground was timbered as the ore was stoped upward, but by the new arrangement the only timber to be used will be that required in the raises that will be kept open between the levels as air channels and means of extracting ore and rock broken in development work. As the ore is mined along the vein the waste will be filled in behind and whatever rock is needed for complete filling will be sent down through the raises as the development and exploration work above the 600-ft. level is carried forward. Through this manner of obviating the necessity of timber the operating costs will be reduced to a marked extent. As the ore is stoped eastward the lack of change in its general appearance and width makes it seem probable that it will maintain its average size in that direction. The 1000 drift eastward is at present in the altered rock characteristic of the faulted zone. Diamond-drilling is proceeding eastward from the face of the east drift on the 600-ft. level to explore the vein in that direction. On the 1000-ft. level a small pump is being installed to pump drinking water to the surface, an abundant supply of excellent water being available at that level. The mine's output of ore remains at somewhat more than three carloads per day.

PINAL COUNTY

Operations at the Ray Consolidated Copper Co. during the past quarter have been somewhat impeded by a shortage in the water-supply, which is reflected in the report for the quarter ended September 30. Steps have been taken which will prevent a recurrence of this condition and a period of increased activity is looked forward to. In spite of the shortage of water, the results were not much below those of the June 30 quarter.

A comparison of production and cost is shown in the following table:

	Sept. 30, '13.	June 30, '13.	Sept. 30, '12.
Tons treated	575,190	587,877	429,411
Grade, per cent....	1.72	1.7	1.61
Copper, pounds ...	12,969,120	13,402,394	9,295,818
Cost, cents	10.15	9.56	10
Total net profit...	\$661,085	\$726,759	\$650,713
Assumed copper price	15c.	15c.	17.13c.

YAVAPAI COUNTY

A report from Prescott states that an English company has arranged for the purchase of the Nigger Brown and Henrietta mines, and preparations are being made to conduct operations on a large scale. The deepest working on the Henrietta is a 550-ft. shaft, but the ground above this level is far from worked out. It is the plan of the new company to complete the lower adit, now in 1300 ft. and within 200 ft. of cutting the ore-shoot. The completion of the adit will open virgin ground 200 ft. below the present workings. The Nigger Brown has a 290-ft. shaft. In the bottom the ore-shoot is 9 ft. wide and the average in all the workings is \$35 per ton. A mill will be placed on this property as soon as it has a sufficient tonnage of ore developed.

CALIFORNIA

BUTTE COUNTY

(Special Correspondence.)—No. 1 dredge of the El Oro Gold Dredging Co. has finished its area of gravel and is now being dismantled. It is probable that the machinery will be sent to a property in another state, or another part of California. The Indiana company's dredge is to be moved to Michigan Bar, in Sacramento county, and may be started early next year. No. 1 boat of the Pacific company was partly taken to the American river, near Auburn, Placer county, where a complete dredge is in operation on river bars. The Oro Water, Light & Power Co.'s boats are working south. The Company has a large area of ground some distance from this point to be turned over. The Pennsylvania dredge recently cut through a road, and is operating in a new tract. A new bucket-line is being installed on the largest of the three dredges of the Natomas Consolidated on the Feather river. Old dredge tailing from the Oro Vista boat, owned by L. Gardella, is being leveled by a drag-line scraper. This area is about five minutes' walk from the town centre.

Oroville, November 17.

SACRAMENTO COUNTY

(Special Correspondence.)—During the first week in November, the dredge of the Ashburton Mining Co., operating near Natoma, was stopped for good. The boat had been working for six years, and the hull, bucket-line, and stacker got into bad order, and as the Company only had a few acres more to turn over, the gold recovered from this area would not yield enough profit after the dredge was overhauled. The electric motors, buckets, ladder, and stacker are now being dismantled. With $7\frac{1}{2}$ -cu. ft. buckets, the boat handled 1,000,000 cu. yd. of gravel yearly, and has had a maximum month of 165,000 cu. yd. The average gold content was 11c. per yard, and the Company has found the work very profitable.

Natoma, November 14.

SHASTA COUNTY

(Special Correspondence.)—C. R. Russell has taken personal charge of the Russell placer claims at Igo and is working excellent gravel with the drag-line machine. As soon as sufficient water is available, a part of the ground will be mined by sluicing. It is reported that the Shasta Dredging Co. is about to test the gravel on the Gibson ranch with a diamond-drill. The property is on Clear creek, on the outskirts of Redding. The Field Process Co. is completing the building of its experimental smelting plant near Redding. The first test will be on a shipment of sulphurous ore from the Balaklala mine, Frank M. Leland, the manager, having donated the material for this purpose. The refrigeration plant is in position and the balance of the equipment will be installed as soon as it is received from Richmond. A. J. Field, the inventor of the process, plans to recover the sulphur in a solid frozen state, using liquid sulphur dioxide, produced from the ore, as the refrigerating

agent. It is expected to make the initial experiment about November 20. The Balaklala Copper Co. is installing precipitating tanks for the recovery of copper from the mine waters. Tests indicate that the Company may expect upward of \$1500 per month from this source. From 50 to 60 tons of ore is shipped monthly to the Mammoth smelter, the ore containing about 3.5% copper and \$2.50 in gold and silver per ton. The hoist is in position at the Donkey mine, near Ingot, and deep shaft-sinking is about to start. Redding, November 3.

The work of hauling 300,000 lb. of steel pipe from Redding to Stuart's fork, where it will be used by the La Grange Mining Co., is progressing. The pipe will be used for the construction of a siphon to carry water across the Stuart Fork cañon. The Company has a 36-in. siphon, but that does not carry water enough to meet the demands of the mine, so a supplementary siphon is to be constructed. One arm of the siphon is 1300 ft. long, the other 1100 ft. The point of delivery is ten miles up the stream from Minersville. It takes the teams nine days to make the round trip. Between Minersville and the siphon site, Stuart's fork, a turbulent stream, has to be forded nine times. Six 8-horse teams are rushing the work of delivery so as to put the pipe on the ground before winter.

SIERRA COUNTY

It has been reported that negotiations have been entered into whereby the El Dorado mine will be purchased by Butte, Montana, interests. The mine is an early-day discovery and has at times yielded small fortunes from surface pockets, the aggregate yield amounting to several hundred thousand dollars in gold. Yet the mine is a mere prospect in development, though it has an adit 1000 ft. long which was run upon the vein from its Kankaka creek outcrop. It is a north extension of the Croesus mine at Plumbago and carries the typical arsenical sulphurettes of the district and also free gold. The new management will drive on the vein for new shoots as well as sink and raise on the old ones. The property is equipped with a 10-stamp mill operated by water power.

YUBA COUNTY

A complaint has been filed against the Consolidated Willow Mining Co. by George W. Lister, in which it is asked that the directors of the Company be ordered to pay for thousands of dollars' worth of stock which they are accused of having illegally received, and to show what disposition has been made of \$110,000 which was paid into the treasury. The mining property is at Weeds Point, in Slate Range township, Yuba county, and comprises the Horse Valley placer mine, Four Hundred placer mine, the Bull of the Woods mine, and the Debris Dam of the Horse Valley creek, the Horse Valley or Upper Weeds Point ditch, heading in Oak valley, and a reservoir used in connection with the Horse Valley mine. According to the allegations, shares in the corporation to the amount of \$130,000 were sold. The mine was worked until 1909, at which time active operations were suspended. It is stated that but \$20,000 was expended in operating the claims and that no accounting has been made of the remaining \$110,000 in the treasury.

COLORADO

EAGLE COUNTY

One of the richest discoveries which has been made in the Eagle district was recently made at the North Dakota mine, when a vein 5 ft. wide was found which assays 460 oz. silver per ton. The vein was found at the surface, and the lessees believe that it will continue with depth. This mine is near the Lady Belle property and is being operated under lease by the Marion Henry Mining Co. The Lady Belle mine is shipping a carload of ore every other day.

LA PLATA COUNTY

The Eagle Pass Mining & Milling Co. is making good progress. The work on the adit continues, and a good grade of ore is at present showing in the breast. The Bulldozer is still doing work on the cross-cut and making fair progress. The Copper Hill was incorporated for \$500,000 and has \$90,000 cash on hand for development work. The

Company is working a full force at excavating for a power-plant and other buildings at the mouth of Bed Rock and expects by the first of January to have the plant in operation with sufficient power for a 6-drill force. The diamond-drill between Bed Rock and Madden is still in operation, but has revealed nothing.

MESA COUNTY

A rush to the recent gold discoveries near Colibran has started from all parts of the state. Scores of men are coming in from De Beque on every stage and the mining camp in Clover gulch is taking on the appearance of a tented city. Over 150 claims have already been staked, and the claims extend for 14 miles up and down Clover gulch, while prospectors are now staking other claims on Kimball creek. The advance prospectors from the Eagle district report that they will be followed by scores of other prospectors if early reports of discoveries are borne out. Additional assays of ore have been made and show from \$138 to \$150 per ton, with indications of a streak of uranium. Merchants of Colibran have ordered large quantities of tents and other camp supplies.

TELLER COUNTY

It is believed that the coal situation in the Cripple Creek district will be serious if the strike continues another 30 days. It is said that in that time the coal shortage will have reached such a stage as to necessitate the closing of several of the larger mines. At the present time the cost of operation has been greatly increased owing to the fact that nothing but lignite coal can be secured in any quantity. As most of the mines are fitted with hard coal furnaces, the lignite coal gives poor service. Already many of the mines in the Cripple Creek district are practically without a coal supply, and the larger power-plants at Pueblo and Canon City are facing a coal famine which threatens to close them. Should this happen the mines of the Cripple Creek district and the smelters at Pueblo would be without power. Even the most optimistic of the mining men admit that the present situation cannot be continued beyond the first of the year without harm to the industry.

It is reported that a new ore-shoot has been discovered in the Burns shaft of the Acacia Mining Co. Assay tests on two feet of the ore show as high as \$500 per ton, but the average value per ton is probably \$50. The full width of the vein is not yet determined, though there is good reason to expect that it will be four or five feet wide at the point of discovery, and one wall has yet to be cross-cut. Free gold occurs in the vein quartz. The vein is supposed to be an extension of a rich vein that occurs in Stratton's American Eagles mine, a nearby property. The run during the past month at the Dante Gold Mining Co. was curtailed by a break-down of the machinery in the crushing department of the mill. In breaking the ore for treatment at the Dante mill, a rich ore-shoot has been opened and is now under development, and shipments from the new orebody will materially increase the profits resulting from the operation of the mine and mill.

MISSOURI

JASPER COUNTY

Announcement has been made that sufficient funds have been raised to keep the pumps going at the Providence property, and it is believed that the present equipment is sufficient to keep the water below the levels that are being mined in the adjacent properties. In most instances each mining company operating in the threatened district pledged \$50 per month toward the pump fund, and most of the landowners subscribed \$100 per month. In this way a fund of nearly \$1000 per month has been raised, which will pay the actual expense of running the big pumps in the Providence mine. Had the operators failed to raise the fund of \$1000 per month, the Providence Mining Co. had determined to take out its pumps and the whole district would have been flooded.

The Sapulpa mine, which is situated on a lease of the American Zinc, Lead & Smelting Co., has been leased by Webb City interests. The Company has developed a large area of mineralized ground on the 40-acre lease and the mine promises to be a big producer. There is a 200-ton

mill on the lease and ore is hoisted from three shafts. There is a high face of rich ore in the drift, it is said, and drill-holes near the mill show that a wide area of rich ground remains to be mined. The mill is in splendid condition and is equipped with modern concentrating machinery. Operations will be conducted at the Sapulpa on a large scale and the output of the mine is likely to be greatly increased.

Slides of earth, which have recently occurred at the property of the Daylight Mining Co., have endangered the mill. Two weeks ago about 300 tons of earth fell, this slide occurring opposite the mill, and during the past week several slides large enough to alarm the owners of the mill have occurred. The Daylight mine is perhaps the most unique in the district, in that all the workings are in a large cave. Considerable amounts of zinc and lead ore are contained in these slides.

The Wilson Mines Co. is at present producing a large tonnage of lead and zinc ore. For several months the mine has been the second greatest producer in the Duenweg district, the Coahuilla alone excelling it in point of production. The Company is mining a rich ore deposit at a depth of 170 ft. and hoisting ore from two shafts. The mine is equipped with a splendid concentrating plant.

The Durston Mining Co. obtained a lease on part of the Luscombe and McElroy land, southwest of Galena and near the old New Century mill, some time ago, and it was decided that a mill should be erected on the ground, but the plans were not formulated until recently. Mr. Edwards, the manager, has succeeded in finding a suitable site, and the ground work and the foundation will be started at once. The Company expects to move one of its mills from near Joplin to this place, and it is believed that by the time the mill is torn down the foundation and other work being done at Galena will be completed and the mill may be erected without delay. The Luscombe and McElroy land has been mined only on a small scale. This Company expects to mine it thoroughly and it is said some good ore exists there.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—The leaching process being tried at Anaconda is so far giving excellent results. The Laist method of precipitating copper by means of iron reduced from powdered ore by coal is giving satisfaction and may prove of wide importance. A McDougall furnace is being prepared for use in this connection in an effort to get a continuous process. A little copper is volatilized in the chloridizing roast, but an electrical precipitating unit is being installed to recover this and such acid as is formed in roasting.

Butte, November 8.

NEVADA

ESMERALDA COUNTY

Shaft sinking has been resumed on the Silver Pick Consolidated property, and three shifts are being employed for this work. The shaft is down a little over 400 ft. and the bottom is apparently in a vein of large size. It is planned to continue the shaft to a depth of 1000 ft., but some lateral work may be done at a depth near the present bottom of the shaft.

Development work at the Florence Goldfield property is satisfactory, according to report, although the Company has ceased shipping ore to the Bonnie Clare mill. It has not been definitely announced whether the Company will resume shipping to this plant, but it is stated that there is a large tonnage of excellent milling ore in the mine and a good profit can be made in the treatment of this ore. During the period in which the Florence company was treating ore at Bonnie Clare it is said to have effected a recovery better than 85%. The presence of copper in the ore coming from some parts of the mine prevented as high a recovery as was at first expected. Some of the ore yielded a recovery in excess of 90% by simple crushing, regrinding, and cyanidation. The mine is said to be in excellent condition, with some encouraging new developments on three levels, and in addition to the ore recently placed in sight there are

quantities of mill ore stored in old mine workings and on the old dumps.

Work at the C. O. D. Consolidated property is at present being confined to the 30-ft. level, which level was started from the Gold Bar shaft and has been connected with the Victor shaft at a depth of about 350 ft. Quantities of good milling ore have been exposed on both levels, although some of the ore is refractory and may require other processes of treatment to successfully recover the mineral content than those now in use in the district. At a point near the Victor shaft on the 300-ft. level, seams of shipping ore are exposed and several shipments have been made that have yielded a good profit. It has been the plan of the Company to block out its milling ore in case a sufficient tonnage can be made available to erect a mill of 50 tons daily capacity.

EUREKA COUNTY

The mill construction at the Buckhorn mines is about a month behind the scheduled time, owing to the severe storms that have prevailed during the summer months, but both mill and power-plant will be in readiness to be tried out about December 1. The power-plant is situated at Beowawe, and will be operated by petroleum generators, oil to be delivered at the plant in tank cars. The mill and power-plant will cost in the neighborhood of \$400,000 when complete. Approximately \$500,000 has been spent on the development of the mine. Fully \$1,000,000 will have been expended upon the Buckhorn Mines Co.'s properties before any returns can be realized, in addition to the purchase price of the mine. The mill will have a capacity of 350 to 400 tons of ore per day and a large tonnage is already blocked out. Operations will be conducted largely through tunnels, and the ore can be brought to the mill at an unusually low cost. It is estimated by the Company's engineers that with the plant operating on a normal basis a net profit of \$50,000 per month will be realized for a long time to come.

HUMBOLDT COUNTY

It is reported that the vein on the Big Four lease of the Rochester Mines Co. has widened out to 12 ft. and contains shipping ore which will assay \$40 per ton. The ore is in the bottom of a 150-ft. winze from the main level which was driven to cut the vein. On the south drift at a point 200 ft. from the tunnel level a lens of ore 10 ft. wide was found. It is said to average more than \$100 per ton, and in places free gold is seen. This is the first time that free gold has been found in the adit and is considered indicative of greater richness at increasing depth. For some time there has been a small output from this property, because of the dead work that was being done to develop the property at depth.

LYON COUNTY

The following report has been received from the general superintendent of the Nevada-Douglas property at Ludwig, Nevada. "I am glad to report that development work on the Company's properties continues to bring to light highly gratifying conditions. In the Ludwig the 8th level advanced 81 ft. during the month of October. In the last report I spoke of the high-grade ore found on this level, and to date we have continued in ore with the grade running slightly lower, but with the metal more evenly distributed throughout the deposit. There remains now only 23 ft. to be driven to reach the objective point, and from this point a raise of 38 ft. will give connection with the bottom of the 750 winze. The 100 drift at the Castling Copper continues in ore of a high grade, and is now 180 ft. from the shaft, the drift having been in ore for all of that distance. Daily samples during the week have given assays from 8 to 47.7% copper. This ore lies between the limestone and the intrusive, and is following along the base of the limestone hill, where surface conditions are much more favorable for large and rich bodies of copper than they have been in the country recently passed through. These surface conditions indicate that the ore will continue clear around the hill to the Amalgamated shaft on the southern side. This deposit promises fair to outstrip, both in quantity and quality, anything previously found on the property."

NYE COUNTY

A new vein of high-grade ore was recently found on the 950-ft. level of the North Star mine, but was subsequently cut off by a fault. A raise is being made to connect with an intermediate level of the Martha, after which this vein, which is the Martha vein in North Star ground, will be followed. The purpose of the raise was to get the east extension of the Martha vein in North Star ground and the fault raised on was the hanging wall of the same fault against which the Martha vein cut off practically at the North Star line. The dump continues to produce good ore, some forty tons having been secured to date. On the 1250-ft. level the two cross-cuts show no change and are being continued. On the 1150-ft. level stoping continues on the two blocks of ground underneath the 950-ft. level, in which ore was opened by the two prospect raises several weeks ago. The winze from the 1050 is down 85 ft. and driving east and west has just begun. A vein of low-grade is in the bottom of the winze.

WHITE PINE COUNTY

The report of the Nevada Consolidated Copper Co. for the quarter ended September 30 shows a decline in production and a decrease in the grade of ore being milled. The Company reports for the September 30 quarter a deficit from operations amounting to \$95,157, as against a surplus in the corresponding quarter of 1912 of \$798,136. The creation of this deficit was directly due to a decrease in production of 2,569,904 lb. of copper, as compared with the same quarter in 1912. The production during the quarter was 15,835,563 lb., against 17,928,746 lb. in the quarter ended June 30 last, 14,523,565 lb. in the quarter ended March 31 last, and 18,405,467 lb. in the quarter ended September 30, 1912.

The Nevada Consolidated ore milled during the quarter amounted to 813,513 tons, as compared with 762,880 tons in the previous quarter. Ninety-three per cent of the tonnage was supplied from the pits and 7% from the underground working of the Veteran mine. The grade of ore treated averaged 1.53%, as compared with 1.76% for the previous quarter, and 1.74% copper in the quarter ended September 30, 1912. The cost per pound of copper produced, including Steptoe plant depreciation and all charges except ore extinguishment was 10.09c., as compared with 8.95c. for the second quarter, and 8.33c. for the last fiscal year. The overburden stripped during the quarter amounted to 976,664 cu. yd., at an expense of \$316,898. On account of the character of the ore now being milled, the degree of concentration is less than formerly and consequently the concentrate carries less copper, which increases the cost per pound. Experiments are being conducted to devise a cheaper method of treating the low-grade slime.

NEW MEXICO

GRANT COUNTY

The tonnage of ore treated and the output of copper for the past quarter is the largest that has been recorded by the Chino Copper Co. In the quarterly report to the stockholders it is stated that the total amount of ore milled during the quarter was 507,650 tons; as compared with 492,850 tons, for the previous quarter and 429,750 tons, for the first quarter of 1913. The average percentage of copper contained in the ore treated for the third quarter was 2.23, as against 1.88 for the previous quarter, and 1.91 for the first quarter of 1913. The average extraction for the quarter was 66.98%, corresponding to a recovery of 29.92 lb. of copper per ton of ore milled, as compared with an average extraction for the previous quarter of 64.48%, corresponding to a recovery of 24.33 lb. of copper per ton of ore milled. The average grade of the concentrate produced for this quarter was 14.46% copper, as against 15.72% for the previous quarter. The cost per pound of net copper produced for the quarter, after allowing for smelter deductions and without making any credits for miscellaneous revenues, was 8.41c., as compared with 9.01c. per pound for the previous quarter, and 8.24c. per pound for the first quarter of 1913. At the close of the quarter the total amount of copper on hand and in transit (sold and unsold) was 19,540,748 lb. During the quarter there was removed by the steam-shovels, a total of 1,123,688 cu. yd. of material in place, an

average of 374,563 cu. yd. per month. Of this total amount of material removed, 878,044 cu. yd. was stripping, the remainder being equivalent to 510,185 tons of ore. The results of operations during the first three-quarters of the current year are as follows:

	3rd quar.	2nd quar.	1st quar.
Net proceeds from milling.	\$951,293	\$682,052	\$778,804
Miscellaneous income	43,592	34,705	29,019
Total net profit.....	994,890	716,758	807,823
Dividends	643,875	629,790
Surplus	351,015	86,968

Above earnings are computed on the basis of 15c. per pound for the third quarter.

SOCORRO COUNTY

(Special Correspondence.)—Foundations for the electric hoist and compressor at the Pacific Mines Co. have just been completed and air pipe laid in the mine. The new hoist is directly behind the gasoline hoist and the latter will be kept in position for use in emergencies. The mine shipped 175 tons of ore to custom mill the past week. During the week 35 ft. of development work was done at the

for the second quarter of 1913. The low grade of ore treated was responsible for the comparatively high cost of production. Both plants were in continuous operation throughout the quarter, and exceeded all previous records as to tonnage handled, having averaged a little over 22,000 tons per day for the quarter. During the month of September the plants milled an average of about 24,000 tons per day. During the period there was removed a total of 1,422,284 cu. yd. of capping, as compared with 1,225,343 cu. yd. removed during the second quarter of 1913.

A comparison of this quarter with those of preceding years is as follows:

	1913.	1912.	1911.	1910.
Mill profits....	\$1,819,354	\$2,539,584	\$1,150,524	\$946,028
Rent, etc.	11,857	11,699	13,000	12,211
Nev. Con., divi.	357,188	357,188	375,187	371,730
Net profits...	\$2,206,399	\$2,926,470	\$1,538,711	\$1,329,967
Dividends	1,186,695	1,182,413	1,177,012	1,168,883

Net surplus..\$1,019,704 \$1,744,057 \$361,700 \$161,084

The above earnings are computed on the basis of 15c.

UTAH COPPER COMPANY'S MAGMA MILL.

Deadwood mines and 350 tons of ore milled. Concentrate output was about two tons. Three bars of bullion are reported from the last clean-up. The old shaft of the Socorro Mining & Milling Co., leading to first stopes, has been converted into a waste chute and rock from the present workings is dumped into it. The mill is handling about 180 tons of ore per day. Twenty-seven tons of ore was treated at custom mill of the Oaks Co. during the week, obtained from development work on East End Tunnel group. Winze in tunnel B has been sunk 25 ft. and a drift started on a vein about 4 ft. wide. Contractors are driving a drift on the vein at the Alberta Mining Co. property and have encountered good milling ore. The work of enlarging the station over a winze at the property of the Lincoln Mining & Development Co. for accommodation of a gasoline hoist and compressor has been completed and everything is in readiness for the machinery's installation on its arrival.

Mogollon, November 10.

UTAH

SALT LAKE COUNTY

The report of the Utah Copper Co. for the quarter ended September 30 shows the production to have been the largest recorded in the history of this Company. During the quarter there was treated at both plants a total of 2,035,391 tons of ore, as compared with 1,910,214 tons of ore for the previous quarter. Of this tonnage, the Magna plant milled about 56% and the Arthur plant about 44%. The average grade of the ore was 1.2549% copper, as compared with 1.28% copper for the previous quarter. The average cost per pound of net copper produced during the quarter, after allowing for smelter deductions and without crediting miscellaneous income, was 9.068c., as compared with 8.933c.

per pound for copper at the close of the quarter. No copper due for delivery from the refinery remained unsold.

WASHINGTON

STEVENS COUNTY

(Special Correspondence.)—Shipping ore from Chewelah district has been discontinued for a few days while the roads are being repaired. During the past few weeks shipments have exceeded any ever made from this district. The Copper King has averaged daily shipments of one carload, and the United Copper has shipped as much in concentrate and selected ore. The work on the Copper Cliff adit has progressed to the extent that but 40 ft. of work is necessary to reach the point where the ore vein should be found. E. C. Sears and L. D. Peters are at present making arrangements to do development work on the Iron Cap group of claims on Cottonwood creek southeast of Chewelah. They are erecting winter quarters and a blacksmith-shop. The principal work will be done in the lower adit, which is now in 200 ft., and the owners expect to find the lead within a distance of 25 ft., when they will drive to determine the extent of the orebody. The ore is a copper sulphide, and some good returns have been obtained from samples taken at various stages of development. Sears has sold the Iron Horse claim to the United Copper for \$1000. The property is adjacent to the United Copper and has been explored for the full width by the copper company's adit. The Copper Mountain Mining Co. is planning active development of its mineral holdings in the Quatsino district on Vancouver Island, British Columbia. The properties comprise the Merry Widow group of six claims on Elk mountain and are regarded as among the most promising in the Quatsino

region. Work will be begun soon on a railway line from Port McNeill, and a through line from end to end of the island, running near the properties, is being built. It is believed the mines will have been sufficiently developed to begin shipping by the time the railways are operating.

Spokane, November 15.

COSTA RICA

The report of operations at the Abangarez Gold Fields of Costa Rica, issued on November 7, presents the following figures:

	Month of Sept. 1913.	9 mo. to Sept. 30, 1913.	9 mo. to Sept. 30, 1912.
Ore crushed, tons.....	6,144.00	48,477.00	38,526.00
Tailing leached, tons....	737.80	4,791.20	5,616.90
Slime treated, tons.....	4,953.00	39,789.00	28,123.00
Ext. by amalgamation..	\$9,801.24	\$98,777.09	\$206,668.45
Cyanide extraction.....	46,216.68	325,500.85	285,268.36
Total extraction	\$56,017.92	\$424,277.94	\$491,936.81
Less cost of operation, marketing, and admin- istration (exclusive of betterments)	51,853.19	453,902.99	576,611.81
Profit from operations	\$4,164.01	*\$29,625.05	*\$84,675.00
Betterment expenditures.	3,923.46	61,180.22	187,909.17
*Deficit.			

CANADA

ONTARIO

The Mond Nickel Co. recently purchased the Levack properties, the purchase price being \$750,000. This property has an area of 1600 acres and is situated 30 miles west of Sudbury. This property has been under option for some time, and six diamond-drills have been constantly prospecting the orebodies. It is learned that they have over 2,000,000 tons of ore developed. The sum of \$40,000 was paid by the Mond company when the option was granted, and under the terms of the agreement the balance and final payment is due in December unless amended arrangements are entered into. The Levack properties were discovered and located about the year 1882, by one of the present owners, James Stobie.

MEXICO

MICHOACAN

The shaft which is being sunk on the property of the Cia. Minera de San Vidal y Anexas has now reached the fourth level, and cross-cutting to the vein has been started. This Company was organized about a year ago with Charles Hoyle, general manager for the Esperanza Mining Co., as president.

SONORA

(Special Correspondence).—Mineral exports through the customs house at Agua Prieta during the month of October was valued at \$3,755,800, being an increase of \$450,700 over the preceding month. Considering the condition of the country, the increase in exports of mineral is nothing short of remarkable, and the amount of last month is the largest ever shipped through that port in any one month heretofore. The October gross smelter production of the Cananea smelter will be a little over 7,000,000 lb. Of that amount the output from the Cananea company's own ores will be in the neighborhood of 2,800,000 lb. Over 40 ft. of fairly high-grade ore has been opened on the 300-ft. level of the Palo Seco mine of the Moctezuma-Arízpe (Mexican Metals) company, situated about 18 miles southeast of Cananea. La Dura mine, situated in the Yaqui district, and owned by the Mines Company of America, has been shut down, the first intermission in operations for over thirty years. The employees have all been dismissed and the Americans returned to the States. An El Paso group of financiers have organized a company for the purpose of taking over the Monte Cristo property, owned by C. C. Soto and situated in the Moctezuma district. The property is considered a rich one, and during the past ten years over \$100,000 worth of mineral has been shipped.

Nogales, November 15.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

O. C. PERRY is at Oroville.

CHARLES JANIN is in London.

F. H. MORLEY is in San Francisco.

F. LYNWOOD GARRISON is on his way to California.

H. W. MACFARREN has been at Jackson, California.

HAROLD C. COOKE is in the city from British Columbia.

FRANCIS J. DENNIS has gone to London on professional business.

GEORGE E. FARISH has returned to New York from British Columbia.

CHARLES E. VAN BARNEVELD has returned to San Francisco from the East.

M. W. VON BERNEWITZ has returned from his visit to the dredging fields.

J. MOISAN is back from the Philippine Islands and will return to Virginia.

F. W. NOBS, manager at the Leonesa mine, Matagalpa, Nicaragua, is visiting San Francisco.

C. L. LARSON, who has been with the Chicksan Mining Co., has returned to the United States.

H. KENVON BURCH, chief engineer for the Inspiration Copper Co., is at Greenwich, Connecticut.

AUGUSTUS D. COX has gone from Manhattan to Tonopah, where he will be for the next three months.

J. D. HUBBARD and J. SPIERS were inspecting a drift mine near Chico, Butte county, California, last week.

R. Y. WILLIAMS has resigned from the U. S. Bureau of Mines to organize the Miners Institutes for the University of Illinois.

CHARLES HELMAN, of the El Oro Gold Dredging Co., has returned to Oroville, after several months in Montana and other states.

FAYETTE A. JONES, president of the New Mexico State School of Mines, is examining mining property in Elko district, Nevada.

ARTHUR W. BURGREN, of the A. S. & R. Co., Matehuala, San Luis Potosi, Mexico, is in San Francisco, his address being 443 Holbrook building.

H. N. BOWEN will leave Carson City, Nevada, on December 1, to take charge of the mines of the Continental Copper M. & S. Co., at Hill City, South Dakota.

G. M. COLVOCORESSES has returned to New York from professional work in the West. He is now consulting engineer to the Consolidated Arizona Smelting Company.

WEBB SMITH, manager for the Kennedy Mining Co., Jackson, narrowly escaped a fatal accident in a skip in the shaft early last week, and has been laid up on account of the bad shaking received.

C. E. GRUNSKY, Jr., formerly superintendent for the Standard Con. M. Co., has joined the staff of the American Engineering Corporation at San Francisco, and will take charge of the mining work.

L. F. S. HOLLAND has returned to Telluride, Colorado, after examining mines in Beaver county, Utah, and Park county, Colorado. He is arranging to make his headquarters at Los Angeles during the coming winter.

WILLIAM S. MANN, formerly metallurgist for the New York & Honduras Rosario Mining Co., is erecting an all-sliming cyanide mill for the Socorro Gold & Silver Mines, Ltd., Valle de Angeles, Honduras, Central America.

H. W. HARDINGE has gone on an extended tour through the Northwest, including British Columbia, to inspect the recent large installations of Hardinge mills in that district. He expects to be gone between six and eight weeks.

W. R. NOBS, who died at Maracaibo, Colombia, September 14, was a Stanford graduate who was formerly connected with the K. T. & O. Co. at Coalinga. He was in Colombia for the Caribbean Petroleum Co. and became infected with tetanus while quinine was being administered to him for fever.

The Metal Markets

LOCAL METAL PRICES

San Francisco, November 20.

Antimony..... 10-10½c	Quicksilver (flask).....\$39
Electrolytic copper..... 17½-17¾c	Tin..... 44-45½c
Pig lead..... 4 60-5.55c	Spelter..... 7-7½c

Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.

EASTERN METAL MARKETS.

(By wire from New York.)

NEW YORK, November 20.—The copper market is weaker, consumers are holding off, and but little buying is reported. Yesterday closed with electrolytic at 15.25 to 15.50 and Lake at 16.50. The London market is quiet with spot at £67 7s.6d. and futures at £66 17s.6d. At Boston there was noticed a slight reduction in the official quotations of copper, this, however, was unimportant. The lead and spelter market remain dull.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending

Samuel Montagu & Co.'s report of November 6 contains the following regarding the position of silver: The tone of the market is somewhat better. Speculative sales from India and from China have gradually come to an end. Coincident with the reduction in China sales, a certain amount of China buying set in, which checked the fall in rates. Yesterday the steadiness of the market became obvious, and China sales ceased, whereupon some 'bears' felt inclined to cover, and the price rose to 27½d. for both deliveries. Although the improvement may continue, it is not possible to be certain as to the future, for speculation in China exchange may produce unexpectedly a resumption of China sales of silver. The stock in Bombay is now much smaller than it has been for years. This week it has fallen from £300,000 to £245,000; the off-take is about 55 bars per day.

Shanghai reports a stock of £6,225,000, compared with £6,250,000 last week. It appears to be well known that between £1,500,000 and £2,000,000 of this stock is deposited with the banks, foreign and native, mainly with a view to safe custody. A reabsorption of this amount for trade purposes would reduce the present stock to about £4,225,000, at which it would not look quite so unwieldy. Now that unrest in China has simmered down, there is a possibility of such a reduction taking place. An Indian currency return showed an increase of 10 lacs under the denomination of rupees, of 120 lacs under that of silver under coinage, and of 24 lacs of sovereigns under that of the standard reserve in India. There was a decrease of 60 lacs under the denomination of gold in India.

ZINC

Zinc is quoted as spelter, standard Western brands St. Louis delivery, in cents per pound.

Rudolf Wolff Kreuger & Co., in their weekly spelter report, write: "The spelter market has been interesting. The low prices attracted the demand from consumers which had been anticipated in a previous report, and this has resulted in values being gradually stiffened until November is bid for at £20 12s. 6d. There has been more trading in galvanized iron, and it is to be hoped that the more normal prices now ruling for copper may stimulate the brass trade. The outlook for the future is excellent, but in the

meanwhile rather heavy stocks are weighing upon the market. The stocks in the hands of the syndicate have been considerably reduced. The syndicate price in England is £21 5s. for November and £21 7s. 6d. for December, but in France and Belgium a considerable reduction was made which has since been followed by a slight advance of 1s. 6d. On the whole, the outlook and position is considerably improved, in spite of the surrounding depression in other metals. The only unfavorable feature from a 'bull' point of view is the heavy premium on forward spelter, which even now stands at 16s. 3d. above the price of spot metal.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

The German consumption of foreign copper for the months January to September, 1913, according to L. Vogelstein & Co., was as follows:

	Tons.
Imports of copper	174,300
Exports of copper	7,327

Consumption of copper 166,973

The consumption for the same period in 1912 was 153,374 tons. Of the above quantity, 150,564 tons was imported from the United States.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

FULLER'S EARTH has been recently studied by the United States Bureau of Mines, which finds that there are American deposits even better suited for use in refining edible oils than those abroad. Previously local material, while used in the petroleum industry, had been considered unsuitable for bleaching edible oils. Fuller's earth is a regular article of commerce that may be sold through jobbers. According to the U. S. Geological Survey, production in 1912 amounted to 32,715 tons, worth \$9.34 per ton at the mine. Unground earth costs the refiner about \$14.50 per ton and ground earth \$16.

ACCORDING to A. H. Brooks, the placer production of gold in Alaska for 1912 was less than for 1911, but the production of lode gold was greater than ever before. The total mineral production for 1912 was \$22,285,800, as against \$20,505,601 for 1911.

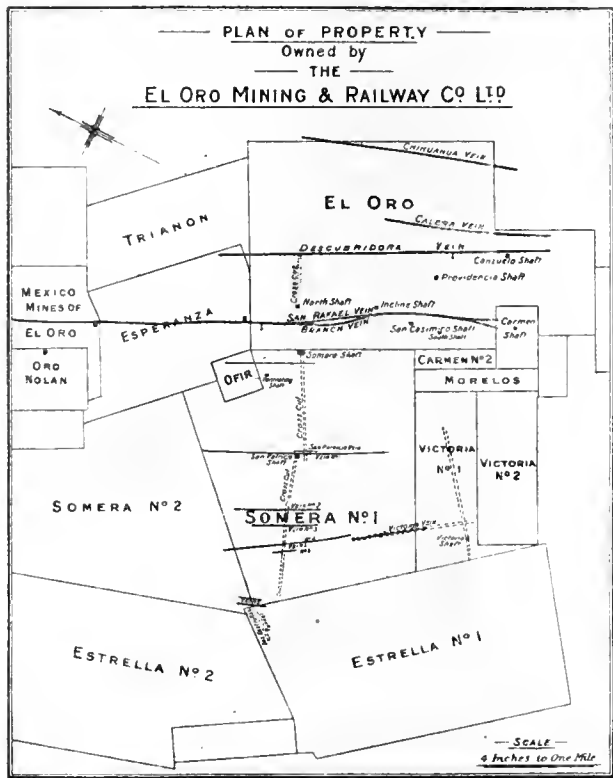

DURING the month of August the sum of £33,375 was paid in dividends by Western Australian gold-mining companies.

Company Reports

EL ORO MINING & RAILWAY CO., LTD.

The El Oro Mining & Railway Co., Ltd., operates in Mexico, and the report covers the year ended June 30, 1913. The principal results may be summarized as follows:

		Gold content
Ore reserves.	Tons.	per ton.
Northern orebody	109,896	\$ 5.70
Southern orebody	120,465	4.59
Lower levels	98,526	18.16
San Patricio	119,166	5.58
Total	448,053	\$ 8.11

In addition to the above gold content, the ore averages 3 oz. silver per ton.

Ore mined for these veins from 86 to 1450-ft. depth, tons	253,413
Ore milled, tons	253,434
Sand tailing treated, tons	180,274
Sand remaining for re-treatment, tons	198,005
Recovery from all sources, per cent.....	88.39
Bullion realization	\$2,188,724
Working expenses	1,490,382
Profit from railway department	117,983
Interest and sundry revenue	40,800
Net profit realized	768,000
Dividend No. 24 for the period	274,000
Dividend No. 25 for current year	274,000
Carried forward	418,000
Total dividends to date	8,563,000

The report of the general manager, A. F. Main, contains full details of the San Rafael vein at the upper levels; the San Rafael and West veins on the lower levels; the Ofir claim in which is blocked out 43,375 tons of ore averaging \$23.12 gold and 8 oz. silver per ton, and a total profit in sight of \$1,000,348; the western veins in the Somera claim; the Chihuahua vein, and the southern extension of the San Rafael vein in the Carmen mine. Generally speaking, the ore reserves in every part of the property show an increase as compared with a year ago, even without considering the Ofir claim, which, in itself, is proving of the greatest importance. A 500-gal. per minute electric pump was installed on the 1600-ft. level, and a large fan was erected at the mouth of the ventilating shaft to force fresh

air to the lower levels. The mill of El Oro Mining & Railway Co. treated 22,940 tons of ore and 13,760 tons of old tailing during September, yielding \$177,550. The total profit was \$64,140, including \$8500 from the railway.

KALGURLI GOLD MINES, LTD.

This Company operates a very profitable mine at Kalgurli, and the report of the general manager, R. S. Black, covers the year ended July 31, 1913. From the 100 to the 1850-ft. level, 128,415 tons of ore was mined, and 15,170 tons of \$7.50 ore was broken and is in the shrinkage stopes. Development covered 3759 ft., also 3546 ft. of sample holes and 369 ft. of diamond-drilling. The Kalgurli mine is noted for its short, wide, and irregular ore-shoots. The ore reserves are approximately 250,000 tons. On the 100-ft. level, driving opened ore 15 by 80 ft. worth \$6 per ton; at 300 ft., the ore was 15 by 45 ft., worth \$17; at 850 ft., the main east shoot showed an area of 25 by 75 ft., averaging \$9; work at 1000 ft. was not favorable; a winze sunk on the east lode at 1250 ft. passed through 6 ft. of \$30, 21 ft. of \$20, and 14 ft. of \$14 ore; between the 1250 and 1350-ft. levels, a shoot 28 by 90 ft., worth \$17, is being mined; the 1650-ft. shoots are entirely satisfactory; while the 1850-ft. level has been disappointing. A geological examination of the lower levels of the mine was made by Malcolm Maclaren, who states that the eastern orebodies passed finally out of the favorable quartz-dolerite at 1650 ft., and the western orebodies a little below the 1750-ft. level. At 1850 ft. no quartz-dolerite whatever has been disclosed, and this level lies entirely in calc-schist. Exploration on the two bottom levels has been fairly comprehensive, and it would seem that it is unsound business to sink deeper in the Kalgurli mine.

The mill treated 128,415 tons of ore, yielding \$1,224,000, with 93.17% recovery. Mining cost \$1.90 and treatment \$2.90 per ton.

MOUNT BISCHOFF TIN MINING COMPANY

This is one of the most important lode-tin properties in the world, and is situated in the West Coast district of Tasmania. The report covers the half-year ended June 30, 1913, and may be tabulated as follows:

Ore mined, tons	116,728
Ore milled, tons (difference being sorted)	116,063
Tin concentrate recovered, tons	580
Smelter operations:	
Concentrate smelted, tons (588 from mill and 1056 from other mines)	1,644
Metallic tin produced, tons (372 + 745)	1,117
Assay of metals, tin per cent.....	99.88
Recovery of tin per ton of ore, pounds.....	7.76
Costs per ton of ore treated:	
Mining	\$0.69
Prospecting and development	0.05
Aerial tramway	0.03
Milling	0.30
Electric power	0.01
Assaying, surveying, etc.....	0.02
Water-supply	0.03
Administration	0.05
Total	\$1.18
Revenue	\$375,000
Net profit	163,000
Dividend	173,000
Carried forward	494,000
Surplus of assets over liabilities	240,000
Capital	119,200

BROKEN HILL SOUTH SILVER MINING COMPANY

This Company operates an important silver-lead-zinc property at Broken Hill, New South Wales, and the report under review covers the six months ended June 30, 1913. The general manager, W. E. Wainwright, gives the following information. The effect of the fall in metal prices is reflected in the accounts, and unfortunately the price of zinc has still further receded since the close of the half-year. Lead, however, remains firm. During the half-year

two dividends have been paid, amounting to \$768,000, while \$27,400 has been written off plant account, and the balance of profit and loss account, \$528,000, has been carried forward. The liquid assets amount to \$864,000. Work at the mine has proceeded regularly and satisfactorily, except that during the month of April a serious stoppage for three weeks occurred owing to the closing of railway communication on account of the strike of the employees of the Silverton Tramway Co., which considerably reduced the output and the earnings of the period under review. The policy of exploring the southern portion of the property and of shaft-sinking has been continued, and with satisfactory results. The average weekly tonnage of ore treated amounted to 5836 tons. Tailing delivered to the Amalgamated Zinc and Zinc Corporation flotation plants was 129,907 and 39,270 tons, respectively. Experiments being made on the accumulated slime, about 330,000 tons, have been continued with good results, and something definite will soon be decided upon. Other details may be summarized as follows:

Development, feet	5,522
Filling, cubic yards	53,726
Ore mined from 425 to 1170-ft. levels, inclusive, tons	151,836
Deepest workings, No. 4 shaft, feet	1,202
Metal contents of ore milled:	
Lead, per cent	14.4
Zinc, per cent	13.7
Silver, ounces	6.5
Concentrate produced, tons	24,417
Lead content, tons	17,141
Zinc content, tons	1,632
Silver, ounces	554,266
Zincy tailing produced, tons	109,098
Total costs per ton of ore	\$5.44
Value of metal production	\$ 1,440,000
Water consumption, gallons	29,914,200
Rainfall, inches	1.6

SIAMESE TIN SYNDICATE, LIMITED.

The company was registered in 1906 to acquire and work tin deposits in Siam and elsewhere. An alluvial tin area of 635 acres at Ngow, Renong district, is being worked. Two additional dredges of double the capacity of No. 1 were expected to begin work during the latter part of 1913. Application has been made for a lease of 300 acres bearing alluvial tin, at Bangrin, about four miles from the Ngow area. Drilling has been done. The estimated life of the property is eleven years. The Company also has a coconut plantation and a trading business; a small revenue is also obtained from two properties which are being worked on tribute. The capital is £120,000 in 120,000 shares of £1 each, all the shares being issued and fully paid, including 30,000 credited as fully paid. From sales of ore from tributaries and sundry income from properties on lease £7,518 was realized. The expenses of dredge No. 1 were £23,582. The year resulted in a net profit for the company of £40,822. Two interim dividends of 10% each have already been paid during the year, leaving a balance of £16,822, out of which the directors recommend the payment of a final dividend of 10%, carrying forward £4,822.

THE TANALYK CORPORATION, LTD.

This Company, which has a capitalization of £300,000 in £1 shares, was organized in April 1912, and holds all the shares of the South Urals Mining & Smelting Co., Ltd. Its land holdings amount to 9500 acres in the Orsk district of the Orenburg government, together with timber rights on 300,000 acres of forest. It is developing copper, manganese, and magnesite deposits. The first report covers the period from April 15, 1912, to January 13, 1913. The property is just emerging from the development stage, but already 70,000 tons of ore assaying 2.9% copper, \$7.40 gold, and 7½ oz. silver are definitely in reserve, and a large smelting plant is being erected. The large amount of capital which is being expended for the development of this property is evidence of confidence in its future, and the results of this venture will be awaited with interest.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

LAND CONTAINING GRANITE DEPOSITS IS MINERAL LAND

Land containing deposits of granite of a quality valuable for building purposes and in quantity sufficient and location suitable for marketing for such purposes, is mineral land and not subject to forest lieu selection under the Act of June 4, 1897.

Merkley John v. Hyde & Co., 42 Land Decisions, 144. April 30, 1913.

PATENT IMPROVEMENTS—REPAIRS TO TUNNELS

Where a tunnel has been driven for the development of certain claims which were afterward abandoned and subsequently relocated, the relocators, upon application for patent, cannot accredit expenditures made for the repair of said tunnel as a common improvement counting toward the requirement for patent purposes, when it does not appear that they extended the tunnel or in any way added to its original value for development purposes.

Austin Manhattan Consolidated Mining Co., 42 Land Decisions, 75. March 14, 1913.

ADVERSE CLAIMS—VERIFICATION

An adverse claim by a corporation, filed under Section 2326, Revised Statutes, relating to the contest of patent applications, may be verified by its executive officer outside of the land district where the claim involved is situated, but at the principal place of business of the corporation. Under such circumstances, it is the act of the corporation itself and within the provisions of the statute permitting verifications by claimants in person outside of the land district in which the claims are situated.

Frank Hough Mining Co. v. Empire Prince Mining Co., 42 Land Decisions, 99. April 24, 1913.

AMENDED LOCATION—NOT TO PREJUDICE OTHERS

Where a locator in 1900 located a quartz claim and in marking his boundaries paced the distances and estimated the angles at the corners, after a lapse of more than ten years, during which one of his corners became obliterated (if it ever existed), and other parties located adjoining ground and made a discovery thereon, the first locator will not be permitted to amend his location so as to include their discovery point under the pretense of correcting his survey, where a substantial doubt exists as to the location of the original boundary line between the two claims. Such a correction in the boundary line cannot be allowed after a lapse of considerable time where the rights of others have intervened.

Gobert v. Butterfield, 17 California Appellate Decisions, 367. October 1, 1913.

OIL PLACERS—POSSESSION PRIOR TO DISCOVERY

A tract of oil land in Ventura county, California, was located as the 'Rawley' placer in 1883 and as the 'Schley' placer in 1910. The earlier locators had made no discovery, done no work, and were not in possession at the time the later location was made. Their claim of right was based upon the theory that the wells which they were drilling on adjoining claims "tended to develop" the oil-bearing character of the Rawley claim. The 'Schley' locators leased their claim, and the lessee went into possession, commenced drilling operations, and continued to work with due diligence, although at the time of commencing this action no discovery had been made. Held, that the locators of the Schley claim, being in actual possession through their lessee and prosecuting discovery work with due diligence, had the better right and sufficient grounds to maintain a quiet title suit against the 'Rawley' locators. The statute permitting work done on one claim to inure to the benefit of other claims which such work tends to develop, applies only to assessment work and does not apply to claims upon which no discovery has been made.

S. R. Smith v. Union Oil Co., 46 California Decisions, 287. September 29, 1913.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

ARKANSAS has two mountains which, according to a chart published by the United States Geological Survey, are each 2800 ft. in height, Blue mountain and Magazine mountain. The lowest point in the state is 55 ft. above sea-level.

SILICA BRICK are specially made brick used for furnace linings and also in tube-mills. They sell at a much higher price than ordinary building brick, because of the skill and care necessary in their manufacture, and the relatively limited market.

TODE STONE is a volcanic amygdaloidal rock, generally decomposed, occurring as sheets of contemporaneous lava in the Carboniferous limestone of Derbyshire, England. The term is an old one and means 'dead stone,' referring to the barrenness of the rock as regards mineral veins.

CARNOTITE is mined in southwestern Colorado and shipped to Pittsburgh, where the Standard Chemical Co. is producing radium at the rate of about one gram per month. Production began last May, and officers of the Company estimate that the supply of rock available will yield a total of six pounds of radium.

CAM-SHAFTS for a battery of 1000-lb. stamps will, if made of hammered iron or so-called mild steel, be not less than $5\frac{7}{8}$ in. diameter, though some builders make them $5\frac{1}{2}$ in. for 5-stamp units. For such units the length would be 8 ft. 2 in., assuming 12-in. posts 5 ft. apart. A $5\frac{7}{8}$ -in. shaft of this length weighs 760 pounds.

ROCK PHOSPHATE, according to E. H. Sellards, state geologist, was produced in Florida in 1910 to the amount of 392,088 tons. Total shipments exceeded this, 461,353 tons having been sent abroad and 18,745 tons shipped to domestic points. The total production of pebble rock was 2,029,797 tons, of which 606,110 tons was shipped abroad.

NICKEL is not mined as such in the United States. The output of nickel from domestic ores is merely a by-product from electrolytes of the copper refineries. Salts and metal equivalent to 328 short tons of metallic nickel were saved in domestic refineries in 1912 from both foreign and domestic ores. Nickel ore 'imported for consumption' is mostly from the Canadian deposits.

ANTHRACITE, according to E. W. Parker, is mined at an average cost of \$1.86 per ton and sold for \$2.06; this margin of 20c., however, makes no allowance for interest or depreciation, and in fact probably no great industry is operated on so narrow a margin as coal-mining in the United States. Where prices are high, this is due to transportation and delivery charges rather than to mining costs.

MICARTA is a new material which has been developed by the Westinghouse company to take the place of hard fibre, glass, porcelain, hard rubber, built-up mica, pressboard, rawhide, and other materials used for commutator bushings, brush-holder insulation, noiseless gear blanks, and similar uses. It is insoluble in practically all ordinary solvents, indifferent to ozone, non-hydroscopic, and impervious to moisture.

PROSPECTORS should not only seek to determine the value of the mineral or ore which they have discovered, but they should also endeavor to determine the quantity. Needless to say, a small pocket of ore, although it may be quite rich, often costs more to realize upon than it is worth. On the other hand, a large deposit, even though it be quite low in value per ton, is often an attractive proposition to a capitalist. In the case of most metalliferous mines 'quantity of ore' can only be determined by extensive workings and the expenditure of time and money; but with non-

metallic minerals often a detailed study of the deposit will give some information as to the quantity available.

SECTIONALIZED machinery is necessary where the material must be transported by mule-back. The carrying capacity of an ordinary mule is about 300 lb., but the possible weight limit should, as far as possible, be placed at half this, since it is simpler and better to balance the load in two parts on the mule's side, than to attempt to mount it on his back. The extra heavy pieces will cost dearly before they reach their destination.

GOLD AND SILVER mines to a total of 5699 were listed as producing in 1912, in the United States, excluding the Philippine Islands and Porto Rico. Of the total 3553 were deep or quartz mines, and 2146 were placer. The largest number of mines in any one state was 1041, in California. The actual number producing in any one year varies considerably, but ranges between 5190 in 1907 and 5699 in 1911. These figures are from the statistical records of the Geological Survey.

BREAKAGES in cam-shafts are due primarily to fatigue of metal, the fibrous structure of the steel being destroyed by the constant pounding, and the material crystallizing. No way has been found to prevent cam-shaft breakages entirely. Mounting 10 stamps on a shaft rather than 5 makes a better distribution of torsional strains, but throws more stamps out of service when breakage does occur. Good material, good workmanship, and good foundations will minimize but not prevent the breakage.

AN important consideration affecting the efficiency of operation of a wet-crushing mill lies in the provision of an adequate water-supply, and due attention should be paid to this point in all preliminary estimates. Heavy running expenses, both in treatment methods and residue disposal can be reduced, and in some instances almost eliminated from the cost of operation by ample water provision. Even a heavy initial outlay for water-supply is invariably fully justified by subsequent economy of practice.

BRIQUETTING of slime, or 'slum' as it is locally called, is accomplished at Anaconda by mixing with water in an ordinary pug mill such as is used in making brick by the stiff mud process. The briquetted material is delivered in the form of a horizontally moving clay bar traveling on a flat belt. Formerly it was cut into regular bricks by means of the usual wire wheel, but since the only object of the process is to make the material stick together long enough to become buried in the furnace, even this was abandoned as an unnecessary refinement. The bar is now broken irregularly as it passes from the original belt to one which travels in the same direction at a more rapid rate; the usual form of delivery in clay-working plants. The whole equipment is simple, cheap, and effective.

SILICA is used for many different purposes and the total sold amounts to over 65,000,000 tons per year. The total value, however, is small, approximately \$21,000,000, according to the United States Geological Survey. The powdered silica quoted monthly on another page of the *Mining and Scientific Press* is a prepared product and a large part of the price is due to the cost of selection and preparation. The crude material is abundant and of little value. To make it merchantable, a finely divided silica of absolutely uniform grade and composition must be offered. The largest part of the miscellaneous market is supplied from Ottawa, Illinois, where in the St. Peter sandstone there is an enormous quantity of unusually pure and unusually uniform sand, available for the digging and grading. There are large concerns engaged in preparing and marketing this sand, and anyone wishing to compete would need to study the business as a manufacturing industry rather than a mining enterprise. An excellent article upon glass sand and other sands, written by E. F. Burchard, appears in the 'Mineral Resources' for 1911. It may be obtained from the Director of the U. S. Geological Survey at Washington.

MIDDLE AND UPPER DEVONIAN. Text. By Charles S. Prosser, Edward M. Kindle, and Charles K. Swartz. P. 720. Ill., maps, index.

DEVONIAN. Plates 73.

These three volumes deal with the systematic geology and paleontology of Maryland. The first is devoted to a consideration of the lower Devonian deposits and their contained faunas. The record is the combined work of a number of individuals, most of whom are specialists in their own particular field of research. In the compiling of this work the Maryland Survey has had the cooperation of the U. S. Geological Survey. The second is devoted to a consideration of the Middle and Upper Devonian deposits and their contained fauna. As in the previous volume, this work comprises the combined efforts of a number of individuals. There is also a volume of plates accompanying these works which illustrate the paleontology of the Lower Devonian of Maryland. The volumes are indexed and fully illustrated.

Mechanical Shoveling Underground

Many attempts have been made to perfect a machine which would do the hard and expensive work of shoveling broken rock underground. At the surface, steam-shovels, grab-buckets, and similar devices are available, and to a limited extent the smaller 'steam-shovels', usually driven by compressed air or electricity, are in use in the mines. Ordinarily they can not be used because the quarters are too cramped. This is especially true in tunnel work where speed is all important and where, accordingly, mechanical shoveling would be especially important. Every experienced tunnel driver realizes that the essential problem is how to get rid of the broken rock in the shortest possible time. In coal mines and in all properties where loading is done from the floor, the cost of shoveling is serious, and any relief will be welcome. In driving one of the long adits in the Coeur d'Alene region, Thomas Cox used a mechanical conveyor for loading cars and greatly ex-

is reported to be loading over 5000 tons per month. The construction and method of operation are shown in the accompanying illustration.

Commercial Paragraphs

The BURY COMPRESSOR Co., Bury, Pennsylvania, is just starting the erection of an addition to its plant, extending the main plant 100 ft. This is necessary on account of increase in business.

The KEYSTONE DRILLER Co. was awarded the contract August 22 for its largest Downie double stroke pump for the city of Naperville, Illinois; capacity 350 gal. per minute, 300-ft. head; pump to be direct connected to motor.

The WESTERN ELECTRIC Co. reports that it has been given a contract for mine telephones by the Oklahoma Coal Operators Association. Eight hundred of the Company's standard No. 1336 type mine telephones, with complete

MYERS-WHALEY SHOVELING MACHINE.

pedited his work. Even here, however, it was necessary to have men shovel from the floor to the conveyor, though there was a great gain in that the broken rock was raised inches rather than feet.

The Myers-Whaley Co. is now manufacturing a mechanical shoveler, which is shown in the accompanying picture. This machine is now in use in coal, iron, salt, and lead mines, and in contracting work on the Catskill aqueduct. It may be driven by electricity, compressed air, or steam, is self propelling, requires but one operator, and permits using the conveyor as a preliminary picking belt. It is built in several sizes weighing from 6000 to 16,000 lb., and is said to require but 7½ to 12 hp. The capacity is given at 1750 lb. coal or one-half cubic yard of rock per minute for the smallest, No. 2 machine, and 2875 lb. coal or 0.82 yd. rock for the No. 4 or largest. A No. 4 machine working in a lead mine at Flat River, Missouri, is reported to be averaging one ton per minute on the day shift and a little less at night. It has been in use since December 4, 1912. Its output in April for 22 days was 6626 tons, and in May, 24 days, 6612 tons. During the week from April 25 to May 1, inclusive, it loaded 1958 tons, or an average of 163 tons per shift. The machine is run entirely by one man. Two men are used to break rock too big to go through the mine chutes, though the machine itself will handle lumps weighing 800 to 1000 lb. and of large dimensions. One man is used to couple cars and clean up the tracks. Total crew, four men.

In a salt mine at Retsof, New York, another machine

wiring and installing material, are included in this order, which is the largest ever placed at any one time for such equipment.

The TRUAX MANUFACTURING Co., for many years makers of small cars for mining and industrial purposes, announces its removal to new and larger quarters at Eleventh and Wazee streets, Denver. Hyatt flexible roller bearings and special car and cart construction are keeping this well known concern busy.

The S. FLORY Mfg. Co., Bangor, Pennsylvania, reports that since the fire sustained some months ago, temporary buildings have been erected and equipped with improved high-grade machinery, and it is ready to take care of orders as in the past. The business will be continued in Bangor and the permanent building erected as early as possible.

The HARDINGE CONICAL MILL Co. reports that it has been awarded a contract for grinding machinery by the National Copper Co., Wallace, Idaho. This includes machinery for preliminary granular fine crushing as well as the final re-grinding. Also that the ATRASAR COPPER Co., of Russia, has just placed an order through the London office of the Hardinge Conical Mill Co. for six of the largest size Hardinge mills to be equipped with Hardinge type manganese steel liners. The Britannia Mining & Smelting Co., which is at present installing a flotation process for the separation of ore, has decided to increase its capacity, and has ordered more Hardinge mill equipment, bringing the present installation up to nine mills.

ECUADOR has authorized a loan of £2,000,000 for the purpose of sanitation at Guayaquil, and a representative of J. G. White & Company has been called from London to arrange terms for the contract.

OWING to failure of certain drawings to arrive from London in time for use, publication of the remaining parts of Mr. C. B. Horwood's series of articles on the Rand bankets has been necessarily suspended for a week or two.

BUJUN is a Japanese variant of Fushun, the better known name for the coal mines near Mukden opened by the Russians and now operated by the South Manchurian Railroad Company, and described on another page by Mr. Reiji Kanda.

THE barometer of the Mexican situation seems to be embodied in the person of Victoriano Huerta, and the clear, cloudy, threatening, and storm readings as daily recorded in press bulletins present a true log not only of the status of diplomatic relations, but also the daily consumption of fermented grape juice by Don Victoriano.

AWARD of the gold medal of the Mining and Metallurgical Society of America to Mr. H. C. Hoover and his wife, Mrs. Lou C. Hoover, for their "distinguished contributions to the literature of mining" is announced at New York. This is a pleasing and appropriate recognition of the magnificent gift to the profession embodied in their translation and editing of Agricola's 'De Re Metallica.'

ONE of the peculiar situations that has developed as a result of the present conditions in Mexico is the fact that coin silver as such, at the present rate of exchange, is of less value than the market price of bar silver. In consequence of this state of affairs, Mexican coin is being melted into bars for export, and a decided shortage is reported. To put a stop to this practice an executive decree has been issued providing severe punishment for those guilty of melting coin. The situation recalls that of a number of years ago when the melting of Mexican silver coin and parting it for the gold content proved a profitable industry. With the silver coin being exported as bullion, and most of the new currency being in the form of I. O. U.'s, forced on the Mexican public by revolutionary leaders, the Mexican currency question is becoming interesting.

DECIMALS are generally looked upon as affording the best means for scientific expression of numerals and it is, therefore, a pleasure to note that a real decimalist has been employed to compute for the United States Geological Survey the value of gold for the year 1912. The factor used was \$20.671834627323 per fine ounce. The millionth part of a mill would have been fairly accurate from a dollar and cents standpoint, but carrying the figure to three decimal places further leaves no doubt as to the actual value of gold for that year.

GEOLOGISTS will find much of interest at the twenty-sixth annual meeting of the Geological Society of America which will be held at Princeton, New Jersey, from December 30 to January 1, inclusive. The sessions of the society will be held in Guyot hall of Princeton University, where the accommodations are so ample that the Council has decided to continue the plans adopted for the management of last winter's meeting. The morning sessions will be devoted to papers on subjects of general interest; the noon recess will be long, in order to give time for social intercourse, group discussions, and the examination of exhibits. The afternoon sessions will be somewhat short and will be devoted to papers of less general scope. The program provided is a most attractive one and a hearty welcome is assured to those who make the journey to 'Old Nassau' for this meeting.

AT A RECENT congress of 'scientists' at Halle, for the purpose of testing the efficacy of the divining rod in the discovery of underground water and mineral deposits, so much enthusiasm was stirred up by the forked stick that it was decided to organize an international association to investigate its prowess. A report of the proceedings of this congress states that experiments conducted by 'experts' present resulted in the discovery of three potash veins, coal deposits, water courses, and a leak in the city water main: but inquiry addressed to one of the professors in the University of Berlin brings the information that while in Germany there is a school of technologists who swear by the divining rod, "when one asks for visible results, he finds nothing new." When our German friends master this lost art it is not improbable that the quest for Captain Kid's treasure and the leak in some of our modern corporations will be greatly expedited.

ENDOWED prospecting is now proposed following the lead of the Empire Mines Company, which owns the only endowed gold mine of which we know, and the Canadian Mining & Exploration Company, which has practically endowed a staff for examining mines with a view to purchase. The latest proposal comes from Douglas, Alaska, where the Northwestern Development & Mining Company has been organized to grubstake a couple of prospectors. The peculiar feature of the plans of this Company is that it is proposed to invest half the capital stock in some commercial business, preferably a local store, from the returns on which 4 per cent dividends are to be paid, the surplus going into

the prospecting fund. This is one way to reestablish the old relation between local merchants and prospectors, but will run counter to the human prejudice in favor of each controlling his own re-investments. Aside from that, neither prospecting nor country stores have as yet proved good fields for investment of company capital in small units, since the personal element is so large a factor in the success of each. Such a plan, while opening the way to unusual profits as well as losses, does not seem to offer much hope of stabilizing prospecting, the matter of chief concern.

AS noted last week, the committee of Colorado editors who have been investigating the strike in the coalfields and before whom appeared representatives of the operators, the strikers, and the Governor, decided that there was no justification for a further continuance of the strike. The committee found in favor of the strikers on four points and of the operators on two. It was held that the men are entitled to an eight-hour day, to checkweighmen, to the right to trade at any store, and to the strict enforcement of all the mining laws. It was further held that, while recognition of the union must be optional with the operators, the right of any man to belong to a union without prejudice or discrimination is guaranteed by the laws of Colorado and full support was pledged to the Governor in enforcing all the laws. The advance in wages asked for was refused on the basis of the showing of the operators that the average wage paid was more than a 'living wage' and that it compared favorably with that in other Colorado industries. Since announcement of the conclusions of the editors, the operators have given formal consent to the award. The action of the men is awaited with interest. On one point we do not agree with the committee, which held in favor of employment of mine guards. Police work belongs to the state, and mining companies should not be put to the expense of protecting their property; neither should they have the privilege of maintaining what amounts to private armies. It is absurd on the face of it that either companies or men should maintain military forces and wage private war at any time.

Mining and the Departments

Transfer of the Bureau of Mines from the Department of the Interior to that of Labor or Agriculture has been seriously proposed at Washington this year, and certainly some reorganization of the Department is in order. Established in 1849 and originally considered of no particular consequence, the office of Secretary of the Interior has become one of the most important in the Cabinet. The main duties centre in the custody of the public lands, though for some unfathomable reason the Bureau of Pensions was placed in the Department. The custody of the Indians, another of the duties of the Secretary, is more naturally found here, since the Indians, so long as they are wards of the nation, live upon reservations set aside from the public lands. The Commissioners of Patents and of Education also report to the Secretary of the Interior, though for

no very tangible reason. The truth is that the Department has become one for administering any bureau for which no definite place exists elsewhere. The Land Office, the Geological Survey, the Reclamation Service, and the Bureau of Mines constitute a closely related group of bureaus devoted to the study, utilization, and custody of the public lands. The Forest Service, which belongs naturally with this group, is in the Department of Agriculture, an accident due to personal factors at the time the Service was created. As it now stands, the most active Secretary of the Interior has by far too little time to do justice to needs of more than two or three of the bureaus under his charge. A time record some time since showed that three of the bureaus in the Department absorbed 92 per cent of the time of the Secretary, leaving him to apportion as justly as he might the remaining 8 per cent among the other five. No wonder there is delay, and no wonder that important matters of policy are left undecided until friction has developed undue heat. Mr. Franklin K. Lane, the present Secretary, is an experienced administrator, and is unusually well informed about the subjects that fall within the range of his office. He is hard working and faithful, but after four months in office the head of one bureau had had less than a half hour of his undivided attention.

The miners have asked and are still asking the creation of an independent department, and certainly the conduct of public business would be facilitated if some better classification of the bureaus at Washington were made. There are objections to putting the Bureau of Mines in either the Department of Labor or the Department of Agriculture as they are now constituted. As regards the first, the Bureau must make recommendations regarding mines to both operators and men, and these will undoubtedly be better received if they come from a department not avowedly consecrated to either party in controversy. In considering transfer to the Department of Agriculture, it is to be remembered that the dominant interest in the Department is likely long to be agricultural, however the name may be changed. Just now, when there are so many points in controversy between farmers and smelters, for example, the miners may naturally prefer to be independent. What is really needed is a department corresponding to that found in most Latin-American countries and called 'Fomento'; a department designed to promote development. The Department of Agriculture affords the basis for such a department, since it has the tradition that it is right and proper to spend money to encourage development. Requests for funds made by its secretary receive much more recognition from the Committee on Agriculture in the House of Representatives than similar requests made by the Secretary of the Interior in behalf of the Bureau of Mines or the Geological Survey. In the one case the Congressmen are placed upon the Committee to spend money, provided it be wisely done. In the other, the members of the Committee, exposed to demands in a multitude of directions, devote their whole energy to conserving the public funds as much as possible. The Chairman of the Appropriations Com-

mittee is looked upon as the 'watchdog of the Treasury' and usually earns his title, though, as might be suggested by the name, he is not usually adverse to the opening of an occasional 'pork barrel.'

Development projects, whether they relate to experimental farms, studies of mines, reclamation of arid land, reforestation, or gauging the streams, should not be financed upon the basis of expenditure by congressional districts. It is necessary to get away from this system, and either a new Department of Promotion should be organized or some of the accidental bureaus should be transferred from the Department of the Interior and a not too large coördinate group of bureaus dealing with the public domain brought together.

FIN

Sinking in Wet Ground

Mining engineers will read with pleasure the article by Mr. Francis Donaldson, in this issue, in which is described the methods of sinking and lining shafts on the Catskill aqueduct. It is to be regretted that costs are not also given, since those we have seen are much higher than any under which an American mining engineer is forced to work. Given money enough, almost any shaft may be sunk, but generally, since mines are by nature temporary works, capital cost is the controlling factor in choice of a sinking method. We grant freely that it should not be allowed to dictate plans so often as it does. Our Japanese friends are right when, as at the Miike mine, they build steel and brick stations and lay their underground tracks with heavy rails in rock ballast. On the average, mines are much longer lived than the material put into their equipment, and there is no economy in interrupting work to renew rails, stations, or shaft linings.

The method of grouting described by Mr. Donaldson is of much interest and may well be more widely used. Something of the same sort has been done in the lead mines of southeastern Missouri where great cracks and crevices deliver enormous quantities of water to the workings, and in other mines resort is occasionally made to the same method. Probably the most extensive use of cement for such a purpose is in 'cementing off' oil wells when a water-bearing sand is penetrated. In California, and lately in Oklahoma, this means has also been adopted in drilling through sands filled with natural gas under heavy pressure. The details of the operation have been described in a number of papers published by our local contemporary, *Western Engineering*, and need not be repeated. It is sufficient to call attention to the possibility of adopting oil-drilling methods for shaft-sinking through wet ground. Where difficulties are anticipated, it might prove feasible to drill an exploratory hole with an ordinary churn-drill, and, in case a heavy flow of water is found, cement it before sinking. In case of a large shaft, more than one drill-hole would be necessary, though if there was but one water-bearing bed, and it a thin one, it would probably be cheaper to drill the supplementary holes from the bottom of the shaft when a short distance above the already determined troublesome horizon. Has anyone tried this, we wonder?

The Sinking and Lining of Shafts

By FRANCIS DONALDSON

*When mining was begun in America timber was cheap and plentiful, the deposits of virgin coal and ore were widely distributed and could be reached at no great depths, and the development of the rectangular timbered shaft was the natural result. Nowadays shafts are becoming deeper, mining equipment expensive, and mining men are beginning to think they could possibly get better results by a part return to European methods, and by the use

the gutter and conducted thence to a pipe in the shaft running down to the pump. The interior of the shaft is thus made absolutely dry and none of the water can fall into the shaft and interfere with the operation of the cages.

Cast Iron Tubbing

Where the rock is very wet the Europeans do not believe in pumping and keeping 3000 or 4000 hp. in boilers to run pumps, so they use a shaft lining made of cast iron plates, sometimes as much as $2\frac{1}{2}$ in. thick—this is very heavy, of course, but effective. There are two types of plates or 'tubbing,' the German and the English. The sections of German tubing (Fig. 2) are made with internal flanges and are connected by heavy bolts; the English tubing sections have external flanges and are so constructed as to lock together without bolts or gaskets (Fig. 3), and are made watertight by wedging. The English sink straight through the wet rock into an impervious stratum and then set a curb ring upon which the regular tubing is built up. I am going to read an account by an Englishman giving a detailed description of the method of placing this tubing and

FIG. 1.

of permanent linings. European shafts are generally circular, about 20 ft. in diameter, and where the rock is moderately dry they are lined with brick excluding the water that may occur in the fissures. As the shafts are sunk, and at intervals of about 75 ft., iron curb rings are placed as shown in Fig. 1.

Supports for Brick Lining

A cast iron ring made of sections bolted together with a groove or gutter on the inside is placed in a notch cut in the rock. With this curb as a founda-

FIG. 3.

also illustrating the great difficulties sometimes encountered in England.

"The shaft was sunk about 9 or 10 ft. into the impermeable stratum, of the full diameter of, say, 23 ft., and then decreased abruptly to the finished size of the shaft, say, 20 ft., and the sinking was continued a further distance of 6 or 8 ft. The cradle was then lowered into the pit bottom, and a temporary wood water ring was fixed on dowels about 9 or 10 ft. above the site selected for the sides of the shaft; water was then collected in this temporary ring and allowed to run off in canvas 'hoggers' or trunks at two or three different positions to the wind bore of the pumps. As much as 6000 gal. of water per minute was collected in this manner, above the place where the sinkers were employed preparing the bed for the wedging curb, with the result that in all cases the beds were properly leveled and prepared for the curbs in the most favorable circumstances possible under such conditions.

"The cradle having been fixed in position, the sinkers proceeded to level the surface of the rock bed with mattocks, and when this was accomplished to the satisfaction of the engineer, a wedging curb, three segments of which were fitted with valves to pass gas or air accumulating behind the tubing, was laid on the bare rock, seasoned redwood sheeting $\frac{3}{8}$ in. thick was placed between all end joints, and

FIG. 2.

tion, the brick lining is built up to the ring above. As a rule the brickwork is built from a staging or platform suspended in the shaft in such a way that the sinking bucket can go up and down without interference. The lining is placed rapidly, as many as 3000 bricks per day being laid by one man. The water that comes in through various seams in the rock is drained through passages in the curb ring to

*From *Proc. Engineers' Club of Philadelphia*, October 1913.

the spaces between the back of the curb and the rock were filled with dry wood wedges to bring the inside of the curb up to the finished diameter of the shaft. Afterward well seasoned tapered dry wood wedges were driven into the wood packing between the back of the curb and the strata until the steel chisel points refused to enter. Then a layer of $\frac{3}{8}$ -in. horizontal sheeting was placed on the top of the wedging curb, and the 2-ft. foundation course of tubbing was put on, breaking joint with the curb, $\frac{3}{8}$ -in. end and horizontal redwood sheeting being placed between the joints, and the course was brought up to the correct radius of the shaft by means of wood packing. Next one or two courses of plain tubbing were put on, the fourth course usually containing three or more special segments (technically termed 'valve segments'), cast with holes of 4 to 6 in. diameter in the centre, with the object of permitting the water to pass from the back to the front side of the tubbing, and so to the pumps, when the temporary wood water ring was removed.

Method of Wedging

"The next operation was to wedge lightly the vertical joints of the three or four courses of tubbing, and to run the whole up solid with good cement grout. The temporary water ring was then removed, and additional courses of ordinary tubbing were built on, to a total height of about 60 ft. The joints were now lightly wedged, commencing from the top with the vertical joints, and from the bottom with the horizontal seams, using redwood wedges. Additional courses of segments of suitable height being used to close up to the wedging curb above, the vertical and horizontal seams were again twice wedged alternately as before, and the small centre holes in each segment were plugged. Finally the large holes in the valve segments passing the feeders were plugged simultaneously, with long tapered plugs of wood, the excess being sawed off flush with the front side of the orifice, the cast iron caps were bolted on to the flanges, and the shaft was rendered dry if the work had been well carried out."

These two shafts were sunk by John Joseph Prest at Horden; through magnesian limestone, in north-east Durham county. Six thousand gallons of water per minute was pumped out of one shaft.

The reason I read all that was to show to what trouble and expense they go to in Europe to get a tight shaft. A $2\frac{1}{2}$ -in. cast iron lining 20 ft. diameter is very expensive.

Working in Wet Shafts

As long as we are on this subject of wet shafts, I may say that I wrote Mr. Prest and asked him how he could get men to work in the shaft with 6000 gal. of water coming in every minute. Somewhere in this article he says that the water as a rule was 3 ft. deep. He wrote back to me as follows: "I am in receipt of your letter, and in reply thereto I beg to inform you that after a round of holes is fired, the material is loaded up from the pit bottom in the ordinary way, and when exceptionally large stones are met, the sinkers dip down below the water and collar hold of them, as you suggest. It is not customary in this part of the world for sinkers to wear anything ex-

cept rough flannel trousers and shirt, with a waterproof backskin, when sinking, and in the case of our shafts the sinkers are wet through practically the whole of their shift except on the back. Sumps are made under each set of pumps, and are kept as much as possible in advance of the pit bottom, and holes are drilled systematically round the whole of the shaft bottom to a depth of six or seven feet, as required, and are fired electrically from the surface. Under ordinary conditions, a new section of wet spear rod can be put on and bolted up in three hours; when any additional ground spears were required, the time occupied was usually from 9 to 12 hours. The maximum boiler horse-power in use at any one time would not exceed 3000."

The water was handled by the old type Cornish pumps and the method has not been improved.

In 1838, the Murton shafts were sunk and there they handled 9300 gal. of water from a depth of 450 ft., where the impervious rock began. This is a greater quantity than we are able to handle in sinking in this country today with all modern appliances. It is generally known that the Europeans are away ahead of us when it comes to difficult mining problems.

Sinking in Soft Ground

The Kind Chandron process has been developed to bore a shaft 15 ft. diameter from the top to a depth of 600 or 700 ft., to line it with cast iron tubbing and to seal it to an impervious stratum without a man going down into the shaft. The Europeans have also evolved a sinking drum system similar to our caisson method, but on a more extensive scale. They sink a circular masonry caisson for 50 or 60 ft., building into the upper part a cast steel reaction ring, then build up circular cast iron tubbing with an outside diameter slightly smaller than the inside diameter of the caisson. From the bottom to the under side of the reaction ring a heavy cutting edge is provided. Powerful hydraulic jacks are placed between the reaction ring and the top of the tubbing, and the whole thing is jacked down, rings being added and the material being removed with a grab bucket. In that way they have penetrated five or six hundred feet in quicksand without anybody going down into the shaft. In this country when we go down 150 ft. without anybody going in the caisson, we think we have done a particularly remarkable piece of engineering.

Brick or cast iron will not wear out; they are safe against fire, and in a long lived mine are cheaper in the end than less permanent linings. On the other hand, they call for a circular shaft, and in a shaft with several compartments rectangular construction is much more economical and includes less waste of space than any other. In Europe the development has been largely due to the geological conditions. The Europeans have been forced toward their methods by the fact that the coal and the minerals are all deep down; they have had to go down through great depths of marl and limestone. Ninety per cent of the total footage of shafts in this country is in solid rock, and our problem is to meet the European requirements of safety, permanence, and the exclusion of water without going to the great expense

that they are put to in lining shafts in soft ground.

In pursuance of this idea a number of mining companies in this country have sunk shafts and lined them with concrete. The United States Coke & Coal Co. was the pioneer and they sank two elliptical shafts in West Virginia about 200 ft. deep and lined them with concrete. About three months after the mine started operation there was an explosion which wrecked the mine and killed eight or ten people, but the shafts were not injured in any way, and the operation of the cages was not stopped for an hour. The officers were able to go right ahead with their work of rescue and the rehabilitation of the mine itself.

The Catskill Aqueduct

It is only lately that the European requirement for the exclusion of water has been met, and that has been done on the Catskill aqueduct. The condition

was tried there for the first time in this country. The shaft was full of water, so they put in a platform as low as they could, installed a diamond-drill, and drilled six 90-ft. holes in the bottom of the shaft. They pumped them full of cement grout, forcing it through the diamond-drill easings. Before they went much farther they encountered another leak of about 750 gal. per minute; as they drilled the bottom the water poured in through the machine drill holes they were going to shoot. So they simply plugged up those holes, then removed the plugs one at a time, drove in pipes connected to a grouting machine, pumped grout into the holes, and cut the water off that way. By that means they were able to reduce the flow until they could put in a permanent pump station and handle the water.

Plugging Seams

The next shaft on the aqueduct where water was encountered was shaft No. 4 (which I had charge of), in New York City, Borough of the Bronx. We went ahead and made good time until we got to a depth of about 100 ft. We were then drilling into the bottom when we struck a stream of water of about 150 gal. per minute in the first hole we drilled. We plugged that with a hard-wood plug and cut the water off, drilled another hole and got the same flow, and so on all around the shaft. We drilled 12 sump holes, all pointing in, and found water in all of them but two. We saw there was no use pumping them, and we made ready for grouting. I would like to describe the method by which we choked off the water.

As soon as each hole cut the water-bearing seam we plugged it, as stated above, with a tapered wooden plug. After all the holes in the sump had been drilled and plugged in this way, we made the grout connections one at a time so as to restrict the flow of water into the shaft. Each connection is made with a piece of 2 or 2½-in. iron pipe about 3 ft. long. This is threaded at one end and given a long taper at the other. The tapered portion is made rough on the outside by nicking it with a chisel. A heavy iron 'stop cock' is screwed to the pipe, the tapered end is wrapped in several thicknesses of burlap, the wooden plug is then removed from the drill-hole, and the tapered pipe driven in, the stop cock being left open. This is the most exciting and wettest part of the job. After the pipe has been driven in hard the stop cock is closed.

Grouting Machines

In this case we put connections in all the wet holes before grouting. The grouting machine or tank used on the aqueduct was the Canniff machine (see Fig. 5) in which the grout is mixed by air. It is built like an air lock with a door on the top through which cement, sand, and water are introduced, a 2-in. discharge opening in the bottom and air connections top and bottom. The discharge opening is connected to the grout hole by a heavy rubber hose. Another 2-in. stop cock is placed at the outlet of the tank and a 2 by 1-in. tee is placed between the hose and the cock attached to the pipe in the drill-hole. Into the side opening of this tee a 1-in. stopcock is screwed.

FIG. 4.

has been met by cement grouting. The T. A. Gillespie Co. had a contract for the Rondout siphon, which was a deep circular pressure tunnel under the Rondout valley. The tunnel was about five miles long, and it was expected that they would meet considerable water. They did not, however, except in one shaft which was put down on a fault between limestone and conglomerate; great quantities of water were encountered here. This shaft was sublet to a Pennsylvania contractor; he struck about 1500 gal. of water per minute, put in all the pumps he could get, and could not do anything with it. The shaft had reached a depth of 350 ft. when it stuck. There had been a lot of water coming in on the side of the shaft (Fig. 4)—a rectangular construction shaft, by the way, lined with timber—and when the sinkers struck two or three more fissures in the bottom and got still more water it was the last straw and it broke the back of the pumps. John P. Hogan, a division engineer of the Board of Water Supply, then suggested that cementation be tried, and it

The machine is taken to the bottom of the shaft, is connected to one of the holes and also connected to the high-pressure air-supply. The 2-in. stopcock on the machine is closed and the other opened. The door in the top is opened, a sack of cement, three or four buckets of water, and, if the cavity to be filled is large, a sack of fine sand, are poured in, the air connection at the bottom is opened and the air allowed

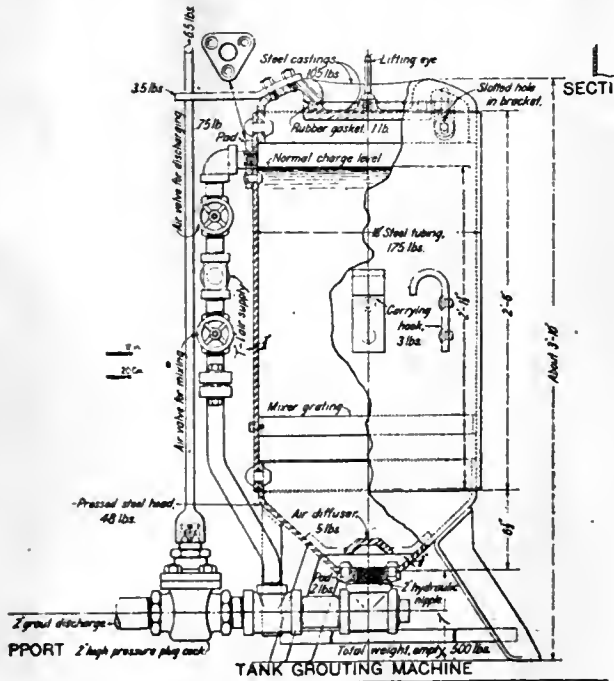

FIG. 5.

to bubble through and mix the grout. Then very quickly the door is closed, the lower air connection is closed, and the discharged connection and the upper air connection are opened and the air enters and drives the grout into the cavity. A man stationed at the 1-in. stop cock keeps opening into a crack; when air shows instead of grout he closes the 2-in. stop cock and the machine is recharged. If the cavity is open the charge is injected in three or four seconds, and by working continuously over a thousand batches can be placed in 24 hours.

The Use of Cement

In one hole on the aqueduct we put in 4000 sacks of cement before the fissure was entirely filled. In shaft No. 4 we put in about 100 in the first fissure. A little farther down in this shaft we encountered a layer of sand. The rock is folded very much; the sand was formed by the crushing of the rock due to the folding, was pretty fine and was carried up out of the drill holes by the water. Grout will not permeate sand and we had to continue drilling holes and pumping in grout, raising the pressure at the end from 100 to 400 and 500 pounds to the square inch. We tamped that sand so full of cement that when we sunk through it it was compacted like sandstone. We found big balls of grout when we cut through it, some as big as a man's fist and some as big as his head.

The most interesting piece of grouting was done on the Hudson siphon, which is a deep siphon tunnel under the Hudson river; 14 ft. diameter inside the concrete lining, and at a depth of 1100 ft. below tidewater. There was practically no water in the

rock and the shaft sinking was done by the city forces. When they reached the bottom they concluded it would be cheaper to turn the job over to a contractor, and this contract was let to The T. A. Gillespie Co. On the east side of the river the city had driven 200 ft. of tunnel through dry rock when the men broke into a stream of water which flowed 300 gal. per minute. They struck it at night, and the shift boss shot his holes and broke away all the rock that should have been there to fasten the grout connections to. When we saw the job we decided the next thing to do was to build a concrete bulkhead. We boarded up the face and put in 8 ft. of concrete across the full tunnel section (at this point a top heading 7 ft. high and 14 ft. wide) and then reinforced it with rails. The concrete was mixed 1:2:4. We let the concrete set for a week and then started grouting. Grout pipes were put through the bulkhead, terminating in the fissures. At an elevation of 1100 the hydrostatic pressure is 500 lb. per sq. in., and we had hard work to force in any grout against it. We had eventually to raise the pressure to about 1000 lb. per sq. in., and to do this we had to use a high-pressure plunger pump and pump water in on top of the grout in the tank. We put two ear-loads of cement into that hole, and after it was set up for a week we shot the bulkhead out and went ahead with the tunnel.

The contractor for the lower end of the city tunnel in New York has encountered a good many streams of water at depths up to 500 ft., and has grouted them successfully.

Where we met the sand bed in shaft 4 we were unable to get the water entirely shut off and we had to rely on the concrete lining to get the shaft entirely dry. In good rock as in the Hudson siphon a con-

FIG. 6. SAND FORMED FROM CRUSHED ROCK IN NO. 4.

crete lining is not needed in order to cut off most of the water because if you drill into the seams you can grout them off. On the other hand, if the rock is very much fissured it is practically impossible to grout it. When this is the case it is necessary to design a concrete lining strong enough to withstand the total water pressure that can come against the outside. In the case of an elliptical shaft that lining has to be thicker on the sides than at the ends; you can figure the stresses on the concrete if you are a good mathematician. We have found that 1:2:4 concrete 18 in. thick in a 14-ft. tunnel will stand 600 lb.

to the square inch. Anything higher than that broke it.

If you met a little stream, just a few drops per minute, a pipe must be set in opposite that stream and the water led through the lining. After this concrete has set two or three weeks and is good and hard you connect the grout machine to this pipe, drive a little grout in, and stop the water. It is absolutely impossible to stop water coming through concrete when it is soft. You have to provide a drain until it sets. In one case we overlooked a small spring, and after we had concreted about 60 ft. of shaft above it, we noticed the forms bulging over an area of about 10 ft. square. We found that the accumulated pressure from the little spring had pushed the lining out over this area and we had to cut it out and replace it.

Shape of the Shaft

The question of a water-tight lining brings up the shape of the shaft. The shaft with the maximum area and the minimum lining is of course circular, and this is by far the cheapest shaft to sink. That was proved on the aqueduct. All the construction shafts at first were made rectangular and lined with timber, while the waterway shafts were made circular. On the Rondout siphon shafts we started out with the idea that the rectangular shafts would be easier than the circular, but it was the other way. When we started the first circular shaft we did not do much the first month. The last month we made 138 ft. The next siphon we moved to we had the same gang, and they knew how, and jumped the progress up to 170 ft. in one month in shale. The same gang was then moved across the Hudson river to a granite shaft, and we made 183 ft., which is the American record.

The way it was done is this: The drilling is all done on one shift. Enough drills are put into the shaft so that all the holes in the round can be drilled and the sump loaded and shot in eight hours. The other two shifts clean out the shaft and get it ready for the drilling shift the next morning. We drilled 33 holes to a round.

The same method is used in South Africa on rectangular shafts, but in this country it has not been successful in rectangular shafts. I personally have tried it in four shafts and it would not work. However, in circular shafts we tried it and made it work.

I mentioned the rectangular construction shafts being slower to sink than the circular. In South Africa they hold the world's record for sinking, and the shafts there are rectangular. In this country most rectangular shafts are about 12 by 26 ft. and about 10 to 12 men are used on a shift. There will be two or three drill runners, three helpers, and about six shovelers. In South Africa they use 35 to 40 men on a shift in a shaft of the same size. I was talking to a man from South Africa who had been engaged on some of this sort of work out there, and I asked him how he could get so many men in. He said they use Kaffir labor. These Kaffirs wear no clothing to speak of, and the temperature gets up to a great height with 30 or 40 men all bunched together; they sweat and their greasy bodies just slide past each other without any trouble. He said

that the smell down there is so strong that when a little bit of rock is dislodged, it just shoots right up out of the top of the shaft of its own accord.

Wherever the entire area of a circular shaft can be used, as for ventilation, a circular shape is best. Where this is not practicable, as in a hoist shaft with several compartments, the best plan is to cut the ends off the ellipse adopted by the U. S. Coal & Coke Co. and make a compromise between an ellipse and a rectangular out of our circular ares. In dry or moderately dry rock the concrete lining need not be over 15 to 18 in. thick, but in wet and seamy rock it must be thick enough to resist the hydrostatic pressure after the shaft is lined.

In New York City lately the contractors have been putting in as high as 25 to 30 ft. of concrete in a 14-ft. circular shaft, and in six days, including getting started, putting the forms in, and taking them out again, they will put in 100 to 120 ft. The cost of a concrete lining is greater than the cost of a timber lining by just about the cost of the cement. As a rule, concrete outside the cost of the cement can be put in for the price of the timber; you have to pay for your cement and you have a permanent lining.

Production of Gold and Silver in 1912

The production of gold and silver in the United States from domestic ore in 1912, according to a recent publication of the U. S. Geological Survey, is shown in the following table in distribution by states.

State or Territory.	Gold.		Silver.	
	Quantity.	Value.	Quantity.	Commercial value.
Alabama	795	\$ 16,400	200	\$ 100
Alaska	831,981	17,198,600	539,700	331,800
Arizona	183,117	3,785,400	3,445,500	2,118,000
California	967,887	20,008,000	1,384,800	851,200
Colorado	906,606	18,741,200	7,933,100	4,876,500
Georgia	526	10,900	200	100
Idaho	67,810	1,401,700	7,862,900	4,832,400
Illinois	1,800	1,100
Maryland and Pennsylvania .	60	1,200	700	400
Michigan	543,500	334,100
Missouri	30,000	18,400
Montana	179,371	3,707,900	12,524,000	7,698,500
Nevada	656,722	13,575,700	13,851,400	8,514,400
New Mexico	36,506	754,600	1,460,800	898,000
North Carolina..	7,544	156,000	2,300	1,400
Oregon	36,749	759,700	54,000	33,200
Philippine Is.	22,331	461,600	5,800	3,600
South Carolina..	744	15,400
South Dakota....	378,470	7,823,700	205,800	126,500
Tennessee	557	11,500	112,000	68,800
Texas	105	2,200	379,800	233,500
Utah	208,623	4,312,600	13,076,700	8,033,300
Virginia	14	300	700	400
Washington	33,023	682,600	350,800	215,600
Wyoming	1,176	24,300	300	200
Total	4,520,717	\$93,451,500	63,766,800	\$29,197,500

The figures in this table are also those of the Director of the Mint. They result from coöperation of the U. S. Geological Survey and are agreed upon after conference and adjustment between the two bureaus. They are, therefore, final for both. The totals are based on bullion deposits in the United States mints and assay offices and on returns to the Bureau of the Mint from the smelting and refining companies. The distribution is adjusted by information collected by the U. S. Geological Survey direct from the producing mines and tabulated for the mine reports later discussed. The data giving the total production, and in part the distribution, are obtained from government and private records.

La Plata Mountains, Colorado

By RENSSELAER H. TOLL

Recent discoveries and exploration in the La Platas, in the southwestern corner of Colorado, recall the early days of forty years ago, when the land belonged to the Indians and no white men except a few adventurous explorers and prospectors had penetrated the fastnesses of these rugged hills in the eternal search for gold.

First Gold Discovery

It was late in 1873 that Capt. John Moss, an old-time California miner and the first promoter known to the La Plata district, saw at Del Norte some rich specimens of gold ore which had been brought from

was named—as was fashionable at that time and for many years after—the Comstock; and for some time it gave promise of proving a worthy namesake of the mine that made Nevada famous. The ore was extremely rich, and the shoot was about forty feet long and from three to four feet wide. Operating expenses at that time were naturally enormous, and old-timers state that in the case of this property the extravaganees were even larger than the expenses. Ore was hauled by ox-teams to Pueblo, a distance of 350 miles, over three mountain ranges, one-third of the distance there being no road; and supplies were brought in from this point.

LOOKING DOWN LA PLATA RIVER FROM THE MOUTH OF BOREN GULCH.

the La Plata river by some roamer whose name became lost too early to become inscribed on the roll of fame. Moss immediately purchased the property from which the ore had been taken and was soon upon the ground.

A considerable 'stampede' was created by the news of this discovery and of others which soon were made, and at the mouth of La Plata cañon quickly grew a money-mad border town, duly christened Parrott, that being the name of the backers of Moss, who were bankers of San Francisco. Parrott City being the only town in La Plata county at that time, it was, perforce, the county seat; but all signs of the important position of this once thriving camp have been removed, and its namesake is now situated a mile eastward at the end of the railroad spur and near the productive Idaho and May Day mines.

The lode on which the first discovery was made

Colorado Springs, or Denver, an important item of 'supplies' being a barrel of whisky which was set up on the dump at the mine, the head knocked in and tin cups hung about the chime for the benefit of white men and Indians.

Decline of the Property

This ore was too good to last, however, and at a depth of 40 ft. the high-grade disappeared. The shaft was continued to a depth of 85 ft. and about a hundred feet of driving done without encouraging results. The property was then allowed to revert to the state of 'innocuous desuetude,' despite a well authenticated production of \$75,000 to \$80,000 from the small space mentioned. These figures may sound mythical, but there are a number of men of veracity in that district and elsewhere who knew the property in the early days and who testify to the extreme richness of some of the ore which was shipped.

Within recent years lessees have shipped several carloads of ore from near the old workings which assayed about \$100 per ton, and a small pocket was discovered on the surface which was almost half calaverite.

This property has been idle 36 years out of the last 38, and the shaft has never been extended much since the early days, being but 160 ft. deep now; while the drifts are less than 300 ft. in total length, all the work having been done close to the original orebody, without development of new ground which may contain bodies of ore equal to the first.

The Comstock is cited not so much for its historical interest as because it may be said to be typical of the old properties of the district, their usual history being: a small production of high-grade ore, desultory gonging about the edges of the ore-pocket, abandonment. Many became involved in litigation, original interests passed to heirs, some holdings were sold for taxes, and many titles became complicated so that the real ownership was hard to determine. The Small Hopes, Cumberland, Bessie G., Durango Girl, Bulldozer, Jenny Lind, and a dozen others have histories very similar to the one above related, the principal difference being that they are farther from the railroad and not so easy of access.

Lack of Development

Considering the richness of the ore and the excellent showing made in recent years by the Neglected, May Day, Idaho, and other mines of less importance, it is surprising that so little real development has been done in these mountains. A good deal of money has been wasted on mills and other equipment where it was not justified, and some forlorn hopes have been followed in an expensive and disappointing manner; but there are good prospects which are worthy of considerable judicious development. The best two mines of the district are finds of recent years which had been overlooked for a third of a century. Perhaps some of the old-time producers would do as well with equal development.

At present there is little prospecting being done except in the region of the La Plata river, where the Idaho and May Day employ 30 to 40 men each and maintain a steady output. The Bay City and the Southern Boy are being operated by lessees and some ore is being taken out; and the Lucky Moon company is placing a compressor plant at Comstock and laying a mile or so of air-pipe to the mine high up on the mountain, where extensive development is planned.

Near the mouth of Madden gulch, about a mile below La Plata City, some Denver mining men are prospecting the placer and underlying ground by means of a diamond-drill. This placer, it may be mentioned, contains a considerable quantity of coarse gold, and about twenty years ago an effort was made to operate it profitably, and systematic work was begun by the company which owned about four miles of the bars; but quarrels and threatened litigation discouraged the work and nothing has been attempted since. With modern equipment and economy these extensive bars and channels might

be very profitable, but considerable capital would, of course, be necessary for such an enterprise. The many large boulders and the floods which often occur in the early fall are serious but not insuperable drawbacks, for the area is large enough to admit of large equipment and operation on an extensive and economical scale.

The Copper Hill Property

About a mile west of La Plata City is the Copper Hill, the only copper mine which was ever operated in these mountains. The deposit is low in grade, averaging 4 to 5% copper, but it can be worked on account of its favorable position near the Durango smelter, where a very low treatment rate is obtained because of the desirable nature of the ore. The mine is worked by adits, the lower one cutting the orebody at a depth of nearly 300 ft. The production amounts to four or five carloads per week.

The Eureka-Bulldozer is pushing development and producing a small amount of high-grade ore. The Ten Broeck has several men employed on development and is expected to become a producer in the near future. The Lightner Creek Consolidated is doing considerable work on very promising veins which years ago produced high-grade ore. Much prospecting and development over the central portion of the mountains is evident.

One feature of the La Plata district, which is in common with many others and strikes the most casual observer unfavorably, is the number of idle mills which are scattered over every portion, hardly a gulch being free from one of these mournful monuments to false hopes. A few of them were built in the best of faith (or, should it be said, the *worst* of faith?) on insufficient ore reserves or for ore of unsuitable character; but many were merely used to further stock-selling campaigns or to beguile small stockholders into the belief that they were getting something for their money.

Almost every type of apparatus and every known process is exhibited in these mills except modern developments of the cyanide process and the latest concentrating devices, for no mills have been built during the past half-dozen years. This machinery is in most cases practically as good as new, not a single mill having ever been operated for any length of time.

Types of Mills

They vary in character from the arrastre plant erected on the Comstock in the early '80s to the elaborate bromination mill of the Cumberland, which mistake was committed in the late '90s and cost a Swiss company probably \$50,000. Metallurgically, it is said to have been a great success, for the recovery was high; but the small item of operating costs had evidently been overlooked when the estimates were made, and the ore proved to be too poor to bear the milling cost of \$18 per ton; otherwise, it probably would have been shipped to the Durango smelter. In 1904 this mill was supplanted by a cheaper amalgamating and concentrating plant, in which the cost of operation was no doubt materially reduced, but apparently not enough

for the grade of ore to be treated. It seems strange that, in a district where several properties have recorded productions of hundreds of thousands, and two properties have produced millions of dollars each, there should be no bodies of ore of sufficient size and value to supply a mill profitably; but the record of failure, which has been made, is not conducive to confidence in the future.

The Neglected mine, which made a large production of high-grade ore in 1902 and 1903, and has been involved in litigation most of the time since, is credibly reputed to have a number of bodies of milling ore developed; and it would naturally be expected that the two largest producers of the present time would be able to support a small mill, at least. But these are exceptional. The striking feature of the district is the richness of the ore. When ore is present it is rich and not on the border line

produced by this district during recent years is \$40 to \$75 per ton, according to government reports. Because of the richness of the ores—which, by the way, are usually tellurides—this district is more of a 'poor man's camp' than those whose low-grade ores require a large expenditure of capital for development and equipment. The May Day mine, which was discovered about eleven years ago by a poor prospector, on a trail which had been tramped over for 30 years, was sold for \$50,000 when the shaft was but 10 ft. deep; and the Lucky Moon, which was stumbled upon by a farmer boy in 1909, was sold for a like sum and the money paid before the discovery cut was below the grass roots.

Naturally, they are many old time prospectors in the hills who have not had any such luck; but there are chances yet, for the territory has not been half prospected and none can say with any assurance that all the rich mines have been discovered. There are chances for the poor prospector in new discoveries, as well as for capital in developing some of the former producers.

The above features of the district have been used to the utmost advantage by unscrupulous promoters in selling stock in many worthless or highly speculative enterprises. Also a great deal of handsome but valueless paper is scattered over the land, representing minute interests in grossly overcapitalized corporations, greatly to the detriment of the district and the annoyance of honest claim owners and operators. However, this state of affairs is not confined to the La Platas alone, being one of the inevitable consequences of success, as every worthy field of production or endeavor soon becomes crowded with impostors, and the layman knows not the false from the genuine.

The district is much more favorably situated for economical operation than the higher and more rugged country known as the 'San Juan.' Along the southern border are extensive fields of the best lignite coal, a railway spur extends from the main line to the mouth of La Plata River cañon, and the entire area is well wooded, providing excellent timber for all purposes. A large hydro-electric power-plant is situated on the Animas river at Rockwood and supplies power along that stream and to the towns north of that point. Its lines might easily be extended to any portion of the La Plata mountains were the service required.

The total production of natural gas in Oklahoma in 1912 as estimated by David T. Day, of the U. S. Geological Survey, was 73,799,319,000 cu. ft., valued at \$7,406,528, or 10.04c. per 1000 cu. ft., compared with 67,275,608,000 cu. ft., valued at \$6,731,770, or 10.01c. per 1000 cu. ft., in 1911.

MAP OF LA PLATA DISTRICT.

between ore and waste—it is either rich or worthless. The orebodies are usually sharply defined, and though comparatively small, they make up in value what they lack in size.

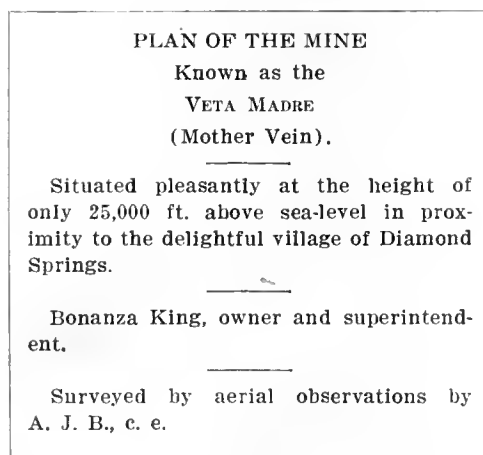

Grade of Ore

Small shipments from various mines have assayed several hundred dollars per sack, and many carload lots have returned \$1000 to \$2000 per ton. One shipment from the Idaho mine to the Omaha smelter brought a check for about \$34,000 for about 14 tons, and a carload from the same property which recently was shipped to Durango under armed guard, is said to have assayed \$2500 per ton. In passing, it may be said that the present daily production of this property is said to be about \$1000.

The ore is closely sorted, the largest mines using mechanical washers, and everything that will pay to ship (and, no doubt, a good deal that will not) is sent to the smelter; the remainder, mixed with waste from development, making a pretty lean dump, even though the average value of the ore

Possibly a Joke

*We present below a reproduction of an old drawing found recently at Diamond Springs by P. R. Bradley, and purporting to have been used to illustrate a report on a property near that place, made by an English engineer some years ago. The report itself, unfortunately, has not been preserved, and there are elements in the drawing that suggest doubt as to the serious purpose of the artist. Indeed, one of the members of our staff, himself a citizen of the British Empire, has suggested that the whole thing is a joke. As the Englishman is popularly reported to be unappreciative of humor, we pass the responsibility of deciding this point to our readers. The drawing is entitled:

The numbers refer to footnotes as below.

1. Mount Babel, altitude 25,000 feet.
2. The Mother Vein.
3. Mount Cheops, proposed location for stamping-mill.
4. Location of material for making the regular monthly reports.
5. Mount Acme, proposed location for superintendent's house.

*Note by the Editor.

6. Line where animal life is impossible.
7. Line of perpetual snow; mercury froze.
8. Antediluvian mill left by primeval miners.
9. Proposed aerial bridge.
10. Balloon refuses to ascend, specific gravity of air lighter than balloon filled with nitrogen.
11. Proposed tunnel, length 8000 ft., through an adamantine material; with double diamond-drills progress may be made at the rate of six inches per day.

†Indicates cemetery, and residence of the town physician, who earns his livelihood in repairing the fractured bones of those who make the ascent to the Mother Vein. He is very poor, from the fact that in most cases patients leave their bones, fractured or otherwise, in Death Gulch.

Note B.—The sign over the door of Shrewd, lawyer, announces that parties desirous of ascending to the Mother Vein will find it much to their advantage to have their last will and testament filed with him before undertaking the journey—rates reasonable. Shrewd is considered to be very wealthy.

Steel Sluiceway Linings

By W. W. EDWARDS

When the pay-dirt in a gravel bank is highly concentrated, the economic working of the mine depends less upon the sluiceway than upon the miner's success in following the streak. In such cases any kind of sluice lining will do; blocks, stone paving, or any other material which will make riffles and protect the flume bottom from wear. But when, as is frequently the case, the gold is disseminated through a bank of gravel in rather small quantities, the miner's success depends considerably upon the wearing and gold-saving qualities of the sluiceway. A little experience in lost time due to

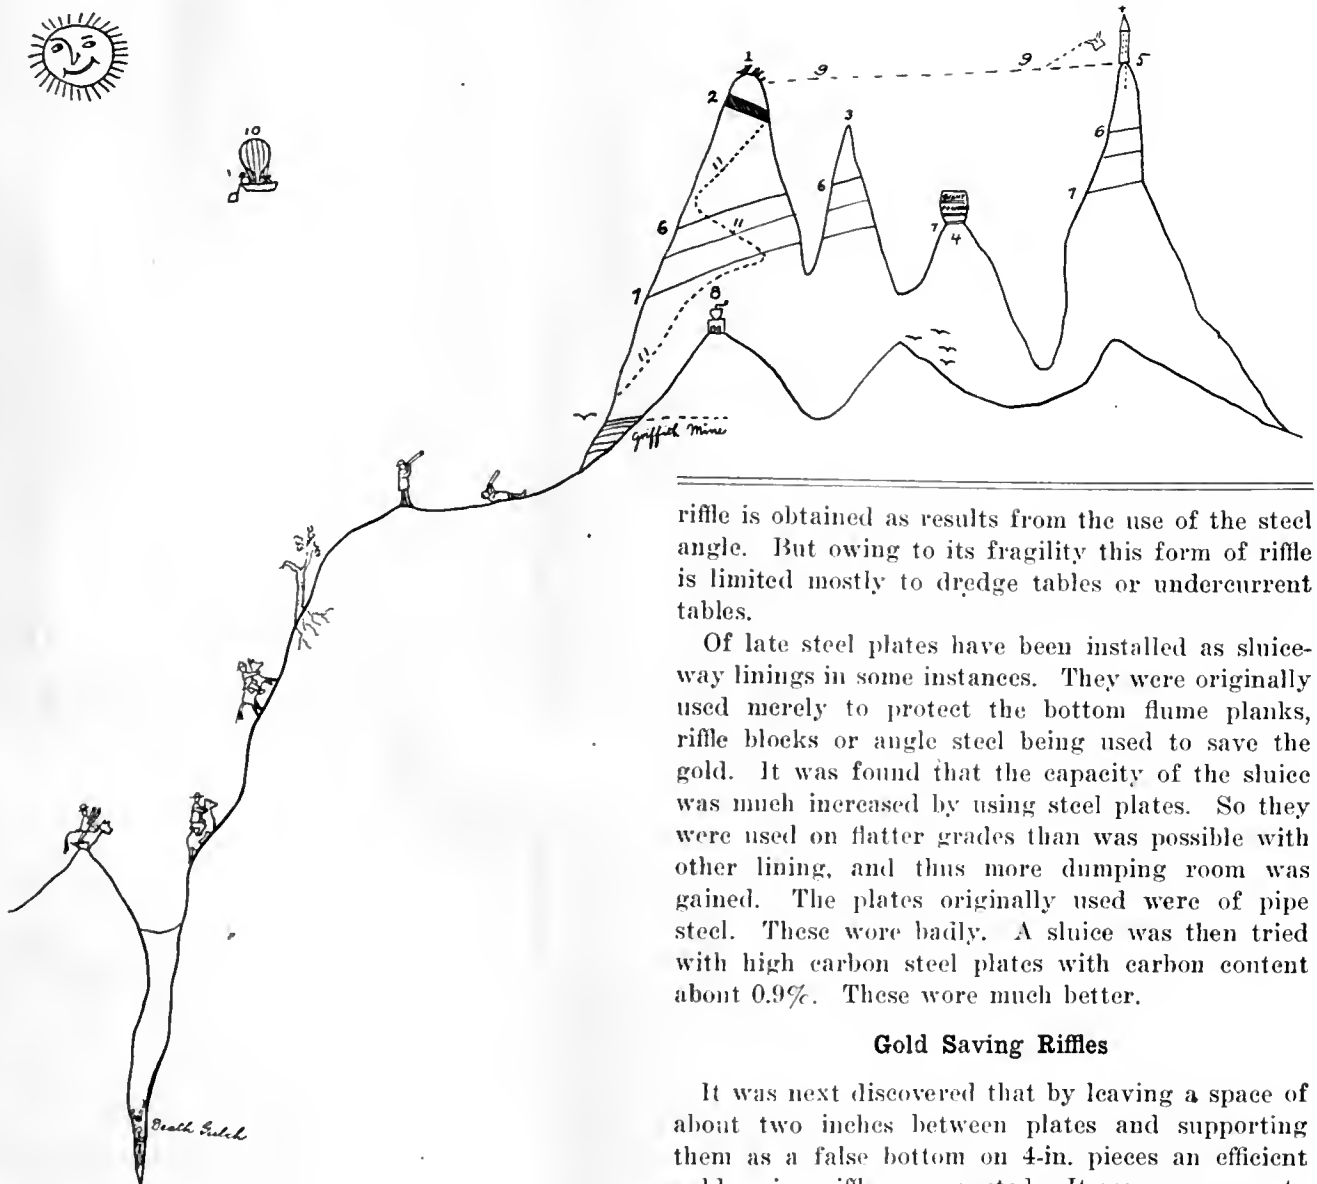

patching paving, cleaning-up, and replacing blocks or stone in the middle of a season's run, demonstrates this forcibly. To remedy these difficulties, steel in some form of lining is adopted. There are four ordinary ways of using steel in sluiceways: as rails, angles, cross-strips, or plates.

Rails have been used both lengthwise and cross-

wise of the sluice. Experience generally shows that crosswise is the best way. Then the wear is more evenly distributed and is not so heavy. When the rails are put in lengthwise, small rocks wedge in between them, and the passing stream of rocks and boulders batters the rails, especially those in the centre of the sluice. On cross-riffls, the wear is dis-

tributed. Thus the wear obtained from steel angles is not economical for the weight of metal involved.

Steel cross-strips have been used where the material run is very light. They are screwed to the tops of wooden strips placed crosswise in the sluiceway. They are so fastened that their lower edge overhangs the wooden strip. Thus the same kind of

tributed. Rails placed crosswise make an efficient gold-saving riffle until the top gets worn down, after which the rails serve only to protect the bottom planks from wear. Ordinary carbon steel rails wear out fairly fast, but good wearing results can be obtained from manganese steel rails, although the first cost is high. Sluiceways lined with cross-rails have been used in mines where the total operating cost did not exceed three cents per cubic yard.

Steel angles have been used effectively in sluiceways. Placed as they always are with the flat side pointing down stream, they make what is probably the most efficient form of riffle for gold-saving purposes. Their wearing qualities are, however, not so good. The wear is concentrated in the middle of their length, directly upon the right angle edge. This soon wears through; the two flanges split apart, are bent down stream, and the angle must be taken

out. Thus the wear obtained from steel angles is not economical for the weight of metal involved. But owing to its fragility this form of riffle is limited mostly to dredge tables or undercurrent tables.

Of late steel plates have been installed as sluiceway linings in some instances. They were originally used merely to protect the bottom flume planks, riffle blocks or angle steel being used to save the gold. It was found that the capacity of the sluice was much increased by using steel plates. So they were used on flatter grades than was possible with other lining, and thus more dumping room was gained. The plates originally used were of pipe steel. These wore badly. A sluice was then tried with high carbon steel plates with carbon content about 0.9%. These wore much better.

Gold Saving Riffls

It was next discovered that by leaving a space of about two inches between plates and supporting them as a false bottom on 4-in. pieces an efficient gold-saving riffle was created. It was necessary to raise the lower end of each plate about $\frac{1}{4}$ in. above grade so as to keep material from striking the upper end of the plate next below and wearing the edge. With these plates the maintenance charges were much reduced.

The plates are held in place by the lining boards. They are easily put in, taken out, and cleaned up. They will stand the season's wear, and hence stoppages to fix paving are unknown. When badly worn on one side they can be turned. If the size of the sluiceway permits of their being made square they can be practically worn out before their usefulness is impaired. The plate lined sluice has a much greater capacity than a block or rock paved or even a rail or angle paved sluice, thus permitting a saving in grade and consequent increase in dumping facilities.

Plates such as these of 1.25% carbon content, 58 in. square, and $\frac{1}{2}$ in. thick were placed in a sluice-

way with a 4% grade. Forty-pound manganese steel rails on a 5% grade were used at the head of the sluice feeding to the plates. After one season's work during which 600,000 cu. yd. of gravel was passed over the plates, scarcely any wear was apparent, and the total life of the plates was estimated at 10,000,000 cu. yd. On this basis the material was handled at a total operating cost of 2c. per cubic yard, which figure includes all charges of water-supply, maintenance as well as operating expenses, and an allowance for sinking fund to replace the plates when worn out. This cost compares favorably with a previous cost on the same property of 4c. per cubic yard with wood blocks and stone paving.

One objection raised against the plates is that the gravel passing through is not sufficiently churned up to separate all the gold particles and give them a chance to get into the riffles between plates, but that the material rather slides through the sluice. This can be remedied by putting in some rail cross-riffles at intervals. A good combination for all purposes is high carbon steel plates coupled with a few manganese steel rails.

It is, of course, not always necessary or even possible to use steel lining in a sluiceway. Transportation facilities to a placer mine are generally poor. Freight charges are consequently high. Again, the percentage that the sluiceway operation and maintenance bears to the total operating cost of the mine may not warrant anything better than block or rock paving. But it is certain that an investigation of the cost of steel linings is well worth the trouble whenever success depends largely upon steady running and the handling of a big yardage.

Copper From Mine Water

STAFF CORRESPONDENCE

From the two working shafts of the Penn copper mine, Calaveras county, California, a total of 30,000 gal. of water is bailed daily. This averages 15 lb. of copper per 1000 gal. It is run through 14 boxes, 9 of which are 2 by 3 ft., and 5 are 1 by 2 ft. in section, having the common length of 100 ft., with a fall of 6 inches in each length. These are filled with all kinds of scrap iron and refuse from can factories on the coast. The copper is precipitated on this scrap. The boxes are cleaned once a month, the large scrap being lifted out, and the finer material put through a 16-mesh screen. The precipitate is dried, sampled, and shipped to an Eastern refinery. It averages 70% Cu, and the monthly yield is 7 tons, all produced at a low cost.

Gold and silver production of Charters Towers, Queensland, during September was worth \$105,000, from the treatment of 6494 tons of ore and 5583 tons of tailing.

The Elmore vacuum plant at the mines of the Sulitjelma company, Norway, produced 1170 tons of copper concentrate during October.

In a cross-cut on the 1300-ft. level of the Waihi mine, New Zealand, a vein of good appearance has been opened.

Zinc Ore Deposits in Boone and Marion Counties, Arkansas

By KIRBY THOMAS

The zinc ore deposits near Zinc, a station on the White River division of the Missouri-Pacific railway in northern Arkansas, occur in a horizontal bedded series of limestone, shale, and sandstone rocks. The genesis of these deposits is similar to that of the well known lead and zinc deposits in Missouri and Wisconsin. They differ from the very important deposits of the Joplin, Missouri, area in being in a rock series older than and underlying the similar beds (Mississippian) in which are found the Joplin orebodies now mined. In this connection, it should be noted that the Joplin deposits are supposed, by some authorities, to have originated in the underlying Cambro-Silurian beds and to have migrated to the overlying Mississippian beds. This relation is presented to show the strength and weakness of popular ideas as to the Arkansas deposits—based on analogy with the Joplin deposits, which are not far away.

The deposits about Zinc are geologically identical with the other zinc deposits in north Arkansas, and are closely similar to the lead and zinc deposits of Greene county, Missouri, and with those of the Wisconsin areas. There is also a less close relation with the important disseminated deposits of southeastern Missouri, but so far as data are available, deposits of the southeastern Missouri type have not been found in the north Arkansas region, although there is a possibility that they may be found in the lower beds.

Source of Lead and Zinc Ores

The ultimate source of the lead and zinc ores of the Mississippi Valley districts was probably in the Cambro-Silurian limestone beds, in which the metals in separate combinations were deposited contemporaneously with the chemical deposition of the limestone from the sea. These metallic minerals were in a very small proportion originally, but, by fairly well understood processes, they have been taken into solution by the underground waters and, through a long period, have been redeposited and concentrated in favorable places, forming the commercial deposits. These facts of the ultimate origin and of the mode of formation offer a sufficient answer to the assertions made by some that these Arkansas deposits necessarily improve with depth, or that they extend indefinitely in depth.

In the North Arkansas field, the existence of a series of faults or displacements, locally called 'breaks,' has provided the suitable combination of conditions for the assembling and deposition of the minerals, and certain facts in relation to these faults are of importance in the theoretical and practical consideration of the deposits. These faults were caused by regional movements or disturbances. In some instances only a crack in the strata is disclosed, while in others there has been a crumpling or an actual vertical displacement of many feet. In the vicinity of Zinc the faults have an approximate northeast-southwest direction. In some instances

the faults only pass through the brittle strata and do not show in the overlying tougher, flexible shale. These faults probably extend laterally for several miles, although they are generally only discernible on the exposed sides of the hills and cannot be traced continuously for long distances, owing to the covering of soil, debris, and vegetation. There are often several of these faults, roughly parallel, with probably also connecting and branching faults.

These faults have formed the favorable physical conditions for the redeposition of the ore, and hence all the deposits in the area have a direct relation with them. The mineral-bearing solutions coming into these fissures laterally, and perhaps from below also, have deposited part of their content as sulphides and as quartz and calcite. Where there was no chemical reaction with the rock itself, then these minerals constitute the filling of the open spaces in the beds forming the brecciated ore sometimes commercially important. When the rock strata were soluble, the walls were replaced in part or wholly by the minerals from the solutions, forming the replacement or 'disseminated' orebodies, which are generally more extensive than the brecciated deposits.

Deposits of Sulphide Ore

The deposits of sulphide ore, when exposed by erosion, are acted upon by the surface waters, producing silicates and carbonates. This oxidation is usually confined to the surface, but in the more open fissures, it extends to depths of 100 ft. or more. This sometimes results in conditions of secondary enrichment. In the district about Zinc, erosion has cut through the practically horizontal beds for upward of 500 ft., leaving elongated, irregular ridges with long, branching, narrow valleys. This affords the opportunity to view directly the vertical succession of the rock strata over a wide area. The tops of the ridges are generally covered with a clay and chert formation of the Mississippian period, from 100 to 300 ft. thick and usually above the 1000-ft. contour. This rock stratum is not mineral-bearing here. Below this are the strata of the Cambro-Silurian which, while varying in thickness in the area visited, are practically continuous, except for the erosion interruptions. Beneath the chert capping is usually found a red limestone, locally known as 'marble,' and still below this a white sandstone of varying thickness. In the shaly limestone below this occurs the first ore horizon, which is usually separated from the second ore horizon by a fine grained, siliceous, brittle, thin-bedded limestone, which grades into shale below. This is followed downward by magnesian limestone with flint, shale, and then a hard crystalline sandstone bed, succeeded by other magnesian limestone beds. These are the lowest beds exposed in the district, but several deep drill-holes are reported to have shown zinc below this fourth ore horizon.

The so-called ore horizons or ore beds represent the intersection of the fault planes with the different strata. The variation of the ore beds and their regular succession throughout the area is consequently characteristic of the rock stratum in which they are. The first ore horizon, usually below the sandstone, but sometimes immediately under the red limestone, is

generally in the form of siliceous replacements of the shaly beds. The ore is disseminated and occurs in successive thin sheets or in a siliceous matrix. There is some lead in places. The bed is missing in some places and is generally only a few feet thick. The second ore bed occurs in a fine grained siliceous banded limestone, the ore forming the cementing material. There is little iron sulphide in this or the first ore horizon. The succeeding ore horizons occur in magnesian limestone beds, and have a tendency toward the replacement type of deposit or occur as veinlets in the shattered brittle beds.

These ore beds are not 'blanket' formations in the commonly accepted meaning. They represent the horizontal widening of the fissures at their intersection with the strata in question. The mineralization presumably does not often extend more than 100 ft. laterally. Where there are several near and parallel fractures, the mineralized rock presents a continuous bed of considerable width. These conditions create a series of orebodies succeeding each other vertically, extending horizontally along the fissures, but not necessarily continuous, and of greatly varying horizontal width. The horizons in which there has been replacement, are the most likely for extensive orebodies. The brecciated ores are sometimes rich, but are not so regular or extensive.

Exploration Methods

The genesis of these orebodies suggests methods for their exploration and development. In most cases, the first and second horizons are exposed on the steep hillsides and can be explored and operated by adits. The other ore horizons must be reached by shafts, from 50 to 150 ft. deep. Exploration can be advantageously carried on by drilling, usually. There are surface indications which are important. 'Silica bars,' so-called, the harder rock along the breaks where silicification has taken place, are noticeable on hillsides and in the valleys. There are also other topographic features, as 'sink holes' and flat, indented slopes, which indicate the presence of the faults and their related orebodies.

Practically all the development about Zinc, so far, has been confined to the two upper ore horizons. The chief ore in the deposits is zincblende, and the mill product contains 64% or more in zinc. There is practically no barite and the lead content is small. Asphaltum shows in the second ore horizon in the Iola mine, in small quantities. There is some iron sulphide in the third and lower ore horizons, but not in large amount. Most of the ore is easy of treatment. In all the deposits are considerable amounts of oxide ores, chiefly zinc silicate, occurring at the outcrop. These are difficult to concentrate satisfactorily and are marketed after hand sorting and at a lower price than the blende. In some of the properties the oxidized ores extend to considerable depth and are mingled with the sulphides, a detrimental factor in treatment. Although development has been carried on for years in this region and a small output of zinc attained, the general results have not been satisfactory, chiefly because of the limits of the size of the individual deposits, so far as exposed, and lack of adequate development and exploration.

Bujun Coal Mine in Manchuria

Translated by REIJI KANDA

The Bujun coal mine is situated in the vast Manchurian plain at the distance of 160 miles from Dairen (Dalny) harbor, near Port Arthur. The mine was first opened by Russians a little before the Russo-Japanese war in 1904. After peace was restored, the right of working this coal mine was transferred to Japan; and since then it has been worked by a Japanese company, Minami Manshu Tetsudo Kabushiki Kaisha, which was organized with the capital of 200,000,000 yen to work the mine and to operate the railroads in Manchuria.

The coal seam lies along the side of a hill which runs along the Konka river. The bed strikes east

by several engineers. Most of them agree in estimating it at 800,000,000 tons. The coal worked since the organization of the Company is as yet only a trifle compared with such a total. The coal mined to the present has been as follows:

	Tons.		Tons.
1907	230,000	1911	1,320,000
1908	490,000	1912	1,470,000
1909	690,000	1913 (est.)	2,000,000
1910	900,000		

The steady increase in the production of coal year after year as shown above is of much interest. The production of coal in Bujun may be expected to continue to increase with the same speed, as the demand is constantly growing. Although the present production of coal at Bujun is small in proportion to the great magnitude and the ease of mining, yet it is large as compared with the production of larger coal mines in Japan. The largest coal mine in Japan, Miike in Kyushu, produced 2,050,000 tons in 1912, which is nearly the same quantity as the estimated output of Bujun in 1913. The total production of all coal mines in Hokkaido does not amount to more than 2,000,000 tons per year. Bujun coal can be worked for perhaps 300 years in the future, and the right of working this is considered to be a notable addition to the wealth of the Empire.

Ore Crushing Underground

The Witwatersrand Gold Mining Co. has recently inaugurated a system of underground ore crushing. On the fourteenth level a jaw breaker has been installed, and the results secured are stated to be thoroughly satisfactory. In order to economize with native labor and to dispense with 'boys' hitherto engaged in breaking up these large rocks and to render them available for other work, a rock-crusher has been installed, the discharge from which is fed direct into the shaft bins. This is the first rock-crusher to be employed underground in South Africa and its installation at the Knights mine may lead to adoption of the system at other mines along the Main Reef series. Underground rock-breaking is practised in other mining fields. In the Round Mountain Mining Co.'s mine, at Round Mountain, Nevada, are two crusher stations. During the year 1912-13 the following work was done: No. 1 produced 6382 tons of \$4.69 ore, and 16,306 tons of waste worth 77c. per ton; while No. 2 produced 15,590 tons of \$7.12 ore, and 40,589 tons of waste worth 97c. per ton. The cost of crushing, screening, and transport, including repairs, was 5 to 6c. per ton. Fear has been expressed that the running of crushers underground might have a deleterious effect on mine atmosphere. Inquiries have been made regarding the effect of underground crushing on mine atmosphere at the Knights, and it has been found that the breaker is giving no trouble in this respect whatever. The crusher station is surrounded by atomizers, and the amount of dust created is said to be infinitesimal. Having regard to this testimony, it seems by no means unlikely that the system will be extended to other mines along the Rand.—*South African Mining Journal*.

MAP SHOWING ORE DEPOSITS OF MANCHURIA.

to west, and may be followed along the onterop for the distance of some eight miles. The hills in which the coal occurs rise abruptly from the great plain of Manchuria, 100 to 300 ft. The thickness of the coal is tremendous, averaging 130 ft. The bed dips toward north at an angle of 20 to 30°, and extends under the Konka river. In the beginning the post and stall system was used and only one-tenth or less of the whole thickness of the bed was mined. As this involves much loss, much attention has been paid to finding a better system of working. Sand-filling was first tried on a large scale in 1911, with the expenditure of 300,000 yen. This system was found to be the one best fitted to working this large seam, and it was determined to adopt it exclusively in mining the Bujun coal. It has been found that by this system 85% of the entire coal can be won. The sand is obtained near by in the Konka river in any required amount. The quality is first class, it consisting of fine sand with no large gravel. As the sand is constantly coming down after every heavy rainfall, there is no fear of exhaustion of the supply.

The quantity of coal existing has been calculated

Work of the Oriental Consolidated Mines

By ALF WELHAVEN

The total receipts of the Oriental Consolidated Mining Company, operating in the Unsan district of Korea, for the year ended June 30, 1913, were \$1,661,476.29. The total operating costs for the year were \$1,016,778.22, leaving an operating profit of \$644,698.07. New constructions, development work, etc., absorbed \$73,313.98, leaving the net earning of \$571,384.09. The average value of the ore was better than during the previous year, but the heavier mining costs, higher concentrate treatment costs, and larger construction expenses materially re-

Ore Reserves

The estimated ore reserves July 1, 1913, were:

	Tonnage.	Value.
Tabowie	470,000	\$2,850,000
Taracol	260,000	1,185,000
Chintui	17,400	67,875
Kuk San Dong	16,200	47,825
Charabowle	38,600	301,100
East Candlestick	3,700	37,000
Total	805,900	\$4,488,800

In the active mines 33,248 ft. of development

TABOWIE MILL.

duced the net profit. The mines yielded 312,818 tons of ore worth \$2,000,787, as follows:

	Tonnage.	Value per ton.
Tabowie	112,529	\$7.18
Taracol	93,558	6.03
Chintui	28,487	4.18
Kuk San Dong North.....	12,757	3.92
Kuk San Dong South.....	13,774	2.72
Kuk San Dong Central.....	606	4.20
Kuk San Dong Kisen.....	6,986	3.63
Charabowle	37,658	8.65
Candlestick	6,463	10.61
Trlbut mines produced	883	5.30

Total mining operations 313,701 \$6.39

This was mined at a cost of \$1.95 per ton, including cost of all underground development work done at these mines during the year. The mining cost was 33c. per ton higher than last year, on a smaller tonnage, since 6889 ft. more development work was done this year. It is also necessary to pay Korean miners more for their work, because the cost of living has increased. It is now costing a Korean twice as much to live as it did 5 years ago, and four times as much as it did 15 years ago, on account of the advance in price of rice and millet. In addition, the Charabowle mine flood increased the mining cost for the year by \$33,270.94.

*From annual report as general manager for the Oriental Consolidated Mining Company.

work was done during the year and 1534 ft. of development work was done in prospecting outside.

The past year's work has shown that the Tabowie mine ore reserve on July 1, 1912, was underestimated by approximately 53,000 tons and \$397,000 in total value. The new ore developed during the year was 139,529 tons at \$7.75, or \$1,080,825, and the estimated ore reserve July 1, 1913, was 470,000 tons at \$6.06, or \$2,850,000 as total. In the Taracol mine the new ore developed during the year amounted to 96,558 tons at \$6, or \$579,436, and the estimated ore reserve July 1, 1913, was 260,000 tons at \$4.56, or a total of \$1,185,000. The new ore developed during the year in the Chintui mine amounted to 22,887 tons at \$4.14, or \$94,745, and the estimated ore reserve, July 1, 1913, amounted to 17,400 tons at \$3.90, corresponding to \$67,875. In the Kuk San Dong mine on July 1, 1913, the estimated ore reserve was 16,200 tons at \$2.95, or \$47,825, the new ore developed during the year being 23,323 tons at \$4.12, or \$96,058.95, and the ore mined and milled during the year having been 34,123 tons at \$3.38, or \$115,234. The tonnage milled at Kuk San Dong during the year was small, because it was more profitable to sort the ore and run only 20 of the 40 stamps. The estimated ore reserve at the Charabowle mine on July 1, 1913, was 38,600 tons at \$7.80, or \$301,100. The result of

the Charabowie development work, 42,258 tons worth \$395,973, was more encouraging and satisfactory. Work during the past year was handicapped by the heavy inflow of water from the river. This has been confined to the south end of the mine and above No. 1 level, but it has been impossible, up to the present, to stop the river water from entering the mine. For this reason the cost of fuel for pumping and hoisting amounted to 45% of the total

TARACOL HEAD-FRAME.

expense. The estimated ore reserve in the East Candlestick mine was 3700 tons at \$10, or \$37,000, on July 1, 1913.

Prospecting Work

In the West Candlestick prospect the old lower adit was advanced 79 ft. on 10 in. of \$4 ore and is now in 1350 ft. There was expended \$1693 for taxes and development work on the Chosen district claims, but nothing of value was found. Work on the old abandoned Tong Koll mine was continued during the year, but not much was done, owing to the lack of machinery. As soon as the other mines commence operations by electric power there will be available boilers, hoists, and pumps for carrying on the work at Tong Koll. The old abandoned Chitaballie mine was again turned over to the Koreans to work on a royalty basis and a revenue of \$180 was received as royalty. During the past year Korean tributors delivered at the Taracol mill from tribute mines 883 tons of ore worth \$4675.50, for which they were paid \$1839.79. The net profit on this ore was \$1061.32. All of the tribute ore came from small veins which the Company could not work at a profit. As the Korean prospectors are now working under more favorable conditions, several hundred men are engaged in this work and many new prospects have been found. Development work done by these prospectors on the Sambong vein indicates that the Company may be able to commence regular operations there.

Milling

During the year 313,701 tons of ore worth \$2,005,463 was crushed in the Company's mills. Of this gold, 89.4% was saved in bullion and concentrate, and 10.6% was lost in the tailing. Milling expenses for the year were \$168,657.32 or \$0.54 per ton, 4c. more per ton than the previous year. This increase was due to the heavier cost of motive power. The

crushing capacity was reduced, because only 20 of the 40 stamps at Kuk San Dong were at work, and time was lost at Tabowie on account of shortage of water during the winter months, as well as at Candlestick owing to lack of miners. At the Taracol tube-mill plant a total of 25,319 tons with a value of \$675,656 was treated. The bullion secured was \$571,970, corresponding to 84.7% extraction. Although the percentage of extraction is slightly better than that obtained during the previous year by leaching, the tube-mill plant is, up to now, a failure economically, because the extra cost of treatment amounts to more than the gain in extraction. The staff is working toward an increase in the extraction by improving the classification, grinding, and agitation, and the operating expenses will be reduced by the use of electric power instead of steam. At the Kuk San Dong cyanide plant the extraction was 15% higher than last year and the cost of treatment \$1.68 per ton lower.

Kuk San Dong Dump Re-Treatment Plant

The operations at the plant yielded \$70,642.73; a 70% extraction. The cost of treatment at this plant was \$2.39 per ton, or materially more than last year. The plant ran successfully and made a profit of \$27,822.63, which has been credited to the cost of the plant, because the expenses of this construction were charged against the dump. There still remains \$10,749.03 to be earned before the plant has entirely paid for itself. During the coming year the plant is expected to yield a good net profit. The cost of treatment at the Candlestick cyanide plant was \$1.18 per ton, or \$0.30 per ton more than the previous year, due to lower tonnage and the

A GROUP OF MINERS.

higher cost of fuel. A total of 6511 tons was treated, yielding \$10,276, or a 52.9% extraction.

Construction Work

In order to insure sufficient water for the Taracol plants, a pumping plant has been built on the Pukchin river, consisting of boiler and pump, which delivers the water through a pipe-line one mile long against a 400-ft. head. During the coming winter electric power will be used for this pumping plant. The expenditures to date are \$8074.61. As the Maibong, Taracol, and Tabowie camps in future will be operated by electricity, the staff has been busy

during the year in remodeling the existing machinery and installing new equipment where needed. Brick and iron sub-stations have been built at Maibong camp, Taracol mill, Taracol mine, and at Tabowie camp. The steam hoists at Tabowie and Taracol mines have been converted to electric drive, and a new electric cage hoist has been installed at the Taracol mine. A new electric hoist has been erected at the Charabowie mine, as well as three smaller electric hoists underground at Charabowie and Tabowie.

Iron-armored lead-covered electric conduit cables have been installed in the Tabowie, Taracol, and Charabowie mines to transmit current to all underground electric machinery. Electrically-driven centrifugal and plunger pumps have been placed in these mines. Induction motors have been installed for the Taracol tube-mill plant, the Taracol mine compressor, and the Maibong mill. A small auxiliary steam-driven electric plant has been built at

department \$2628.16 was expended during the year.

Electric Water-Power Plant

The operating expenses of the electric power-plant for the year were \$16,262.37, which includes a considerable amount of work on the flumes and ditches in order to keep them in proper working condition. A great deal of construction work was done in the electric department this year, in anticipation of the electric power to be delivered by the power-plant under construction by Okura & Co. at Ansha. The rainfall in 1912 was 51 $\frac{3}{8}$ in., and during 1913 was 48 $\frac{3}{16}$ inches.

General

Gold bullion amounting to \$1,705,497.75 was sent to the Imperial Japanese mint at Osaka at a cost of \$6761.86. The bullion was shipped over the government railways and handled by the Bank of Chosen, Ltd. The medical staff treated 29,345 cases at the Taracol hospital during the year; 13,448 cases were Company employees. No charge of any kind is made at the hospital, and people come from far and near to receive the benefits of this free medical service, on which there was expended \$8867.89 during the year. On Christmas Day, 1912, the management was authorized by the president of the Company to distribute \$10,000 among the foreign employees, on a percentage basis, the older employees receiving the greater benefit. This is the eighth consecutive Christmas that \$10,000 has been distributed. It was very pleasant to make this distribution, as the men had rendered very satisfactory services, and the management takes this opportunity to express its appreciation of the loyalty and coöperation shown by its employees during the year.

Sulphur in Louisiana

In one respect Louisiana stands preëminently in the lead of the states of the Union; that is, in the production of sulphur. In 1904 the Frasch process for the recovery of sulphur from beds underlying a heavy cover of quicksand was put into operation by the Union Sulphur Co., of Sulphur City, near Lake Charles, in Calcasieu Parish. Since that time approximately 2,330,000 tons of refined sulphur has been recovered from the Louisiana deposits. Prior to 1904 the only domestic source of sulphur in quantity in the United States was pyrite, from which sulphuric acid is made direct, and nearly all of the sulphur used was imported from Sicily. At the present time the domestic output of refined sulphur, except from Louisiana, is a negligible quantity, and the quantity and value of the imports are insignificant compared with what they were ten years ago. In 1903, one year before the production of sulphur in Louisiana began to exert an influence upon the market, the imports of sulphur into the United States amounted to 191,033 long tons, valued at \$3,709,690. In 1912 the imports were 29,927 tons, valued at \$583,974. On the other hand, the domestic production of sulphur in 1912, according to the U. S. Geological Survey, exceeded by more than 145,000 tons, or nearly 50%, the imports of Sicilian sulphur in 1903 and was more than ten times the imports of sulphur in 1912.

HAULING TIMBERS.

Maibong, to run the mine pumps there in case of interruption in the electric power-supply from Okura & Co. The spare water-power plant 500-kw. generator, which has been in stock for several years, has been brought to Taracol and will be connected to the mill engine to provide an auxiliary plant there. The electrification of the three mines is now practically finished and the total expenditure to date is \$62,304.46.

Timber Supply

On cordwood railways some \$41,000 was expended during the year, including \$12,500 for a reforestation tax imposed by the government on the wood company, which, in turn, reimbursed itself by selling cordwood, timber, lumber, and charcoal to the mines and mills at an increased cost. The wood company did good work during the year, furnishing 27,827 cords of wood, 159,697 mining timbers, 57,539 pieces of lumber, and 5644 boxes of charcoal for Tabowie and Taracol. On the advice of the Governor General of Chosen the Company has commenced tree planting here. The government aided in securing the services of Kosaburo Matsushita, a forestry expert, who has charge of the reforestation work. This spring 30,000 acacia trees were planted and nurseries for 120,000 seedlings were established. All of these are growing well. The Company has applied to the government for permission to plant trees on certain hills, near Tabowie, and it is the intention to plant 100,000 trees next year. In this

Selective Mining in the Gold Fields Mines

By H. H. WEBB

*The term 'selective mining' is capable of more than one interpretation. The first inference conveyed is that of robbing the mine of its highest or best grade of ore; or it may be taken to mean stoping from the ore reserves of the mine a more or less higher grade of ore than the general profitable average of those ore reserves call for or would appear to indicate as good mining under existing conditions. Such a policy may be dictated by financial reasons or obligations or a desire to give present shareholders the benefit of higher returns, leaving poorer ore to be extracted at some future time, when it is hoped working costs and conditions will be more favorable. There can, I think, be no doubt that, from a purely mining point of view, the policy governing mining operations should be the extraction of the total ultimate values from the profitable rock which a given area or block of ground contains at the lowest average cost without being influenced by higher temporary dividends or share values, and a group or mine following this policy could hardly be accused of selective mining even if at times it was necessary to draw upon higher grade ore reserves than the average to bridge over a temporary period of depression in development or a momentary advance in working costs, or to maintain a fair profit while completing the necessary extraction of low-grade but profitable ore from old abandoned or caving stopes.

Choice of Policy

If a mine on the Rand could be developed to its boundaries and thoroughly equipped before milling operations began, something in the nature of a definite policy could be laid down at the start and followed more or less closely, subject, of course, to varying local factors. But since this is impossible, any policy adopted by a group or by a mine may at times have to be varied or modified, and there are no mines worked which I know of, particularly some classes of low-grade gold mines, in which at times a process of selection is not necessary, and this applies more or less to all the mines on the Rand, and particularly on occasions to some of our lowest grade ones. At such mines there are at times large blocks of ground being attacked which, as stoping proceeds, vary in value, and where the margin of profit is small and where a small and possibly temporary variation may affect the profit of these blocks for the time being. In such cases it is often necessary to draw upon the higher grade sections of the mine to maintain the regular monthly profits until an improvement, as work progresses, takes place, although the general policy or effort may be to mine as nearly as possible the general average of the ore reserves or that indicated as profitable for the mine as a whole; but it should be understood that while mining from reserve ore of average value the mill grade will be somewhat depreciated, due to the inclusion of low-

grade ore from other sources such as reclamation and development faeces.

Development Problems

It can be readily understood that one of the most important factors affecting the working of each individual mine is the extent and the value of the tonnage kept well developed ahead of the requirements of the reduction plant. Where the average value of this is maintained over large areas and great tonnages, the best policy for working each individual mine is not difficult to lay down and carry out; but when the average grade is slowly falling as additional depth is reached, the difficulties of policy and management are increased. And there can be no doubt that from our experience and in our mines the average value of the ore developed over large areas has been getting lower as greater depth is attained. High-grade areas and patches are found in depth, but these are not as frequent or extensive, nor are they in all cases as high in value as they were nearer the outcrop, consequently the general average over large areas has fallen. True, there are more favored parts of the Rand formation than others, in which the average values in depth are better maintained. But in those parts not so favored the serious question of meeting lowering grade becomes one of working costs, and these, with good management, can best be met by increasing the crushing and treatment and mining capacity, consistent with the existing lay-out as well as the life of each mine. The erection of large plants and the increasing of the capacity of smaller existing ones, resulting in lower operating costs from increased scale of working, has generally been accounted the cause of the lowering of the average grade of the ore sent to the mill, and this has been so in some cases, affording an opportunity to extend the life of the mine by lowering the working limit of its profitable ore. But there are mines on the Rand at which the lowering of working costs has been a necessity to meet the lowering grade of the ore developed, and under this latter heading may be classed such of our mines as the Knights Deep, Simmer Deep, and Jupiter, and this necessity, which through strenuous efforts has brought about working economies, has served to set an example through these mines of what might be accomplished by other more favored ones.

A lowering in average grade of the ore does not necessarily mean a diminution in output or dividends, but it does mean working on a larger scale to maintain them, coupled with close management and low costs, which, besides bringing this low-grade ore within the margin of profitability, also secure increased profit from the better grade of ore formerly constituting the reserve as well as from the excess tonnage treated. Some of the largest and best paying mines in the world are of very low grade, but conditions are favorable for low costs, wholesale mining, and large tonnage.

*From report as consulting engineer to the Consolidated Gold Fields of South Africa.

Fixed Costs

One cannot always take the nominal working costs on a mine as a limit of profit of all of the ore exposed in that mine. There are certain fixed charges on all mines which, as a whole, are not largely affected by the scale of working on the mine, but which, as they appear in the working costs, increase or decrease per ton, depending on the scale of operations; while the reduction plant and certain other charges are not only as a whole affected by the scale of operations, but are also lower per ton on account of the increased tonnage treated. But underground mining, especially as regards breaking costs per ton, is affected by local conditions, especially at the points of attack. Ore having a value even below the nominal or average costs of the mine may, due to favorable local conditions, easily pay to break and send to the mill, and in dealing with each of our mines an endeavor has been made to give attention to this. In going over the records of the mines of the Gold Fields group (excluding Sub Nigel) for the past three years, I find that there were some 563,000 more tons milled in 1912 than in 1910, that the average recovery had fallen off during the three years by 2s.7d. per ton, even though the percentage of extraction had gone up somewhat, and comparing the average working costs of the three months, January, February, and March, 1910, with the corresponding period of 1913, a reduction of 1s.0.9d. per ton milled, equivalent to a total of £55,600 from the tonnage treated, has been effected during the latter period. To one knowing our mines, all of this points to an effort during this period to work the mines of the group as nearly as possible for the average value which the profitable ore reserves of each indicated, as well as to a falling off in grade of all of them, noticeably Knights Deep, Simmer East, Simmer Deep, and Jupiter, and this has been the case.

Decline in Grade of Ore with Depth

This fall in average grade with depth at the individual mines has been shown to be true, not only by the screen samples of the ore milled and by the recovery value per ton, but by the careful sampling and assaying of level by level in each mine as greater depth was reached, by careful sampling of stopes on each level sending ore to the mill, and by the yearly re-cast of the ore reserves in each mine. The question of the profit by sorting has been gone into thoroughly during the past year by the engineering staff, particularly as to the advantages at our low-grade mines, where sorting has been estimated at 10% and under. At these it has been found that the tendency was inadvertently to estimate too high a percentage as sorted out, and on these low-grade mines at this low rate of sorting the advantages to be gained by sorting have been found to be very doubtful, and as a matter of fact there is a slight margin of profit in favor of not sorting when large tonnages are handled.

The value of Ohio's mineral production in 1912 was \$111,229,656, an increase of \$14,139,372 over 1911. Ohio is the premier state of the Union in the manufacture of clay products and the grindstones and pulpstones, according to a summary of

mineral production compiled by Edward W. Parker, of the U. S. Geological Survey. It is second in the production of pig iron, bromine, and lime, but is of no importance as a producer of iron ore. It is third in the value of its output of natural gas, salt, sand and gravel, and gypsum.

Design for an Air-Lift

R. H. SHAW

*The sketch below is a suggestion for the construction of air-lifts for use in elevating pulp in cyanide plants. This design has been used at the Colburn-Ajax mill for some time past, and has proved satisfactory in every way.

In raising pulp by means of air-lifts, one encounters the problems of broken compressors, chips of wood, pieces of belt, and numerous other things, which, with almost human maliciousness, find their way into the pipes. These cause chokes which are difficult to loosen and may cause serious delay. The design given is made with the object of accessibility and rapidity in removing chokes.

In case of a choke, the plug on the bottom of the tee is removed. This drains the stand-pipe and lift-

CROSS-SECTION OF AIR-LIFT.

pipe, and usually cleans out everything except the air line. Next the union on the air line is disconnected and the other plug, together with the horizontal nipple, is removed from the tee. The horizontal nipple is screwed into the elbow (marked 1) loosely, so that it readily comes apart at that point while the plug is being unscrewed. All the pipes now can easily be cleaned of sand or slime.

To replace the parts the vertical nipple and elbow (marked 1) must be held in place through the bottom of the tee and the air pipe screwed in at the same time as the plug in the side of the tee is replaced. The bottom plug is then put back into place and the lift is again ready to operate. The maximum time usually required for this complete operation is about ten minutes. The loss of pulp and solution is negligible compared to the time saved.

This construction requires the lift to be at least one foot above the floor and supported from clamps around the pipe. Ordinarily, both of these details are readily accomplished.

*From Colorado School of Mines Magazine.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Revision of United States Mining Laws

The Editor:

Sir—I have followed with much interest the discussion on the question of the revision of the United States mining laws contained in the October 18 and October 25 issues of the *Mining and Scientific Press*. The article by Russell L. Dunn is so clear, so logical, so true to the facts that some one ought to be generous enough to publish and distribute it *gratis* to everyone who is interested in mining. He leaves little to be said, and his arguments the opposition, so far, have not seen fit or have not been able to answer. Following closely after Mr. Dunn's article comes the contribution from the pen of George Otis Smith, Director of the U. S. Geological Survey, and, while in no way an attempt to answer the arguments of Mr. Dunn, still the main points of the revisionists are probably as well presented as they can be, so that a little more detailed study of Mr. Smith's article is in order.

To begin with, Mr. Smith starts out by saying: "Whatever the forum selected, public discussion in America tends to evoke more language than ideas." True, and generally admitted. Then he goes on to say: "Plain ideas are dressed up in borrowed or imported finery with all the tender care that a fond mother lavishes upon her little girl going to a first party, so that too often the practical man who knows the workaday world at first hand delivers an address conspicuous for the elegant words which completely envelop and conceal plain facts and solid opinions that deserve more appropriate treatment." I confess that Mr. Smith's meaning is not entirely clear to me in this sentence. Granting that we may be allowed to apply the adjective "elegant" to words, I am still unable to understand why inelegant words should always be selected in speaking of and discussing even plain subjects. Again, I do not think that Mr. Smith's implied charge is altogether warranted, if he means that it is usually the practical, hard-headed, work-a-day man who is guilty of speaking in hyperbole or high-flown language when making a public address. It has been my experience that if the practical man has anything to communicate, publicly or otherwise, he is able to do so in a simple, straightforward, convincing way. On the contrary, the man who has not much to say, owing to ignorance and other defects, but who wishes to make a big noise and a good impression, is the man who makes liberal use of high-sounding terms and who is able to envelop his few ideas in an impenetrable fog of words.

Continuing, he says: "To consider now perhaps the most important matter in which this body is particularly interested, namely, the federal legislation needed to promote mining on public lands, it

is imperative to recognize certain ideas that have won large popular support, if not adopted by the majority, especially as these ideas have never been written into our archaic mining laws." Here again I must confess that the author's meaning is not entirely clear to me. If this is a government wherein the majorities rule, why, may we ask, should these ideas be adopted? Following this, our author proceeds to lay down some of these "ideas," after first, however, raising them to the dignity of "principles." These "principles" that the future mining and business man will have to sustain and guide him will be: "Big business more than small is in need of strong control by the people; the day of big business, in the sense of unnatural and unrestrained monopoly and special privilege is passing; (where, may I humbly ask, does it now flourish?) effective inspection and intelligent regulation by the people's representatives will increase; the bright light of publicity should and will shine (possibly the muck rake, too, will be in evidence, although Mr. Smith did not mention it) on the inner workings of all private business which either touches or controls the production and distribution of the necessities of life. * * * All of these propositions must, I believe, be accepted as premises in the formulation of any new mining statutes whose purpose it is to provide at all adequately for the present and future."

So here we have the case clearly stated. These "principles" must be the foundation upon which all new legislation must be framed. Can we at first sight appreciate fully the significance and far-reaching influence of legislation based upon such "principles"? When we include, as Mr. Smith does, all industries having to do with the "production and distribution of the necessities of life," we include not only all industries based directly upon mining, but also all agricultural, manufacturing, and transportation enterprises; in fact, everything. All private enterprises are to be turned inside out, in order that "the bright light of publicity may shine" upon the interior workings, and all private business will cease to exist, and what is now one man's business will become everybody's business. Each and all of us will then be compelled to turn to this infinitely exalted, infinitely magnified government from whence comes all sustenance, all life, all intelligence.

Following this course of reasoning, it is easy to see why Mr. Smith advocates all the measures he does; why he advocates leasing instead of selling the land. Some of the reasons he advances to justify this change are amusing, as where he says: "A large burden which the mining industry now has to bear * * * is made up of the various risks and uncertainties which attend it. * * * For this reason, in order to lower the cost of coal, I favor a leasing, rather than the present method of selling government coal lands at an appraised valuation." He therefore admits that the present system, which his bureau strongly advocated and finally put into operation, has been one of the causes for the increased price of coal. Evidently the methods of appraisal have been at fault, and the arbitrary valuations placed upon such lands have resulted in

raising the price of the product. But did this objection have any force when the old system of disposing of government coal land at only a nominal value made that charge only a nominal one? No. Is it going to be possible for the government to appraise the value of a tract of land for leasing purposes any more accurately than where it is appraising the same tract for sale? Certainly not. The framers of our old mining statutes were thoroughly cognizant of all these points that Mr. Smith is at such pains to mention, and because they did clearly perceive all the hazards and risks incident to mining they endeavored to minimize all the artificial ones by (1) charging the miner only a nominal price for the land itself, and (2) granting to him a title in fee simple so that his interest in that land would be of the most intimate and lasting character. Mr. Smith would lead us to believe that by substituting the leasing system for the old, the consumer will be relieved from having to pay the increased risk attached to mining enterprises, as he says: "Any scheme of selling an undeveloped resource involves uncertainties in valuation, and the risk thus created is liberally discounted by the operator * * * but the public pays the bill." Who is going to pay the bill under the leasing system? The same public, of course, only it will be a bigger one.

Our author professes to believe that the important ends to be gained by new legislation along his proposed lines will be "to promote mining on public lands." That is a specious plea, indeed, and one that is always made; but how can anyone make it without ignoring entirely the history of our wonderful mining development? Under the system of mining laws, in the brief period from 1800 to 1907, the value of our mineral products increased from \$364,928,000 to \$2,071,613,000, or about 5.6 times, while in the same period our population increased only from about 50,000,000 to 90,000,000, or about 1.8 times. Our mineral production, therefore, during this period increased about 3.1 times faster than the increase in population. And it is fair to remark that the increased value of our mineral products has not been gained at the expense of an increase in cost per unit, but in most cases has actually been marked by a decrease in cost, so that quantitatively our mineral production has been even greater than shown above. Does this show that there is any alarming or pressing need for a profound revision of our mining laws? Hardly.

I believe that every careful thinker will admit that the mining enterprises of this country, and especially in the mining states of the West, have stimulated, more than any other enterprise, the rapid and wonderful development of that region. It was the mines and mineral fields that first coaxed the railroads to extend their slender tentacles over hundreds and even thousands of miles of wilderness between. Now are we to lightly discard a system of laws which has been of such vast benefit to our country and substitute for it one which is still untried, and in its very spirit absolutely opposed to the principles and traditions of our nation? Are the people of this country going to voluntarily subscribe to a system of laws that takes from them

and from their children forever all hope of securing right or title to any part of the mineral resources of the country? Why extend the privilege to the farmer and deny it to the miner? Why should the consumer be saddled with a government fee for a leasehold, when he knows that all such sums paid in merely goes to pay the salaries and expenses of the collecting agencies? Even if our benevolent purposes were to provide for futurity (as seems to be the underlying motive of most government-ownership advocates), it is difficult to see how the system of leasehold is going to secure these benefits to posterity when all sums thus collected are immediately paid out to keep alive a government bureau. If, as our author states, there has been any widespread demand for "federal legislation to promote mining," it has only been in very recent years and coeval with that period when the government itself, and its various and numerous bureaus, have shown the greatest desire to interfere in all kinds of mining and other industrial enterprises. The clamor for new and more legislation to correct usually some fancied wrong is, as your correspondent, Mr. Dunn, so aptly remarks, "the easy political first-aid device for the politically shiftless." Mining and other enterprises in this country do not stand in need of any more new legislation nearly so much as they do of protection from all sorts of useless and pernicious governmental exactions and interference. Physicians long ago learned that in order to revive the ebbing strength of a patient, copious blood-letting was not always the best measure; and so, possibly, those who are charged with attending to the business of the government may learn from this that frequent and copious draughts from its industrial patients is not always best for their health.

Admitting the fact that we live in a period when legislative shifts and changes are the order of the day; when the multitude are always willing to discard anything because it happens to be old; when quacks and quackery of all kinds enjoy a larger and more influential following than ever before; when everything seems to be in a condition of a flux and change and nothing seems fixed; still let us hesitate, let us deliberate, and study long and carefully, before we decide to cast our old mining code into the scrap heap, and blindly accept in its stead something that has only its novelty to commend it.

ROYAL P. JARVIS.

Knoxville, Tennessee, November 4.

[We asked for the opinions of opponents as well as the advocates of the changes proposed, and Mr. Jarvis has been good enough to state the reasons for the faith that is in him. Passing the persiflage directed at Mr. Smith's introduction, for the Director of the Survey is abundantly able to hold his own in any such contest of wits, Mr. Jarvis' main arguments seem to be that the old plan has in fact promoted development and any leasing system (assuming that a change in the mining laws involves its introduction) would unfairly penalize the mines. As to the first, it will be admitted by all that the liberal laws and more than liberal interpretation of them has promoted rapid development of mining in

our West. To hold, however, that no other system would have done as well, or would do better now, is to shut one's eyes to the history of other countries and even to parts of our own country where development has been equally as rapid though based on other systems. No one wants to check mining or increase its risks. What is wanted is to prevent grabbing of public land by speculators who withhold it from development, and to decrease litigation. With these two impediments minimized, the government will have taken a long step in the right direction. Both these have been accomplished, and are being accomplished, where the system of tenure

Stirling v. Babcock & Willcox Boilers

The Editor:

Sir—The article on ‘Waste Heat Boilers in Reverberatory Furnace Flues,’ which you published in the October 11 issue, is a very interesting example of partly calculated data. Mr. Sorensen has shown clearly that a battery of 520 hp. will save, or lose, more money than one of 375 hp. An analysis of his own figures will, however, disprove some of his conclusions.

The following ‘per horsepower’ figures are taken out with a 5-in. slide rule and so I do not claim great accuracy:

	Babcock.		Stirling.	
	Total.	Per hp.	Total.	Per hp.
Average boiler horse-power	520.00	375.00
Number of boiler repairs	11.00	0.02	23.00	0.06
Average cost of repairs, and cleaning and repair, per repair, total, dollars	172.17	0.33	95.34	0.25
Repair cost per 100 days, dollars	189.39	0.36	100.69	0.27
Water evaporated by battery of two boilers per day, lb....	861,111.00	1,660.00	621,472.00	1,660.00
Water evaporated in 100 days, less days lost cleaning and repairing, pounds	78,998,598.00	152,000.00	57,840,429.00	157,000.00
Evaporation lost during cleaning and repairs, pounds.....	7,112,802.00	13,700.00	4,306,803.00	11,500.00
Equivalent oil recovered, dollars	27,708.00	53.50	21,785.00	58.00
Equivalent oil lost, dollars	2,494.00	4.80	1,512.00	4.05
Cost of cleaning and repairs per 100 days, dollars.....	189.39	0.36	100.69	0.27
Total lost and cost per 100 days, dollars	2,683.39	5.18	1,612.69	4.30
Net recovery in 100 days, dollars	25,024.61	48.00	20,172.31	54.00
Balance in favor of the Stirling type per hp. per 100 days..	6.00
In favor of Stirling per horse-power year.....	22.00

is different from our own.

In the matter of fee titles versus leases, Mr. Jarvis asks, “Why extend the privilege to the farmer and deny it to the miner?” We are tempted to direct the printer to set the reply in large black type, since the answer has so often been given without seeming to have attracted the notice of the protestants. A farm is permanent, a mine is not. When a farm is brought under cultivation, a productive industry and a family is added to a community for all time. The farmer takes an annual return from the ground without necessarily decreasing the capital involved. The mine brings in a temporary population and the miner takes out ore once for all. His annual ‘profit’ is really a division of capital. It is possible to assess the farmer his share of general expense by taking a part of his crop, which is what taxation does. It is impossible to do the same with the miners except on a basis of tonnage tax, which amounts to a royalty. If farming necessarily involved permanent destruction of land, we think it would quickly be found that public opinion would prevent free giving of land for all time to whoever asked. The farmer would be held to strict accountability. He would be required to use the land only on terms dictated by the general public for the general good. This is all that it has been proposed to ask of the miner; to reserve a measure of control while he exercises rights delegated to him by the people as a whole. It is this difference between disposition of income and of capital, that warrants a different system of tenure and taxation. In fairness to others less radical than ourselves, however, it should be stated that the revision proposed does not necessarily involve going over to a leasehold basis.—EDITOR.]

The Stirling boilers needed many repairs compared with the others; it seems to be their only weak point, and, judging from my memory of the work at Anaconda, Montana, it seems abnormal. Unfortunately, the first cost of the two batteries of boilers, as installed, is not given, so no comparison can be made of the cost of the power obtained upon a correct basis. Mr. Sorensen, however, concludes with a balance of \$17,710.90 in favor of the Babcock boiler. This divided by 520 gives a profit of \$34.20 per horsepower-year. My analysis indicates that the Stirling boiler is worth about \$22 per horsepower-year more than the Babcock. The difference is large and is worth attention.

The Stirling is apparently a much smaller boiler than the other. Probably the flue gases in the down-take behind the Stirling are much hotter than behind the Babcock, showing that a larger boiler could be used.

HERVEY GULICK.

Los Angeles, October 18.

A chronological list of the more disastrous coal-mine accidents in the United States shows that 275 accidents have occurred since 1839, in which five or more men were killed at one time, representing a total of 6777 fatalities. Of these accidents, there were 135 that killed from 5 to 9 men each, a total of 859; 82 that killed from 10 to 24 men each, a total of 1237; 25 that killed from 25 to 49 men each, a total of 870; 18 that killed from 50 to 99 men each, a total of 1221; 11 that killed from 100 to 199 men each, a total of 1534; three that killed from 200 to 299 men each, a total of 695; and one that killed 361 men. Of these larger disasters, gas and coal-dust explosions caused 183 accidents and 5111 deaths.

Special Correspondence

NEW YORK

ZINC METALLURGY DISCUSSED BY A. I. M. E. AND AMERICAN ELECTROCHEMICAL SOCIETY.—CONTINUOUS FURNACE IN SIGHT.—FLOTATION AND THE M. & M. SOCIETY.—SMELTING FLOTATION CONCENTRATE.—GOLD MEDAL AWARDED MR. AND MRS. H. C. HOOVER.

The November meeting of the New York Section of the American Institute of Mining Engineers, held in the United Engineering Societies building on November 20, was a joint meeting with the American Electrochemical Society. The topic of discussion was the present status of the metallurgy of zinc. Lawrence Addicks presided and the first paper was by George C. Stone, metallurgist for the New Jersey Zinc Co., who briefly summarized the limitations imposed on zinc metallurgy through the fact that zinc oxide is only reduced by carbon at a temperature above the boiling point of zinc, so that the metal must be produced as a vapor. This vapor is easily oxidized by contact with oxygen or CO₂, so that its condensation can only be done in a reducing atmosphere, and within certain limits of temperature in order to obtain a commercial product. Within the bounds imposed by these peculiarities, much progress has been made; the amount of fuel required has been greatly reduced, the life of the retorts has been doubled, and the labor necessary has been greatly decreased as compared with earlier practice. The chief possibilities of further progress seem to lie in increasing fuel economy through decreased radiation losses and otherwise, further decreases in the amount of labor required, and a general lowering of costs through the better design of plants in the light of experience. He was followed by W. R. Ingalls, who discussed the possibilities of the electric smelting of zinc, concluding that as yet experimental work in this line has not progressed to a stage where its success can be confidently predicted. Electrolytic refining of zinc was to have been discussed by Victor Engelhardt, chief engineer of the Siemens-Halske Co., but in his absence the topic was taken up by J. W. Richards, professor of metallurgy at Lehigh University, who read an abstract of an earlier paper on the subject by Mr. Engelhardt and interestingly supplemented it with the results of his own experimental work. The ensuing discussion, over which L. D. Huntoon presided, was opened by C. F. Chandler, emeritus professor of chemistry in Columbia University, who related some amusing incidents in his early experiences with zinc. W. McA. Johnson followed with a short account of the results of his experimental work in developing a continuous zinc furnace, in which a slag, with an extremely low metal content, is obtained, copper or lead is obtained in the form of matte or bullion, and the zinc is condensed, about 75% of it yielding spelter and only 1 to 5% blue powder. The furnace yields 15 to 20% blue-dust. On the basis of present experiments, it is estimated that the cost of electrodes will be 25 to 50c. per ton, and that, using a 250-kw. furnace, the thermal efficiency will reach 65% and the power consumption will be 750 to 800 kw-hr. per ton of material smelted. Dr. Cowles related the results of some early experiments made by himself upon the electrolysis of zinc, and E. G. Spilsbury described some early experiences in zinc metallurgy. J. W. Richards made an interesting comparison of the various types of electric furnaces, and the discussion was closed in a witty speech by J. F. Kemp, who proposed a vote of thanks to those who had spoken. The meeting was followed by a smoker in the Institute rooms.

The meeting of the New York Section of the Mining and Metallurgical Society, November 18, was devoted to the discussion of flotation and alternative schemes for improving the saving of slime in copper and zinc mills. J. Parke Channing introduced the discussion with a summary of present conditions. He brought out the fact that in one case where a 35% copper concentrate was made by wet milling and flotation, the original concentrate would con-

tain about 20% silica, for example, and the flotation concentrate 30%. This was found to be due to the presence of magnetite in the ore which did not go into the flotation concentrate; and that this introduces a smelting problem. He furthermore said that it had been found that if ore was treated by leaching to recover the oxidized metals, it was not possible to follow this by flotation to recover the sulphides, but that the reverse process is applicable. He announced that at the Miami a new Deister classifier is to be placed in the mill. It consists of a vertical tube of about 10 in. diameter, a couple of feet high, and slightly larger at the top than at the bottom. Inside this are ten or a dozen cones, supported by the point downward. These have six slots, about $\frac{1}{2}$ to $\frac{3}{4}$ in. wide, extending from near the edge to the point where they come together and make an opening. They are placed so that the slots in one are at 45° to those above and below. This classifier has been found to give greatly improved results. Experiments with Butchardt riffles on a Deister table were also cited as showing that 40 tons per day could be treated on one roughing table. Otto Sussmann gave most interesting details as to difficulties in smelting the Butte & Superior flotation concentrate. The drying of the concentrate is one of the big problems, and the water now accounts for \$1 per ton of the freight rate. The moisture furthermore makes trouble in roasting the very fine concentrate because it bolls. The greatest difficulty, however, is that the oil in roasting dissociates, the hydrogen burning off and leaving finely divided carbon on the particles of ore. At a later stage this reacts with the partly roasted material, producing metallic zinc which distills off. The oil also causes the concentrate to 'ball up' in the roasters, and there are incidental difficulties in charging the retorts to capacity.

It was announced that at the meeting of the Council the same day, the gold medal of the Society had been voted to Mr. and Mrs. H. C. Hoover for their distinguished contributions to the literature of mining.

BOSTON

AMALGAMATED COPPER.—RAY CONSOLIDATED RESULTS.—NEVADA CONSOLIDATED AND DAVIS-DAILY.

The taking of testimony here in the case of some stockholders in the Alice company who are suing the Anaconda Copper Mining Co. to set aside its acquisition of the Alice mine, brought out the fact that two men claim credit for the origin of the Amalgamated Copper Co. These are Thomas W. Lawson and his former partner in mining ventures, A. C. Burrage. The suit, which is in progress at Butte, called for the testimony of Lawson and Burrage as principals in the formation of the Amalgamated company. The former claimed that he first brought the matter to the attention of Henry H. Rogers, while Burrage said that his recollection differed from that of Lawson. He said that he went to Butte and inspected the ground and recommended that Rogers and the Standard Oil Co. should buy the whole hill. Lawson, he said, was interested in selling Butte & Boston to the Company, but beyond that he did not recall any specific matters in which Lawson figured in forming the Amalgamated. Burrage said he did not think much of Butte & Boston at the time, but recommended its purchase, together with the hill as a whole. Lawson testified that, although Amalgamated was not formed until 1899, it was talked about as early as 1896. He said the formation of Amalgamated and the taking over the control of the United Metals Selling Co. was for the purpose of getting control of the production and marketing of copper, the main idea being greater stability in production and price.

The quarterly report of the Ray Consolidated Copper Co. is somewhat disappointing in Boston. Some people are asking if it will not be necessary for the Company to borrow money upon its unsold copper in order to pay the next dividend. The main troubles of the Company are attributed to the drought in that district, which always comes along in the fall of the year. A Boston visitor to the district said when he was there in the spring the river was a torrent, but when he returned in the fall it had

almost disappeared and only a dry creek bed remained.

Charles Hayden, of Hayden, Stone & Co., has returned to Boston after a trip of seven weeks, inspecting the properties in which his firm is interested in Butte, Ely, Bingham, Ray, Chino, and Juneau. He stated that Nevada Consolidated has only 12 or 13 years to live at the current rate of production.

The hearings before the magistrate here in the suit of Louis Ross, mining engineer, against A. C. Burrage, claiming \$2,500,000 of the stock of the Chile Copper Co., is still going on and will probably continue the balance of November.

Former Senator William A. Clark has many admirers in Boston who are interested in the honors paid him by way of celebrating his fiftieth anniversary as a citizen of Montana. He was one of the first pioneers into the Bannack and Alder Gulch districts in Montana, and the first year he was there cleaned up about \$2000 in gold-placer workings. He afterward dealt in merchandise extensively, later moving to Butte, which he has ever since called his residence, notwithstanding that he owns palatial New York and Paris homes.

Davis-Daly, on the Boston Curb, has recently been easier in price, selling under \$2 per share. It is announced that full operations have been resumed at the mine. The Creden management has practically reversed the underground procedure of its predecessors. Davis-Daly now has a comfortable treasury, and instead of Boston sending money to Butte, Butte is sending it to Boston.

MIAMI, ARIZONA

TEST MILL AT THE INSPIRATION CONSOLIDATED.—THE ARIZONA COMMERCIAL.—CHANGES AT THE BOSTON & SUPERIOR.

The Inspiration Consolidated probably will begin operating its new test-mill December 1. However, this will depend upon electric power and water. An 8-in. pipe-line has been laid from Wog's ranch to the mill, but no water as yet has been sent through the line. The power is dependent upon the Roosevelt-Miami-Superior transmission line, now in course of construction, and it is not certain that the wires will be at the Inspiration plant by December 1. The mill will have a daily capacity of 600 tons and will be equipped with two 20-in. conveyor belts, one automatic weighing machine, two 48-in. fine reduction disc crushers, one 36-in. disc crusher, one 48-in. roller mill, four Hardinge mills, four drag classifiers, three No. 6 Wilfley tables, two Deister multiple decks, one No. 4 Deister table, two No. 2 Deister tables, two double-deck slimers and one improved slimer, two elevators, and the flotation machinery. The mill will be so constructed that the method of treatment may be changed as often as desired with but little trouble. The excavation work is progressing rapidly for the air-compressors and transformer building, and within a few days concrete pouring will be in progress. The crushing plant at the Scorpion shaft has been completed and is ready for operation. The American Bridge Co. has four gangs busy riveting the ore-bins, and one span of the conveyor housing between the bins and the coarse-crushing plant is now in place. The MacArthur Brothers company is making rapid progress at the preliminary grading for the smelter, and the railroad will be laid to the site in a short time. Since the arrival of the Inspiration's new locomotive the Southern Pacific engine has been returned to that company, and the Porter locomotive is handling the work.

At the Arizona Commercial property, a concrete dam has been built in the drift on the 1200-ft. level at a point between the shaft and the cross-cuts that were recently driven into the vein. The water, which seems to come altogether from the vein, is diminishing in volume, and at the present has a pressure of less than 10 lb. It is probable that the flow will disappear as the vein is drained.

The Iron Cap has about 40 ft. to cut before the connection with the Eureka shaft of the Arizona Commercial is established. The raise from the 800-ft. level will connect with the 600-ft. level about the same time that the drift does. The Iron Cap is maintaining its record output of the immediate past few weeks, and the management

expects it to increase the output for the month of November.

JOPLIN, MISSOURI

DEEPEST MINING IS IN THE MIAMI, OKLAHOMA, DISTRICT.—IMPORTANT LEAD DEVELOPMENT AT DUENWEG, MISSOURI.—ZINC ORE PRICES WEAKEN.—SHEET-GROUND DEVELOPMENT.

The deepest mining in the Missouri-Kansas-Oklahoma zinc and lead district has been started by the T. F. Lennan Mining Co., in the North Miami, Oklahoma, field, where a pump with a capacity of 2000 gal. of water per minute has been installed at a depth of 310 ft. and will drain the ground to a depth of 320 ft. A continuous orebody, from a depth of 260 ft. down to 320 ft., will be mined. Heretofore the Company has been doing all of its work at the 260-ft. level. Both zinc and lead ores are produced. They are low grade, selling for several dollars per ton beneath the prevailing basis price; yet the richness of the ground counterbalances the low grade of the concentrate. The Company operates a concentrating plant of 500 tons capacity per shift, and for over a year has been one of the heavy producers of the Miami camp.

At Duenweg, Missouri, important development is resulting in an unusually heavy production of high-grade galena. The work is being done by the Little Bob Mining Co., and it is interesting to note, in connection with this development, that the Company was reported to be about exhausted from a producing standpoint just about a year ago. At that time the Company had been a heavy producer of lead ores for more than a year, but the ground at the immediate place of operations was exhausted, and presumably the Company had dropped out of the producing class. Drill prospecting disclosed lead ore in rich formation, about 800 ft. north of the mill. A shaft was sunk and this new ground is now being opened. Several drifts are in the ore, which is in soft ground requiring timbering, and the ore is trammed to the mill where the recovery has averaged 10.5% for the past month. The Company is now producing an average of 125,000 lb. of galena concentrate per week, although the output has run as high as 150,000 lb., and the grade of the product is nearly 84% metal, meaning a settlement of \$4 in excess of the prevailing basis figure for grades carrying 80% metal, the standard of the district.

Prices for zinc ore are ranging from \$36 to \$43 per ton, basis of 60% metallic zinc, the lowest offerings of recent years. The greatest slump came at the close of November, when companies that had been paying \$40 to \$42, basis, offered no more than \$36. Many companies cannot operate at these prices. For the corresponding period of 1912, zinc ore brought \$54 to \$58, basis, with choicer grades selling up to \$61. Spelter, which is now weak at \$5.15, was then firm at \$7.35 per 100 lb. The district production of zinc sulphide is running close to 4800 tons per week, with shipments of about 4500 tons, meaning a gradually accumulating surplus. The Joplin field produces the heaviest tonnage of zinc ore, although Webb City occupied the leading position for many years.

Steady production is reported by the Portland Mining Co., occupying a lease of the L. P. Cunningham estate, northeast of the American Zinc, Lead & Smelting Co.'s large mines at Prosperity, Missouri. In virgin territory, the progress of this mine has been watched with much interest. The mill has a capacity of 500 tons per shift and is making a high-grade zinc sulphide, which, however, contains barely enough iron to result in penalizing. Work is conducted in a thin sheet formation found at a depth of 190 to 210 ft. Formerly the mill was operated at the Stotts City, Missouri camp, but was recently moved to its present situation.

The Underwriters Land Co., operating on the Connor estate adjoining the city limits at the west of Joplin, has sunk a new shaft to a depth of 120 ft., where sheet ore is found and where a concentrating plant will be erected. The Company is already operating the Priscilla and the Falls City mills, both of which are among the largest plants in the west Joplin field. The ore in this district carries about 3% zinc sulphide and a small per-

centage of galena. The Company has recently acquired leases in the North Miami, Oklahoma, field and will begin drilling operations in that district.

The Picher Lead Co. has begun drill prospecting in the Tar Creek region, three miles northeast of Miami. In this new field, the pioneer plant, operated by Barnes & McConnell, is now running steadily. The ores of this region occur at depths of from 250 to 300 feet.

MELBOURNE, AUSTRALIA

SYDNEY STOCK EXCHANGE.—MINERS' CARELESSNESS.—CAPITAL FOR FOREIGN VENTURES.—CARPATHIA MINE.—VICTORIAN STATE COAL MINES.

The Sydney Stock Exchange has taken steps to put an end to cornering of stocks. Following the procedure of the London Exchange, it has enacted that "the committee may suspend, either indefinitely or for such time as they think fit, the buying in of any debentures, transfers, scrip, or other securities, when circumstances appear to make such suspension desirable. The committee may from time to time, either during its continuance or after the termination of any such suspension, remove, renew, or reimpose such suspension." The rule has been generally welcomed except by those whose operations have been unpleasantly restricted by it, and the only criticism of it has been voiced by a writer who considers that the action of the Exchange, "while doing good in the direction of checking manipulation of corners, may depreciate the value of many investments by freeing the hands of the bear." This seems a reasonable objection to take to the Exchange's legislation.

Though less than a year has elapsed since the lives of over forty men were lost as the result of a fire in the underground workings of the Mt. Lyell company's North Lyell mine, a strike is reported as having taken place at that very mine, owing to the action of the Company in dismissing a man for exposing the mine and the danger of a new disaster. The management, not anxious to have a recurrence of a disaster of such magnitude, gave instructions that no fires were to be lighted at the shaft head-frame, for fear of ignition of dry woodwork. Despite these instructions, one of the shaft-tenders insisted on lighting fires there, and as he persisted in doing so after he had been remonstrated with and warned, he was dismissed. The result was that the men left work. Fortunately, however, the union officials disapproved of the men's action, and after the loss of two shifts work was resumed. But what hope is there of such men listening to reason? To down tools because the Company dismisses a man who is putting their lives in peril by his disobedience to orders argues them fools of the very first quality. [It may be explained that, at Australian mines, the head-frames are all in the open, and in winter the shaft-tender, although having a small house for shelter, gets cold, and it is customary to light small fires in cans or other apparatus for warmth.—EDITOR.]

Attention has been directed to the large amount of Australian capital that has of late years gone abroad for mining investment or speculation. Siam, the Federated Malay States, Java, and the Philippines have all benefited largely; and now there is a proposal to finance the working of an oil property in the island of Timor. It seems not unlikely that labor legislation is responsible in at least some degree. At present so much of the income of mining companies at work in Australia is eaten up in wages that profits are much smaller than they should be. In the islands of the archipelago, north of Australia, even lower-grade concerns may yield a much larger percentage of profit; and though there is always an amount of anxiety in connection with the working of a company whose scene of operation is thousands of miles away, this is nothing compared with the worry caused by constant labor troubles and the annoyance of feeling that the content of one's property is not in one's own hands.

The report of R. Logan Jack on the Carpathia, the leading mine of the new Ardlethan field in New South Wales, has resulted in a collapse of the shares. This is rather on what was *not* said in the report than on what *was* said. The public, reading between the lines, realized that the

mine had not yet developed any definite lode, and so hastened to get out. Mr. Jack gave no estimate upon reserves, because, no ore having been exposed on three sides, no estimate worth the name was possible.

According to the financial statement covering the operations of the Victoria State Coal Mine, placed before Parliament by the treasurer of the state, a net profit of \$201,000 was made for the year ended June 30. This compares with a declared profit of \$48,000 in 1911-12, and \$117,000 in 1910-11. In no case was the expenditure on any such items as shaft-sinking and development charged against revenue, nor was any provision made for depreciation before arriving at the net surplus profit. Receipts, including \$12,000 on sundry account, came to \$1,033,000, while working expenses included \$791,000 for the raising and shipping of coal, and \$30,000 for interest. Receipts were \$68,000 in excess of the previous year and working expenses \$94,000 less than those of 1911-12. As the output of coal declined from 470,261 tons to 457,653 tons, higher prices must be credited to sales, and it would be interesting to know what the Government Railway Department paid for the 266,880 tons it used. During the year the state treasurer made an appropriation for the mine of \$261,000. Increases in expenditure in capital amounted to \$177,000, making the total at which works, machinery, and plant stand, at cost, at \$989,000. The total net profit to date, \$367,000, has been appropriated to the sinking and depreciation funds. During the year, \$136,000 was expended on head-frames, machinery, rails, ropes, plant, etc., bringing the total expenditure on these items up to \$445,000; but whether the extra expenditure has been accompanied by a commensurate increase in the mine's capacity is to be doubted. There is a very marked tendency on the part of the Victorian government to show that the mine is a successful venture, and its figures are regarded with some suspicion.

REPUBLIC, WASHINGTON

WORK AT THE BEN HUR, SAN POIL, SURPRISE, AND QUILP MINES.—NEW DEVELOPMENT AT SHERIDAN.—DRILLING IN THE WOLF DISTRICT.

The Ben Hur Leasing Co. is to increase ore shipments from the Ben Hur mine to the smelters to 100 tons per day. The San Poil Consolidated Co. shipped, early this week, bullion valued at about \$5000, which is the approximate value of the weekly shipments from the San Poil mill. In the Surprise mine the leasing companies are operating with fair profits. The McFarland Leasing Co. has two men employed and made its initial shipment. The Sharp Leasing Co., E. J. Delbridge, manager, has increased its machine drills by adding a heavy piston sinking drill for underhand stoping a large shoot of ore on the 500-ft. level, north of the incline shaft. This ore lies north of a fault, but driving and cross-cutting on the 600-ft. level has failed to disclose it. This Company will sink on it from the 500 to the 600-ft. level. At 500 ft. it is 7 to 12 ft. wide, averaging about \$14 per ton. Nine carloads of ore was shipped on November 18 from the mine, part of which was broken by the lessees and part by J. L. Harper, who holds the mine under bond. The 700-ft. level is under development by Mr. Harper. A drift south of the incline shaft has opened the No. 2 ore-shoot, which extends from the 600-ft. level 300 ft. south of the main incline shaft.

A new feature in the Quilp mine is the production of a specimen of ruby silver. The Anaconda Mining & Reduction Co. contemplating the erection of a cyanide plant for treatment of ore from the Republic mine.

Ore said to be worth \$182 per ton in gold, silver, and copper has been opened in the Sheridan camp, although reports are conflicting at present. Several prospectors have gone from Republic and staked claims. The camp is old and may come to the front in time. It lies partly in Okanogan and partly in Ferry county, about ten miles westward from Republic.

The Boyle Brothers Diamond Drill Contracting Co., operating a drill at Wolf camp, 7 miles northeast of Republic, has suspended work for the season, owing to frost interfering, but will resume in the spring.

General Mining News

ALASKA

JUNEAU

On November 29 the following dividends were paid by the companies operating on Douglas island:

Company.	Dividend No.	Per share.
Alaska Mexicar.	72	\$0.20
Alaska Treadwell	103	1.00
Alaska United	25	0.50

ARIZONA

COCHISE COUNTY

It is probable that the Shattuck company will erect a blast-furnace to treat its lead ores, and so save the freight to El Paso.

According to Walter Douglas of the Copper Queen company, plans have been completed for a pension system among the employees of this Company. The benefits of the system will be enjoyed by employees who have been 15 years or longer in the service of the Company. Pensions will be provided not only for those who shall have attained the retirement age of 70 years, but also to those who, in the opinion of the Company, have become physically or mentally disqualified and for that reason are retired by the Company. At the present time there are 113 employees who have been on the payrolls of the Company for 15 years or more and who therefore can qualify for pensions. The amount of the annual pension will be 2% of the employee's annual salary for the three years of active service immediately preceding his retirement, multiplied by the number of years' service, with a maximum of 60% of such annual wages. Pensions will be granted up to \$1000 as a maximum.

GILA COUNTY

It has been practically determined to alter the first five sections of the Miami concentrator, to conform with the sixth unit which now secures a two pound per ton better extraction than the rest of the plant. The treatment of mixed sulphide and oxide ores has been puzzling, and a 20-ton experimental plant will soon be started by the Miami company upon a new process, details of which are as follows: (1) Coarse crushing and removal of fine dust; (2) rough water concentration to take out coarse sulphide matter; (3) roasting of tailing from above; (4) leaching with sulphuric acid solution; and (5) precipitation of copper by electrolysis and regeneration of solution with sulphurous acid gas, solution then being used again for leaching.

GRAHAM COUNTY

During October the Arizona Copper Co. produced 1775 tons of copper. Considerable progress was made during the month in getting the new furnaces into operation.

CALIFORNIA

BUTTE COUNTY

(Special Correspondence.)—The Ophir Gold Dredging Co. has about 10 acres of ground to treat before its second boat goes out of commission. This dredge has 5-cu. ft. buckets, 22 being dumped per minute, and the motors have a total of 280 hp. The Company owns its water-supply, which is procured from two wells drilled 118 ft. each, and one 116 ft., yielding 40 miner's inches of water per day. This is pumped to the dredge pond from the wells by a 4-in. centrifugal pump, driven by a 20-hp. motor. El Oro No. 2 dredge, with 5-cu. ft. buckets, is at present working in some tight ground. The bucket-line contains 93 buckets weighing 1400 lb. each. Instead of the usual revolving trommel, this boat is fitted with two shaking-screens, which do equally as good work as the revolving apparatus. Power consumed is from 240 to 300 amp. for the whole boat. The Oro Water, Light & Power Co. has four dredges in operation. One boat was changed from 5 to 6-cu. ft. buckets, using the same hull, and the gold-saving tables were increased. This change resulted in an increase of 20% in

gravel handled. Over a period of five months the boat averaged 235 cu. yd. per hour. The other three 5-cu. ft. boats are cutting into a bank from 38 to 42 ft. high, of which 22 ft. is a clay overburden. They only average about 100

NATOMAS CONSOLIDATED ROCK-CRUSHING PLANT AT OROVILLE USING DREDGE TAILING.

cu. yd. of gravel per hour. Power is obtainable for all dredges in the field at 1c. per kilowatt hour.

Oroville, November 18.

In the Emma mine, worked some time ago by the Nimshew Gold Mining Co., a piece of quartz and gold, valued at \$726, was extracted by O. H. Rugb during the past week.

IMPERIAL COUNTY

(Special Correspondence.)—The new mill of the Imperial Reduction Co. is nearing completion, and should be in operation by the beginning of next year. This Company has a capital of \$250,000, with its head offices at Pasadena.

Ogilby, November 22.

INYO COUNTY

Salt Lake City people are interested in the Cerro Gordo mine at Keeler, and results are satisfactory. An ore-shoot $4\frac{1}{2}$ ft. wide, containing 70 oz. silver, 4% copper, and 10% lead has been opened on the 700-ft. level, and 15 tons daily is shipped from it. Thirty men are employed. From an old slag dump on the property, 10 tons, yielding \$16 per ton net, is also being shipped. Also 10 tons of high-grade zinc carbonate ore is mined daily. Lead ore is being sent out from the Christmas mine at Darwin, while the Custer, Lucky Jim, and Domingo mines are actively worked.

KERN COUNTY

(Special Correspondence.)—Every mine in the Amelia mining district has taken a new start, new operators have taken hold and are opening the various mines, milling, and shipping ore. Not for twenty years has there been such activity in this district, and all are satisfied. The Barbara Rosa, owned by Mr. Parlow, has been sold to Mr. Carr of San Francisco, and he is treating ore at the Amelia mill, which he has leased. The Cow Boy has changed hands and the owners are shipping ore. The Gold Peak property has been acquired by new people and they are opening good ore. Mr. Wilson, who took over the McKnight property, has installed new machinery and is to begin crushing a large tonnage of ore. The Zenda Mining Co. has been negotiating to sell its property and has begun work. J. B. Ferris has been running his arrastre on molybdenite and gold ore during the past year, and proving a large body of ore. He has water-power for the plant and power costs are low. A United States Government Geologist was recently sent to examine Mr. Ferris' molybdenite ore, and seemed much surprised that such a large tonnage has been opened, and took a number of samples for testing purposes.

Caliente, November 15.

LOS ANGELES COUNTY

A group of Sawtelle men are engaged in prospecting along Mariposa creek where a body of deep unworked gravel is said to be present.

PLACER COUNTY

(Special Correspondence.)—The dredge on the American river, 7 miles from town, is working well on the river bars, and an ultimate capacity of 130,000 cu. yd. of gravel per month is anticipated. This boat has $7\frac{1}{2}$ -cu. yd. capac-

ity buckets, taken from Pacific No. 1 dredge at Oroville, while a new hull to withstand river floods was constructed.

Auburn, November 20.

SHASTA COUNTY

A suit will be brought by the Shasta County Farmers' Protective Association against the Mammoth Copper Co., at Kennett, on account of alleged damage to crops by smelter fume. This Company has bought the Spread Eagle group of 21 copper claims, lying four miles northwest of Copley.

At the Baker mine the shaft is down 85 ft., and is to be continued to 200 ft. depth, where cross-cutting will be done.

SIERRA COUNTY

(Special Correspondence.)—A two-compartment shaft is down 60 ft. at the Lee mine, near Sierra City. Good ore over a great width has been opened, and a 10-stamp mill is to be erected for prospecting work. Electric power will be used. Forty men are employed, and the property is controlled by R. G. Gillespie of Pittsburgh, Pennsylvania, C. D. McGonigal being superintendent. Both the Keystone and Chips mines are closed for the winter.

Sierra City, November 22.

At a distance of 2000 ft. from the portal of the main adit of the Tighner mine, at Alleghany, and 1100 ft. below the surface of the mountain, a 500-ft. shaft is being sunk on the lode. An electric hoist and pumps are to be installed.

SISKIYOU COUNTY

Gravel property on Greenhorn creek has been bonded by the Butte Dredging Co., which has had seven men prospecting, by shaft sinking, since last April. A dredge is to be moved from Oroville next spring to treat this gravel.

TRINITY COUNTY

The 20-stamp mill for the Globe Consolidated Mining Co., near Dedrick, is nearly complete. It includes an all-sliming cyanide plant. An aerial tramway 6000 ft. long has been constructed, also 6800 ft. of flume and 3700 ft. of 20-in. steel pipe for water power. The mines have plenty of ore opened. About 100 men are employed at present.

YUBA COUNTY

The Wonder mine in the Brownsville district is being developed by H. W. A. Docker. The vein is about ten feet wide, and an ore-shoot 400 ft. long at the surface has been followed to a depth of 45 ft. on this vein.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A mineral discovery of great richness has been made at the Lucas property on Democrat mountain, that surpasses anything of recent years in that section. The orebody is 2 ft. wide and at a depth of 12 ft. from the surface assays 1000 oz. of silver per ton. The vein is the east extension of the Polar Star, one of the early-day heavy producers. L. Lucas is owner. B. O. Bonham, leasing on the Paymaster mine in East Argentine district, has uncovered an 8-in. streak of smelting ore that assays 85 oz. silver, 1.75 oz. gold, and 19% copper. Operations are being prosecuted on the 600-ft. level, and machine-drills are being installed. Shipments will be started this month. Hanson & Co., leasing on the Independence vein at the Wilcox property, are sending out carload lots of ore that bring a mill settlement of 80 oz. silver, 2.30 oz. gold, and 18% copper. The product is being consigned to the smelter at Salida. A Temple electric drill has been purchased by the Rosebud M. & M. Co., controlling a big group of claims on Democrat mountain. Cross-cutting has been started 800 ft. from the portal of the upper adit, and the north extension of the Astor vein will be reached within the next 20 ft. G. W. Teagarden is manager. The Golden Glory adit on Saxon mountain has opened a vein 1580 ft. from the portal. The ore is 7 ft. wide and from numerous assays the average value of the ore is given at \$18 per ton in gold and silver. Driving east and west has been started. J. F. Puchert, of Idaho Springs, is manager. Rendahl & Co., leasing on the 500-ft. level of the Anamosa mine, made a shipment of five tons of first-class ore last week, and returns of 187 oz.

silver per ton were received. These lessees are stopping on a body of ore that is 14 in. wide.

Georgetown, November 18.

EAGLE COUNTY

Frank C. Goudy, F. B. Goudy, and L. L. Twitchell, on November 19 at Denver, filed with the Secretary of State articles of incorporation for the Horse Mountain Mining Co., capitalized at \$50,000. The purpose of the Company is to purchase and develop certain mining claims in Eagle county.

GILPIN COUNTY

The French Flag mine, situated on the boundary line of Gilpin and Clear Creek counties, at the head of Gilson gulch, is proving to be one of the best properties of that district at the present time, and the operators, consisting of a pool of local men and Eastern capitalists, will make good profits out of it. About \$90,000 of ore has been opened between the 135 and 235-ft. levels, while other levels are showing well. Shipments are made to Idaho Springs sampling works. In the lower Russell district the Two-Forty mine is opening well; Walter Flagler is manager. Rich gold, silver, and copper ore continues to come from the Pittsburg mine. At Black Hawk, 15 stamps of the Polar Star mill are being overhauled after being out of commission for some time.

GUNNISON COUNTY

The Revenue mine and mill, on Quartz creek, has been acquired by George T. Edwards, of Salt Lake City, Utah. A cyanide plant will be added and other changes made in the mill. The Elk Mountain Mines & Tunnel Co. is driving an adit to cut the veins in the old Copper Queen property, about ten miles from Crested Butte, and expects to reach them in about 400 feet.

LAKE COUNTY (LEADVILLE)

During the winter, the Mt. Champion, Miller Gold, and Lackawanna Bell mining companies will continue development in Lackawanna gulch. The zinc carbonate opened in the New Discovery, on Fryer hill, did not continue as rich as expected, and has been temporarily abandoned, pending work in other parts of the mine. Lessees and others at the Dinero, Seneca, Dunkin, Lovejoy adit, Little Ella, Castle View, and other mines are busy.

LAS ANIMAS COUNTY

Since the inception of the coal miners' strike there have been 18 lives lost. The operators refuse to meet representatives of the union who have been mixed up in the recent strike affrays. William B. Wilson, Secretary of Labor in the United States Government, is at Denver investigating the whole trouble.

SUMMIT COUNTY

Dredging in the Breckenridge district continues to produce large quantities of placer gold. The Bucyrus boat of the Colorado Gold Dredging Co., operated in Swan valley, near Swan City, recently shipped gold valued at over \$11,000. This was the result of the last ten days of dredging in October. The boat is working its way through unusually rich gravel this year and will average an output of over \$1100 in each 24 hours of actual operating time. The Reliance Gold Dredging Co.'s boat is working close to the junction of French creek with the Blue river, and is in rich gravel. The Reiling boat of the French Gulch Dredging Co. is being drawn along over the surface of French gulch with wire cables toward its new pit, which is about a mile upstream from the old one, from which the boat is said to have taken out rich gravel.

TELLER COUNTY (CRIPPLE CREEK)

The 400-ft. level of the Eclipse shaft, on the southwest slope of Battle mountain, submerged and inaccessible for the past ten years, has been recovered by the pumps of the El Oro Mining & Milling Co., operating the mine, and of more importance to the stockholders of that Company, R. G. Mullen, who entered and made a casual examination, reports ore exposed awaiting development. An 11-drill compressor has been installed. The danger of a coal shortage at the mines is being reduced by the daily arrivals of this fuel. The Christmas Gold Mining Co. has

been awarded a judgment of \$4074 against John T. Milliken, of the Golden Cycle Mining Co., on account of profits made out of a lease of the Christmas mine under a certain agreement. The Vindicator company controls this property now and is using the Golden Cycle company for alleged illegal extraction of ore. The El Paso Extension Gold Mines Corporation has been incorporated with a capital of 200,000 shares of \$5 each. The properties to be developed lie south of the El Paso Consolidated's mine on Beacon hill.

The Neville mill, constructed by the Free Coinage Gold Mining Co., on its Bull hill estate, on which is situated the town of Altman, at an altitude of 10,728 ft., was started on November 20. The plant is of 100-ton capacity, includes a crusher, Hardinge mill, three Deister tables, slime plant, and Oliver filter. The mine has been well developed for continuous operation.

A new tube-mill and more powerful electric motor are to be added to the plant at the Colburn mill owned and operated by the Ajax Gold Mining Co. The November production will be about 7100 tons of ore. The mine is shipping ore to both custom and its own mill for treatment. The Kavanaugh mill is treating 75 tons per day of low-grade ore from the Joe Dandy dump. Water in the Gold Coin shaft of the Granite company is now 38 ft. below the 1100-ft. level, where promising development is under way. Fifteen feet of ore is being mined in No. 2 vein of the Pharmacist mine, on Bull hill, by the lessee, B. F. Hill. Without sorting, this ore averages about \$13 per ton.

GEORGIA

The Jumbo gold mine at Dahlonega is showing well as a result of the development work of the year. A 10-stamp mill is busy crushing free-milling ore. The mine is managed by M. F. Burke, who recently returned to Boston, Massachusetts.

IDAHO

BONNER COUNTY

(Special Correspondence.)—Approximately \$50,000 has been expended in the last year developing the old Webber mine, $5\frac{1}{2}$ miles from Pend Oreille lake, 50 miles east of Spokane, now owned by the Pend Oreille Mining & Reduction Co., a corporation consisting principally of stockholders in Chicago, Illinois, and results are so promising that plans are being prepared for a concentrator, to be erected next summer, according to S. P. Donnelly, of Lakeview, one of the heaviest individual owners of the property. The formation now exposed in the lower workings of the mine is said to be similar to that in the large silver-lead producers in the Coeur d'Alene region. Work will be continued during the winter.

Spokane, November 22.

LEMHI COUNTY

From the shipment of 11 cars of ore from the Gilmore mine, in October, the net profit was \$4400. Development work on the 350-ft. level continues to open ore of a better grade than that found between the 200 and 300-ft. levels, some of which assayed up to \$40 per ton. During November an adit was started at the west end of the property and will be 1000 ft. long. No. 4 raise in the Martha vein is up 105 ft. in 7 ft. of gold-bearing ore containing a high percentage of iron. The new tramway, built jointly by the Gilmore and Pittsburg-Idaho companies, was recently completed, and has been running smoothly since put into practical use about two weeks ago. The tramway is now handling ores from both properties.

SHOSHONE COUNTY

Rescue car No. 5, of the U. S. Bureau of Mines, which has been about two months in the Coeur d'Alene district, has gone to Butte, Montana. Over 200 men have been instructed in first aid, and several in the use of oxygen helmets. J. M. Anderson, who is in charge of the car, expressed himself as well pleased with his trip to the Coeur d'Alenes and with the interest displayed by owners and miners. He states that the big mines have installed apparatus for successfully coping with accidents.

The 300-ton mill which the Federal Mining Co. is building at the Frisco mine, at Gem, has the framing up, and

32 men are rushing the building to receive equipment before the winter sets in. Eighty men are employed at the mine.

The Hecla Mining Co., operating at Burke, paid its regular monthly dividend of \$20,000 on November 20.

MICHIGAN

HOUGHTON COUNTY

The managements of Ahmeek, Allouez, North Kearsarge, Wolverine, and Mohawk companies announce that unless there is soon a substantial increase in men returning to work, they will close down for the winter.

MINNESOTA

ST. LOUIS COUNTY

(Special Correspondence.)—The season for shipping ore has closed, and it is estimated that movements total approximately 45,000,000 tons. The finish was marked by one of the worst disasters in the history of the Great Lakes, when a storm caused the loss of over twenty steamers and about 250 lives. The property loss is estimated at \$5,000,000. It is reported that the Mesaba electric railway, operating between Hibbing and Gilbert, will be extended next season from the latter place to Aurora on the east, and probably westward from Hibbing to Grand Rapids. The Pickando-Mather company has given up its lease on the Yankey mine at Virginia, and has taken the lease formerly held by the New York Steel Co. on the Kellogg mine at Biwabik, the latter Company having become bankrupt. The Cuyuna iron range is attracting a great deal of attention just now. Last week, a party including officials of the United States Steel Corporation, Oliver Iron Co., D. M. & N., and D. & I. R. railways, visited various mines of the district. A considerable number of drills are at work, and the ore-bearing area is being proved of greater extent. Some properties are being stripped by steam-shovels, and at the Rowe the overburden is being moved by hydraulicking. The Cuyuna range lies about 160 miles west of Duluth.

Duluth, November 16.

According to the estimates of the underwriters carrying the risks of the steamers and cargoes lost in the recent storms, the total loss to cargoes and vessels was about \$8,500,000. Of the total, \$2,000,000 was lost on cargoes and \$3,500,000 on the vessels, which amounts to the insurance. The Great Lakes Protective Association carried about 25% of the total risk, the remainder being carried by American and British marine insurance companies.

NEVADA

ESMERALDA COUNTY

An interesting decision has been handed down by Judge Somers, of the District Court, regarding the suit of the Goldfield Consolidated Milling & Transportation Co. v. the old Sandstorm Annex Gold Mining Co., W. H. Brock, E. S. Johnson, and A. Huyser, in which the plaintiff asks for a restraining order against the defendants who are removing tailing which has flowed from the Consolidated mill on to the defendants' ground, while the latter ask to have the temporary restraining order, issued earlier, dissolved. The whole question concerns the value of the tailing, and by concentration of metal content on the surface of dumps by natural processes, a rich product, up to \$135 per ton, was being scraped off by the defendants. They stated that their object was to sample the dumps. The court decided that the defendants should be restrained from removing the tailing, except such as required for actual sampling for a condemnation suit now pending.

HUMBOLDT COUNTY

The deal to consolidate the Nenzel Crown Point Mining Co., the Rochester Mining Co., and the Rochester-Weaver Mines Co. is practically completed. It is proposed that a new company, the Rochester Consolidated Mines Co., take over the three properties and develop them. The capital of the new corporation is to be \$1,500,000, it is said. Mr. Nenzel, it is understood, owns the controlling interest in all three of the mines which are to be consolidated. He states that more than \$265,000 in ore al-

ready has been taken from the mines. It was affirmed that the papers would not be signed until the first of December, and that the consolidation would go into effect January 1, 1914. Salt Lake and Ogden capitalists who have been interested in the consolidation plans include Mr. Nenzel, J. F. Cowan, John Dern, M. S. Browning, and Le Roy Eccles.

LINCOLN COUNTY

The Yuha Leasing & Development Co., which is operating in the old Raymond & Ely property at Pioche, made a trial shipment of ore last week, consisting of 210 sacks, 42 of which contained gold ore from the bottom of the Greenback winze. Development work on the property is opening some good ore.

LYON COUNTY

The Mason Valley Mines Co. has taken over the Montanaverington property, and will be thoroughly developed. An assay office has been installed near the mine.

The Nevada Douglas Copper Co. reports as follows for October:

Ore shipped, tons	4,522
Average copper content, per cent.....	6.45
Copper content, pounds	583,331
Gross revenue for month.....	\$97,708

MINERAL COUNTY

The Aurora Consolidated company's new mill is almost under cover, and according to M. P. Kirk, of Kirk & Leavell, the plant should be finished by April of next year. There are 150 men employed at the mine and mill. The main adit is in 3200 feet.

NYE COUNTY

Eleven mines at Tonopah produced 51,221 tons of ore worth \$1,029,245 in October, some of the principal yields being as follows:

	Tons.	Yield.	Profit.
Belmont	15,233	\$310,788	\$187,333
Jim Butler	1,646	6,109
Tonopah	15,043	234,475	134,100
West End	4,455	40,108

WHITE PINE COUNTY

(Special Correspondence.)—A drill-hole put down recently by the Nevada Consolidated Copper Co. in the southwest part of Liberty pit, near the southwest corner of the

ELY, NEVADA.

Glroux company's Ora claim, passed through 240 ft. of overburden, then 560 ft. of ore. As there was no more casing on hand, drilling was stopped. It was supposed that there was no ore in this part, and close to the whole south end boundary of the Ora claim the Nevada Consolidated has proved ore for 500 ft. in depth. Drilling during the year is expected to show an increase of ore reserves of 10 to 20% over those of 1912. In some instances the position of the ore will necessitate the moving of dumps of overburden previously placed there.

Ely, November 19.

UTAH

JUAN COUNTY

The three-compartment shaft which is being sunk in the Eagle & Blue Bell property is progressing at the rate of

about four feet per day, according to Imer Pett, general manager. The shaft, when completed, will connect the 1350 and 1550-ft. levels, and will be completed before the first of the coming year.

TOOELE COUNTY

Since the announcement that a branch of the Western Pacific railway would be constructed from Wendover to the Deep Creek mining district, a distance of 40 miles, the field has become quite active. The Silver Bell mine will be developed during the winter, and the Dugway-Silver Bell has a dump of ore ready for shipment. In the Dugway district, the Dugway Bonanza Mining Co. is planning to resume work. The ore contains silver, lead, and gold.

CANADA

BRITISH COLUMBIA

On December 5 the Granby Mining, Smelting & Power Co. will pay a dividend of \$1.50 per share, equal to a total of \$225,000. This makes \$1,000,000 for the current year, and a grand total of \$4,767,043. During October the Grand Forks smelter produced 1,779,952 lb. of copper, 30,733 oz. silver, and 4108 oz. gold.

The Granby smelter treated 25,976 tons of ore during the second week of November, and shipped 436,000 lb. of blister copper.

No. 3 furnace at the British Columbia Copper Co.'s smelter at Greenwood is completed, but blowing in has been delayed through lack of coke and ore-cars. To October 1 the yield for the current year was 6,159,652 lb. copper, 89,088 oz. silver, and 18,021 oz. gold.

ONTARIO

During October the McKinley-Darragh-Savage mines produced 192,749 oz. silver from 5151 tons of ore. Vein No. 40 continues to yield rich ore, contributing 43,000 oz. to the total output. An application has been made by the Cobalt Lake Mining Co. to the mining commissioner, T. E. Godson, to fix an order for service parties to be served and time within which several defenses are to be filed for the draining of Cobalt lake. The application was filed in Toronto last week. This scheme will be far more extensive than the drainage of Kerr lake, as the town sewage and tailing from the Northern Customs, Cobalt Lake, McKinley-Darragh, and Nipissing mills flows into the lake at present. The application will probably be heard early in December.

At South Porcupine the Dome Lake mine has been sampled by two different companies during the past week. Veins on the 100 and 180-ft. levels were examined. The main shaft is down 220 ft., and is being sunk to 300 ft. It is stated that the North Thompson claim, at Porcupine, has been acquired by the Associated Gold Mines Co. of Western Australia.

YUKON

Gold production of the Canadian Klondyke company's claims during the weeks ended October 25 and November 1 was 2934 and 2879 oz., respectively.

KOREA

The October clean-up of the Oriental Consolidated produced \$144,000. Details of the September mill runs are as follows, there being 26,360 tons treated: Tabowie, \$26,443; Taracol, \$19,476; Kuk San Dong, \$3605; Maibong, \$15,001; Candlestick, \$5087; Candlestick cyanide, \$1859; Kuk San Dong cyanide, \$6442; Kuk San Dong dump plant, \$5583; Taracol tube-mill plant \$48,337; making a total of \$131,834. As there have been neither summer nor fall rains this year, the country is very dry, and already there is trouble in getting sufficient water for the mills. The Nuchadagle pumping plant is working in order to furnish water for the Taracol plants. The electric power-plant is furnishing power for lights only, owing to lack of water. It was intended to start retimbering the Tabowie shaft from No. 5 to No. 7 level this month, but as the mill will have to be stopped this winter for lack of water, unless there are heavy rains soon, it has been decided to keep the mill going on the better grade of ore from the lower levels while there is still water, and the shaft will be retimbered later on. The net profit for the month was \$33,110.

Personal

H. V. WINCHELL is in New York.

M. L. REQUA has gone to New York.

P. R. BRADLEY was at Yuma last week.

JOHN A. MCPHERSON is in San Francisco.

J. A. HOLMES was in New York last week.

ANTHONY F. LUCAS was in New York last week.

A. E. DRUCKER is no longer with the French Concessions in Korea, and is expected in London.

SIR ROBERT HADFIELD is on a brief visit to the United States.

R. H. ELLIOTT has returned from the lower San Joaquin valley.

S. H. BALL expects to return to New York early in December.

ALGERNON DEL MAR has gone to northern Ontario on business.

C. S. HERZIG was in New York from Butte and has gone to Cobalt.

WILLET G. MILLER has been visiting New York and has returned to Toronto.

T. J. GRIER is spending a holiday in the East and was in New York recently.

ALEXANDER ADIASSEWICH is visiting the dredging and oil fields of California.

ROBERT LINTON was in New York last week and has returned to Los Angeles.

CARL A. ALLEN has been examining mines near Ely, Nevada, for the past month.

C. W. MERRILL has returned to San Francisco after spending a holiday in the East.

W. H. STORMS has gone to Sutter Creek for the West Eureka Mining Company.

J. W. HUTCHINSON was badly injured in a collision near Palisade, on November 21.

H. FOSTER BAIN addressed the mining students at Stanford University last Tuesday.

ERNST LICHTENBERG has returned to London from professional work in Nova Scotia.

SUMNER S. SMITH has returned to Juneau from a trip through the interior of Alaska.

D. C. JACKLINE is reported to be seriously ill aboard his private yacht *Cypress*, off Seattle.

A. H. BURROUGHS is visiting California dredging fields on his way from Nome to New York.

FRANK A. BOWMAN has been appointed engineer for the Franklin and Kinney iron mines near Duluth, Minnesota.

CHARLES H. LEE has removed to 1103 Central building, Los Angeles, where he will continue his practice as a civil and hydraulic engineer.

W. O. PRAY, superintendent and manager of the Lockwood-Blazing Star mines at West Point, California, was in San Francisco last week.

R. B. LAMR, of Toronto, has gone north on a professional business trip through the Cobalt and Porcupine mining districts and will return about the end of this month.

CARLO SPRUYT has returned to Antwerp after an extended trip through the Western United States following the Alaskan excursion of the International Congress of Geology.

GEORGE BLANCHIN, of Paris, France, treasurer of the Central Eldorado Gold Mining Co., is in California on his annual inspection of the Company's properties in Eldorado county.

WILLIAM J. PRIESTLY, Jr., formerly superintendent of the Alaska Treasure mine, at Juneau, and of Rhoades-Hall mine, Fairbanks, is now in charge of the Latouche Alaska Gold Mining Co.'s property at Latouche, Alaska.

HAROLD D. TOMPKINS, formerly with the Niles-Bement-Pond Co., of Philadelphia, has accepted the position of mechanical engineer with the Smooth-On Mfg. Co., of Jersey City, New Jersey. He will have charge of the concrete water-proofing department.

Decisions Relating to Mining

MORTGAGOR IN POSSESSION MAY WORK MINE

Where mining property is mortgaged to secure bonds issued by the corporation owning it, both the corporation and the lessees have the right to work the mine reasonably and properly, even though this results in its exhaustion: the rights of the parties being similar to those of a life tenant and reversioner.

Young v. Haviland (Massachusetts), 102 N.E., 338. May 24, 1913.

AMENDMENT OF PARAGRAPH 89, MINING REGULATIONS.

Paragraph 89, Mining Regulations, Department of the Interior, has been amended so as to provide that the charge for publication of notice of application for patent shall, except in Alaska, be no greater than the rate established by the laws of the several states for publication of legal notices, and shall not exceed in any event \$7 for each ten lines of space in a daily publication or \$5 for the same space in a weekly publication.

42 Land Decisions, 204. June 23, 1913.

ABANDONED OIL WELL—FAILURE TO PLUG

A person who drills an oil well and then abandons it without plugging it, so that water rises in the well, enters the oil and gas-bearing sand, and causes the gas flow from a well on adjacent land to cease, is liable to the owner of the land on which the adjacent well is situated for damages both on the common law theory that he has used his own property in such a negligent manner as to injure his neighbor, and upon the further grounds that he has violated a state statute requiring that abandoned wells be plugged.

Atkinson v. Virginia Oil & Gas Co. (West Virginia), 79 Southeastern, 647. Sept. 23, 1913.

MILLSITE—MINING OR MILLING PURPOSES

The use of a millsite as a location for a blacksmith shop and tool house, in which are stored tools, machinery, etc., necessary to run a tunnel upon the mining claim in connection with which the millsite was taken, and as a storage place for supplies needed in development work upon such mining claims, constitutes a use and occupation of the land for 'mining and milling purposes,' such as will entitle it to a millsite patent. Section 10 of the Act of May 14, 1898, reserving a 60-ft. roadway along the shore line of navigable waters in Alaska, contemplates the reservation of only an easement for highway purposes, and is no bar to the location of claims to the water's edge, subject to the roadway easement.

Alaska Mildred Gold Mining Co., 42 Land Decisions, 255. July 23, 1913.

MINING CONTRACT—HELD NOT TO BE OPTION

A contract for the sale of certain mining claims provided that the first party agreed to sell and the second parties agreed to buy claims described in the agreement. Total purchase price was to be \$30,000; \$25,000 of which was to be paid as royalties from the output of the mines. No time was set for the commencement or prosecution of work. The second party did not go into possession, it was alleged, nor work the properties. Suit was brought for the total purchase price after lapse of a reasonable time. The court held that this was a binding agreement, not an option; that the fact that the contract called for royalties did not affect its nature as a contract of sale; that it was implied that the claims sold contained minerals, and if they did not the burden was on the purchaser to prove it as a defense; that it was understood that work must be commenced within a reasonable time by the purchaser.

Pritchard v. McLeod (Alaska), 205 Federal, 24. May 5, 1913.

Recent Mining and Metallurgical Patents

1,073,381.—UTILIZING FINE ORES, FLUE DUST, AND THE LIKE. Hartley C. Wolle and Edward F. Kenny, Westmont-borough, Pennsylvania. Adjusting the moisture therein to make the material semi-coherent and then compacting same into flakes by rolling pressure.

1,073,523.—MANUFACTURE OF SODIUM ALLOYS. Edmund Charles Rossiter, Birmingham, England, assignor to the British Cyanides Company, Ltd., London, England. Heating together a mixture of sodium hydrate, carbon and a metal, and agitating the mixture while thus heated.

1,073,461.—PROCESS FOR THE SEPARATION OF LEAD AND ZINC. Jules Babé, Honfleur, France. A process for the separation of lead and zinc contained in mixtures or combinations of salts or oxides of these metals, which consists in sulphuretting the lead in the presence of a volatile reducing agent at a temperature below that at which the zinc is affected.

1,074,999.—METHOD AND APPARATUS FOR MAGNETIC SEPARATION. Oscar Alfred Zander, Stockholm, Sweden. Arranging ore in a series of overlapping layers or strata and traveling a magnetic field of force transversely of said series and in a direction substantially parallel to that in which the ore is fed to form the layers for separating out of the orebody the magnetic particles thereof.

1,076,397.—ORE SEPARATOR. Hiram J. Stewart and James S. Tucker, Canton, Ohio. A bottom board having its upper face flat excepting for transverse grooves cut therein, the grooves having upright front walls and beveled rear walls, and fabric strips secured across said beveled rear walls, and fabric strips secured across said beveled walls near their juncture with said flat face; and upright sides at the edges of said board.

1,078,199.—METHOD OF EXTRACTING MANGANESE FROM ITS ORES. Friedrich Heuster, Dillenburg, Germany. A method of extracting metallic manganese from its ores which consists in first preliminarily calcining a portion of the manganese ore at a red heat, then proportionately mixing together a quantity of the calcined ore with a quantity of crude uncalcined ore, and subsequently subjecting this mixture to a reducing process.

1,076,700.—ORE CONCENTRATOR. Frank Picone, Tombstone, Arizona. A table having a plurality of parallel transversely disposed riffles upon its upper surface and a second series of riffles arranged between and extending at right angles to said first named riffles, said latter riffles projecting above the upper edges of the transverse riffles and each having one end spaced from the contiguous transverse riffle, and means for reciprocating said table.

1,077,628.—ELECTROLYTIC CONDENSER. Ralph D. Mershon, New York, New York. The combination with an electrolytic condenser, of a transformer connected to the condenser electrodes, means electrically connected with the transformer and the electrolyte to provide an unidirectional electromotive force opposing that between the electrolyte and the transformer, and an independent source of electromotive force in parallel with said means.

1,073,432.—PROCESS FOR PREPARING ELECTROLYTES FOR USE IN THE DEPOSITION OF A METAL OR METALLIC ALLOY. Pascal Marino, London, England. First making a suitable aqueous solution containing a salt of the metal to be deposited, then adding a suitable organic reducing agent to the solution, then heating the resulting liquid and finally, when said liquid has cooled, adding to it a suitable organic reducing agent, substantially as and for the purpose described.

1,075,409.—TREATMENT OF ORES. Nicolas Henri Marie Dekker, Paris, France. Mixing with the dry ore in a closed container, a reagent comprising a metallic sulphate and concentrated sulphuric acid, maintaining the tempera-

ture of the mixture above normal to preserve liquifaction of the reagent, agitating the mass until the non-metallic ore constituents are dispelled, adding water to the residue to form a solution, and separating the metals from the solution thus formed.

1,073,462.—PROCESS AND APPARATUS FOR TREATING SULPHIDE ORES. Ernest Edmund Banes, Strathfield near Sydney, New South Wales, Australia. Manufacturing sublimed white lead, consisting essentially in projecting pulverized lead sulphide mixed with a substantially oxygen-free, combustible hydrocarbon gas through a surrounding layer or stratum of oxygen-containing gas into a heated oxidizing atmosphere and separating the sublimate from the fume gases.

1,078,520.—ORE-SEPARATOR. Fritz Oscar Stromborg, Seattle, Washington. A dry separator consisting of the combination with a fixed horizontal case, having openings at its extremities and in its bottom, and hoppers beneath the latter, of a feeding mechanism for tossing the material to be treated into the rear end of the casing, means for adjusting the angle at which this material is delivered, and means for delivering a blast of air into the opening in the front end of the casing.

1,077,418.—MINING MACHINE. Edward McGowan, Mulberry, Kansas. Carrying means adapted to be freely moved forward during the operation of the machine, cutting means adapted to cut a kerf in the wall of a mine, and supporting means pivoted to the carrying means and carrying the cutting means and having a guard adapted to travel along and bear against the wall of a mine, the bearing surface of said guard being an arc the centre of which is the axis on which the supporting means swings.

1,077,297.—MINERAL SEPARATOR. Marion L. Porter, Silverton, Colorado. A tank provided with an outlet at its upper edge, radially disposed supporting bars fixed at their outer ends to the wall of said tank, a spirally wound plate arranged in said tank, stirrup members depending from said bars and engaging the lower edge of said plate to support the same, and, a deflecting plate fixed to said spiral plate and to the wall of the tank to direct the mineral bearing water through the outlet of said tank.

1,073,468.—FURNACE FOR SMELTING AND REFINING ORES. William Martin Bowles and Charley Osker Allen, Shawnee, Oklahoma. A furnace, means for producing a series of arcs, means for introducing ore above said arcs, a tube leading from said furnace for condensing the metallic vapors, a screw conveyor for scraping the walls thereof and for forcing the condensed product out of said tube, an air jacket surrounding said screw conveyor, an opening into said air-jacket beneath said tube, and a burner disposed at the mouth of said opening for heating the air in the air jacket.

1,075,093.—CYCLIC PROCESS OF EXTRACTING METALS FROM CUPRIFEROUS MATERIALS. Albert Davis, Brooklyn, New York, assignor to Midland Ores & Patents Co., New York, New York, a corporation of Maine. The cyclic process of extracting metals from cupriferous materials, which consists in leaching the material with a solution containing a ferric salt, precipitating the dissolved copper by electrolytic iron, electrolyzing the spent solution under conditions to precipitate iron in highly reactive form and to regenerate the solvent and repeating these operations with other charges of material, utilizing said regenerated solvent as leaching agent.

1,073,543.—ELECTRIC DEPOSITION OF METALS BY FUSION. Arthur Percy Strohmenger, Westminster, London, England, assignor to Slaughter & Co., Ltd., London, England. A process of depositing metal by means of the electric arc, which comprised connecting the work to one pole of a source of electricity, placing above the line along which metal is to be deposited and at an angle to the work a metal electrode coated with insulating material adapted to act as a slag when fused, connecting this electrode to the other pole of the source of current, striking an arc between the work and the end of the electrode, and pressing this end of the electrode down on to the work throughout the continuance of the arc.

EASTERN METAL MARKETS

(By wire from New York.)

NEW YORK, November 26.—Greater confidence is being felt in the condition of the copper market and the general feeling is that it has reached bottom and that an upward movement will follow. Copper stocks are generally low and but little trading is reported. The lead market is weak. The demand is light and prices are generally lower. The buyers are taking only small quantities for immediate delivery and the stocks in the consumers' hands are reported as low. The producers are optimistic, as there is nothing tending toward an increased output. Wet weather in the Joplin district has impeded operations to some extent.

The sources of silver in 1912, according to H. D. McCaskey of the U. S. Geological Survey, were as follows: Placers, 163,955 fine oz., mainly in Alaska and California, recovered by refining placer gold. The yield from dry and silicious ores was 26,363,436 oz. Colorado, Nevada, and Utah made large increases, while there were decreases in Montana, New Mexico, and Texas. From copper ores the output was 18,744,661 oz. This is recovered from electrolytic refining of Lake and blister copper, the product of smelting. Montana, Utah, and Arizona were the largest producers. From argentiferous lead ores the yield was 16,632,377 oz., there being increases in Idaho, Utah, Colorado, and Nevada, that from Arizona showing a decrease. Argentiferous zinc ores supplied 664,421 oz., mainly from Montana and Colorado. Lead-zinc ores yielded 2,810,939 oz. from Utah, Idaho, and Colorado. Copper-lead and copper-lead-zinc ores gave 654,596 oz. from Colorado, Utah, and Montana.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

The copper market had a steady downhill sag last week. At the beginning of the week one of the large consumers predicted that buying would soon be resumed, but not in large amounts, since consumption has in some cases shrunk 25 to 50%. The amounts sold during the week, however, were so small that by November 21 dealers were offering copper at 15c. without eliciting much buying even from abroad. The outlook for cheaper copper is very rosy—to the consumer. The strike at Río Tinto has been settled and production in most districts in this country is at high levels.

Observers of general market conditions predict that there will be no marked general advance in business prosperity until the second quarter of 1914. If this is true, copper is likely to reach considerably lower price levels. Copper exports between November 1 and 20 were 20,734 tons.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

At a recent meeting of the nitrate of soda producers held in Iquique, it was agreed to reduce the production by 19% for the next six months. The decrease in consumption which has warranted this action on the part of the nitrate producers is attributed to the Balkan war.

STATISTICS recently compiled show that during the past twenty-five years the mineral production of Canada has increased from \$2.23 per capita to \$18. Next to agriculture, mining is the greatest wealth producer of the Dominion.

Company Reports

NEVADA WONDER MINING COMPANY

This Company operates at Wonder, Churchill county, Nevada, and the report covers the fiscal year ended September 30, 1913. Results may be summarized as follows:

Development, feet.....	7,150
Total to date, feet.....	18,640
Material hoisted, tons.....	50,114
Ore milled, tons.....	39,118
Total value.....	\$572,359
Extraction, per cent.....	93.2

Metals recovered:

Gold, ounces.....	8,738
Silver, ounces.....	587,211
Value.....	\$535,661

The Company controls a subsidiary concern, called the Churchill Milling Co., and the combined income account is as follows:

Nevada Wonder Mining Co.....	\$ 58,662
Churchill Milling Co.....	175,463
Total.....	\$234,126
Dividend of 10% paid May 20, 1913.....	140,669
	\$ 93,457
Surplus at September 30, 1912.....	622,396

Total.....	\$715,853
Depreciation.....	124,630

Surplus at September 30, 1913.....\$591,223
Of the surplus, \$113,824 is in cash.

The mine superintendent, J. A. Burgess, states that the year was marked by increased development work, as well as an increase in ore sent to the mill. The main shaft was sunk three compartments wide from the 700 to 1030-ft. level, and enlarged to three compartments from former level to the surface. The shaft was timbered with 8 by 8-in. Oregon pine. The greater part of development was done on the 500, 600, and 700-ft. levels. At 800 ft. the cross-cut has been started toward the vein from the shaft, and on the 1000-ft. level the cross-cut has cut the vein and a north drift has been started. The mine generally is in good condition. Several improvements in equipment were made.

THE largest tree in the United States is said to be the 'Mother of the Forest,' a giant redwood in the Calaveras big tree grove in California. It is supposed to contain 140,619 board feet of lumber. There are, however, many claimants for the honor of being the 'largest tree' and the 'oldest tree,' and these claims, according to foresters, cannot always be verified.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

FRUE VANNERS make from 180 to 200 strokes per minute, and the belt travel is from 2 to 6 ft. per minute.

FUME from smelting furnaces will not attack the tubes of waste-heat boilers built in flues, unless the temperature drops very low.

TIMBER MEMBERS of a dredge, which are subjected, alternately to wet and dry, should be sheathed with light sheet iron to prevent this occurring, which results in rotting.

UPPER YUKON steamers carried 1935 passengers from Dawson to White Horse this season. The low rates obtaining led many people to 'come out' this fall who had been in the interior since the discovery of gold.

FRESHLY SLAKED LIME has a much better action on colloidal matter in ores than lime which has been atmospherically slaked over a long period of time, or which has been artificially slaked some time before.

AEROLITES are defined as masses falling to the earth from celestial space. During their flight through the sky such bodies are called meteors and the pieces which fall are meteorites or aerolites (air-stones) or uranoliths (heaven stones).

MOUNT KATAHDIN, in Piscataquis county, Maine, has an elevation of 5200 ft., and is the highest mountain in the state, according to the United States Geological Survey. The average or mean elevation of the entire state of Maine is 600 ft. above sea-level.

OLD IRON RAILS may be used to advantage to protect the sides and bottom ore-bins, where the ore is dumped in from a skip a considerable height above down a chute. Iron or steel plates cut through fairly fast from such impact; but the rails have a long life.

ACID MINE WATER, containing copper, readily attacks rails, bolts, water-tanks, and other things made of iron, which should be kept painted by some acid-resisting paint. The well known P. & B. paint has been very satisfactory for this purpose at the Penn mine, California.

ANNOUNCEMENT has been made at Washington that hereafter certificates will be issued upon final proof in the case of application for patent on mineral claims. This will relieve the applicant from doing assessment work during the time that the Field Division is examining the ground.

SAMPLING ORE from a rock-crusher may be simply and satisfactorily done by punching a few 1½-in. holes at one place in a conveyor-belt which is carrying the ore to bins. The sample falls into a chute, and is further automatically cut down as it falls over several grids as used in an assay office.

SINCE mining began in Alaska in 1880 the gold placers of the territory have yielded 7,488,491 fine ounces of gold, valued at \$154,800,875. These mines have also produced 1,652,016 fine ounces of silver, with a commercial value of \$960,743, according to A. H. Brooks, of the United States Geological Survey.

CONCENTRATE in the collecting boxes in front of vanners, at some mills on the Mother Lode of California, is drained or settled by an attachment to the vanners, which by a few levers, knocks the side of the box or trough for a few minutes. The water collects at one end and is then bailed out, and the hammer taken to another machine.

THIRTY-EIGHT gold dredges were operated in Alaska in 1912, compared with 27 in 1911, according to the United

States Geological Survey. In addition to these, a dozen or more were in various stages of construction. It is estimated that these dredges handled between 3,200,000 and 3,600,000 cu. yd. of material, recovering gold to the value of about \$2,200,000.

LOUISIANA is an important producer of rock salt, in which it ranks second among the states. The salt mines underlie so-called islands, which are really mounds rising above the marsh lands along the Gulf shore in Iberia Parish. The Petite Anse mines, on Avery island, were operated during the Civil War, having been developed in a small way in 1862. These mines were flooded twice, and a new shaft was sunk in 1899. Mining on Weeks island began in 1902. In the value of the total production of salt, which includes the product evaporated from brine, Louisiana ranks sixth among the states.

DISPOSAL of gravel, soil, and sand from a dredge usually results in the gravel being on top as in the half-tone. This is the reverse of what is wanted for resoiling dredged

A PARTLY DRAINED DREDGE POND, SHOWING HOW THE STACKER LEAVES THE FINE AND COARSE TAILING.

land, the gravel should be on the bottom and the soil on the top, so that it could be easily spread over the gravel.

FATALITY RATES among coal mines in a number of foreign countries covering a period of ten years, 1901 to 1910 inclusive, are as follows, according to figures collected by F. W. Horton, for the U. S. Bureau of Mines: Great Britain, 1.36 per 1000 men employed; Germany, 2.11; France, 1.69; Belgium, 1.02; Japan, 2.92; Austria, 1.04; India, 0.96; New South Wales, 1.74; Nova Scotia, 2.65; while the rate for the United States was 3.74. The low fatality rates in the foreign countries is accounted for largely by reason of the fact that coal-mine inspection has been in operation much longer than in the United States. In Great Britain the coal mine accident statistics have been collected, published, and studied since 1851. France, 1853; Austria, 1875; Germany, 1852; and Belgium, 1831.

MILL improvements at the Tomboy mine, Colorado, during the year ended June 30, 1913, consisted in substituting another Wilfley table for a Deister slimer in the grading plant, and moving the latter table to the main concentrator floor; the 12 Frue vanners being at work since 1902 were worn out, and replaced by a similar number of Deister No. 3 slimers; and coarser screens were fitted to the batteries. That portion of the coarse pulp that is sent to the middling plant is reground by two Hardinge conical mills, but this has had a tendency to decrease rather than improve the recovery of free gold by amalgamation. To maintain and perhaps raise the present high capacity of the mill, and secure the best results from amalgamation and concentration due to finer crushing, an installation of two additional Hardinge mills below the batteries is contemplated. Recent experiments, by flotation and electrostatic processes, promise higher recoveries and higher prices for the zinc-middling product. The dewatering plant did good work, and the Dorr settling tanks are fitted with a device, consisting of an additional set of blades and a false bottom, which almost doubles the capacity of each tank. This is to be tried at an early date.

EDITORIAL

NOVEMBER copper production of the Anaconda company is announced as 25,250,000 pounds, the largest since May. The Phelps-Dodge output was 12,556,000 pounds, a slight decrease from the average for recent months.

COLUMBIA UNIVERSITY is to go into mining as well as training miners, having leased a property near Roxbury Station, Connecticut. As the rental is placed at \$1 per year, we suspect that more notes than ore will come up from the shaft.

FILING of a suit against the Golden Cycle Mining Company, by Mr. Charles Butters, with a demand for damages for infringement of filter patents, illustrates the complicated nature of filter-patent litigation at present. The Golden Cycle company recently settled with the Moore Filter Company and now must meet the claims of Mr. Butters. The whole situation illustrates again the unsatisfactory condition of our patent laws.

DECISION by the United States Supreme Court to the effect that in calculating the amount of the corporation tax no deduction should be made for depreciation resulting from mining ore, applies only to the old act. The new income tax, levied in connection with the revision of the tariff law, allows a deduction for depreciation in the case of mining companies of "a reasonable amount not exceeding 5 per cent." Those interested will find details under sub-sections A₂ and G₄ of the tariff law. Further details regarding the judgment just rendered will appear in our decisions department in due course.

ENGINEERS, who are often forced at best to take long chances with their health and with that of their men, are beginning to recognize that it is wise to employ professional soldiers against disease. As a matter of dollars and cents it is cheaper, on work of any scale, to protect the lives and health of the men than to suffer delays and to run the risks incident to amateur sanitation. We print this week an account, written for the layman, of malaria, the common and most annoying disease of new countries. It has been prepared by Dr. H. G. F. Spurrell, medical officer for the Anglo Colombian Development Company, and comes to us from Buenaventura. Dr. Spurrell's papers on the 'Habits of Mosquitos,' that our readers will recall with pleasure, were prepared in the midst of the swamps of West Africa. His knowledge comes thus from first-hand observation and he is of the brotherhood that is making glad the waste places of the earth.

THE magnitude of the business of government in the world as a whole, is shown in the statistics compiled by the Bureau of Foreign and Domestic Commerce. The total annual revenue is stated at \$12,179,000,000 and the annual expenditure at \$12,308,000,000. With this rate of receipt and expenditure and an aggregate national indebtedness of the world of \$42,000,000,000, it would seem that the business of government was on an unsound financial basis.

ANNOUNCEMENT has been made of the details of the transaction whereby the General Petroleum Company is to pass into the control of a British syndicate headed by Mr. Andrew Weir. According to Mr. John Barneson, who with Mr. Eugene de Sabla recently made the arrangements for the exchange of General Petroleum securities for securities in the new corporation, the new Company will be capitalized for \$75,000,000 and will have headquarters in London. The advent of these interests into the California oilfields creates a new and formidable rival to the Standard Oil Company and the Royal Dutch-Shell syndicate. Further details are given in our London letter.

EXPRESSION of sentiment by the 'Citizens Alliance' in the Lake Superior region as embodied in the principles of the organization which are set forth in the pledge of membership, if indicative of the *vox populi*, warrant little optimism on the part of strikers. It is the belief of the members of this alliance that the Western Federation is opposed to good government, good citizenship, and the welfare of the district; that its scurrilous attacks upon the people, its poisonous propaganda of destructive socialism and violence must be brought to an end; that the presence of the Western Federation of Miners is a menace to the future welfare and prosperity of the district; that in the interest of law and order it must go; and that it is the duty of each citizen to exert himself in an effort to bring about an end to the present strike. The unfairness of the demands of the strikers, together with their methods in handling the situation, has apparently incurred the ill-will of the law abiding citizens in the Lake Superior district as in Colorado, and without popular support, unionism cannot expect success.

NATOMAS affairs are treated briefly in our London letter this week and in greater detail in the editorial pages of *The Mining Magazine* for November, just arrived. As is true of many another enterprise, Natomas Consolidated is suffering just now from lack of ready money for completion of projects under way. This would not be matter for especial comment were it not that reports recently made to the bondholders indicate that serious miscalculations as to cost and yield have been made. The former is easily explained by the general and sharp advance throughout the United States in the last few years, and the estimate of yield which now proves seriously at fault, \$3,033,025 as against \$5,139,092, was made, it is to be noted, not by engineers of the staff, but by a consulting engineer chosen by the London bondholders. It is also fair to recall

that the money furnished to the company was \$2,000,000 less than Mr. E. J. de Sabla asked. There has been no criticism of the engineering work and in gold dredging practice Natomas is admitted to be a standard maker. The difficulties in which the enterprise is involved seem the natural results of attempting too big a job with too little money. Possibly the bondholders have been over anxious to deceive themselves and have been allowed to have their own way. Certainly there has been a misunderstanding as to the existence of a prior lien on the property and certainly the consulting engineer who reported to the bondholders with such precision the value of the gold-dredging areas, did not have as full knowledge of the situation as he should. For engineers the lesson would seem to be not to attempt too much in a far country and a specialized industry without abundant local aid. To Mr. F. W. Griffin, the manager, and his excellent staff, we extend hearty sympathy and the hope that the financial skies may soon clear.

Yard Decision Reversed

The famous Yard decision has been overruled, and the Department of Interior has retreated from its position that in advance of patent mineral claims could be declared void by administrative process. This marks another step into the twilight zone that lies between the domains of state and national jurisdiction.

The Yard decision was one of the more famous of the rulings that marked the change in the attitude of the United States government toward the public lands, which followed inception of the conservation movement. It upset many precedents, and its effect was felt in many directions. The decision, made, as was also that which now reverses it, by the First Assistant Secretary of the Department of the Interior, covered a number of points. We discussed it in detail in our issue of July 31, 1909, and also printed, September 11, an illuminating letter by Mr. W. E. Colby in which the bearing of the decision on practice in the oilfields was pointed out. It will be recalled that within the limits of the Plumas National Forest 11,000 acres of land had been located as mineral claims and transferred prior to discovery to Mr. H. H. Yard and the North California Mining Company. The lands were shown to be covered by timber worth \$320,000, and to have yielded gold worth \$3; a mountain pass, now used by the Western Pacific railroad was concerned; and the method of taking the land was one which, by clouding the title, permitted the obtaining of the timber at subsequent sale, at a nominal price. There was much popular feeling that this was a typical case of land-grabbing through taking advantage of technicalities of the law. It was maintained, on the other hand, that the decision operated, as Mr. Stewart White has phrased it, to "change the rules during progress of the game," and public sentiment is sharply against that.

Passing other points concerned, one vital feature of the decision was the assumption by the Department of power to cancel claims prior to patent. It is to be remembered that when a claim is located no notice to any United States officer is required. The mineral

lands have been thrown open to location and entry and anyone, including aliens, may go upon the land and locate claims, without formality so far as the United States is concerned. As between the Government and the individual, no questions arise until application for patent is made. Prior to that date locators must rely upon state courts for protection, though there is a shadowy right of the Government involved in protection of the public domain from trespass. In the Yard decision it was held that for good and sufficient reasons, mainly fraud or plain intent of fraud, the Department might cancel claims even during this probationary period. The same question has come up in other cases. Attempts have been made to hold the Bright Angel trail at the Grand Cañon, by means of a string of mineral locations, and for the apparent purpose of charging toll to visitors. There are many situations where the integrity of a mineral claim is similarly open to question.

We are among those who believe the United States should have power to raise this question; otherwise by doing continual assessment work lands may be held in perpetuity on location only; no application for patent having been made. There are many objections to a general system of such titles, and much may be said for a law requiring notice to the United States government and a system of federal records of locations. However, it is one thing to believe there should be such power of cancellation, and another to hold that it exists. The Supreme Court of California, in the case of *Miller v. Chrisman*, has taken strong ground as to the rights of locators before patent, and even before discovery, and while the Supreme Court of the United States did not comment on that particular phase of the case, it did affirm the decision of the California court.

In the case just decided, that of *J. P. Nichols and Cy Smith* before the Land Department, certain placer locations on unsurveyed lands in the Wallowa National Forest were held by the local officers and the General Land Office to be null and void, after hearing held upon charges by the Forest Service that there were no discoveries of mineral, and that the claims were not held in good faith for mining purposes, but for speculation. On appeal, the First Assistant Secretary ruled that so long as these parties had not filed mineral applications the Department had no jurisdiction over their locations; that the proper forum for the determination of the validity of the mining locations is the courts; and he said that the decision rendered in 1909 in the Yard case "is entirely indefensible, whether viewed from an administrative or legal standpoint"; and that to the extent that such decision might mislead citizens or officers of the government "into an unwarranted invasion of private rights, it would be repugnant to good administration as subversive of law." The Yard case and all others of like tenor were therefore overruled, and the Government resumes the position it had always held prior to that decision. This places matters in the shape that we urged they should assume, in our editorial comment at the time the original decision was rendered; namely, that decision of such matters, involving the good faith of the applicant, are better made in open court than

before an administrative bureau. It is to be noted that this does not touch such a case as that involved in the Cunningham decision where patent was refused. Apparently, however, the Cunningham claimants, if content to go without patent, could have continued to hold their claims by doing annual assessment work, and relying on the courts for protection against trespassers. The ambiguity of such a situation is but another argument for general revision of the mining law. Why be content with uncertain titles, and why face litigation when Congress has both the right and the duty to enact explicit statutes covering all such matters?

Large Scale Gold Mining

Juneau is fast becoming one of the great mining centres of the world. Across Gastineau channel the Treadwell group of mines has long been famous for the low grade of the ore and the great scale of the operations. The new central shaft is equipped for handling 5000 tons per day from a depth of 3000 feet, and even more extensive operations may be expected. This, however, is about to be surpassed on the main land. In Silver Bow basin immediately back of Juneau is a great gold-bearing lode that has been worked on a small scale for a number of years. Last year Mr. D. C. Jackling and the late A. F. Holden became interested in the Alaska Perseverance mines at the south end of the lode and the Alaska Gold Mines Company was organized to finance large scale operations. Through its subsidiary company, the Alaska Gastineau, a 6000-ton mill is now being built and the mine is being rapidly prepared to furnish ore for this plant. Probable extensions are already forecasted. The central portion of the lode is owned by the Alaska Juneau Gold Mining Company, in which Mr. F. W. Bradley and associates have a controlling interest. We gave some account of this property in our issue of May 31 and have the pleasure of printing this week an authoritative statement as to the mining problems involved, written by Mr. Bradley. He tells much of technical interest and gives an insight into the conditions that permit planning work on the basis of milling 12,000 tons per day for 100 years. Truly such gold mining is of a new order. North of the Juneau is the Ebner property which, after numerous vicissitudes, has now been brought into some semblance of order as regards titles, and is under option in the interest of the United States Smelting, Refining & Mining Company. The ground is to be tested by a long deep-level adit, such as has been driven at the Juneau and the Perseverance, and, if development is favorable, another great producing unit may be expected. According to present plans, a total daily production of more than 20,000 tons may be expected at Juneau within the next four years. This will furnish work for something more than 30,000 men and will require a generation of 40,000 horse-power, besides furnishing a market for machinery and supplies of the first order. All this may not be so romantic as "finding another Cripple Creek," but the establishment of a practically permanent industry of this order in Alaska means more for that territory.

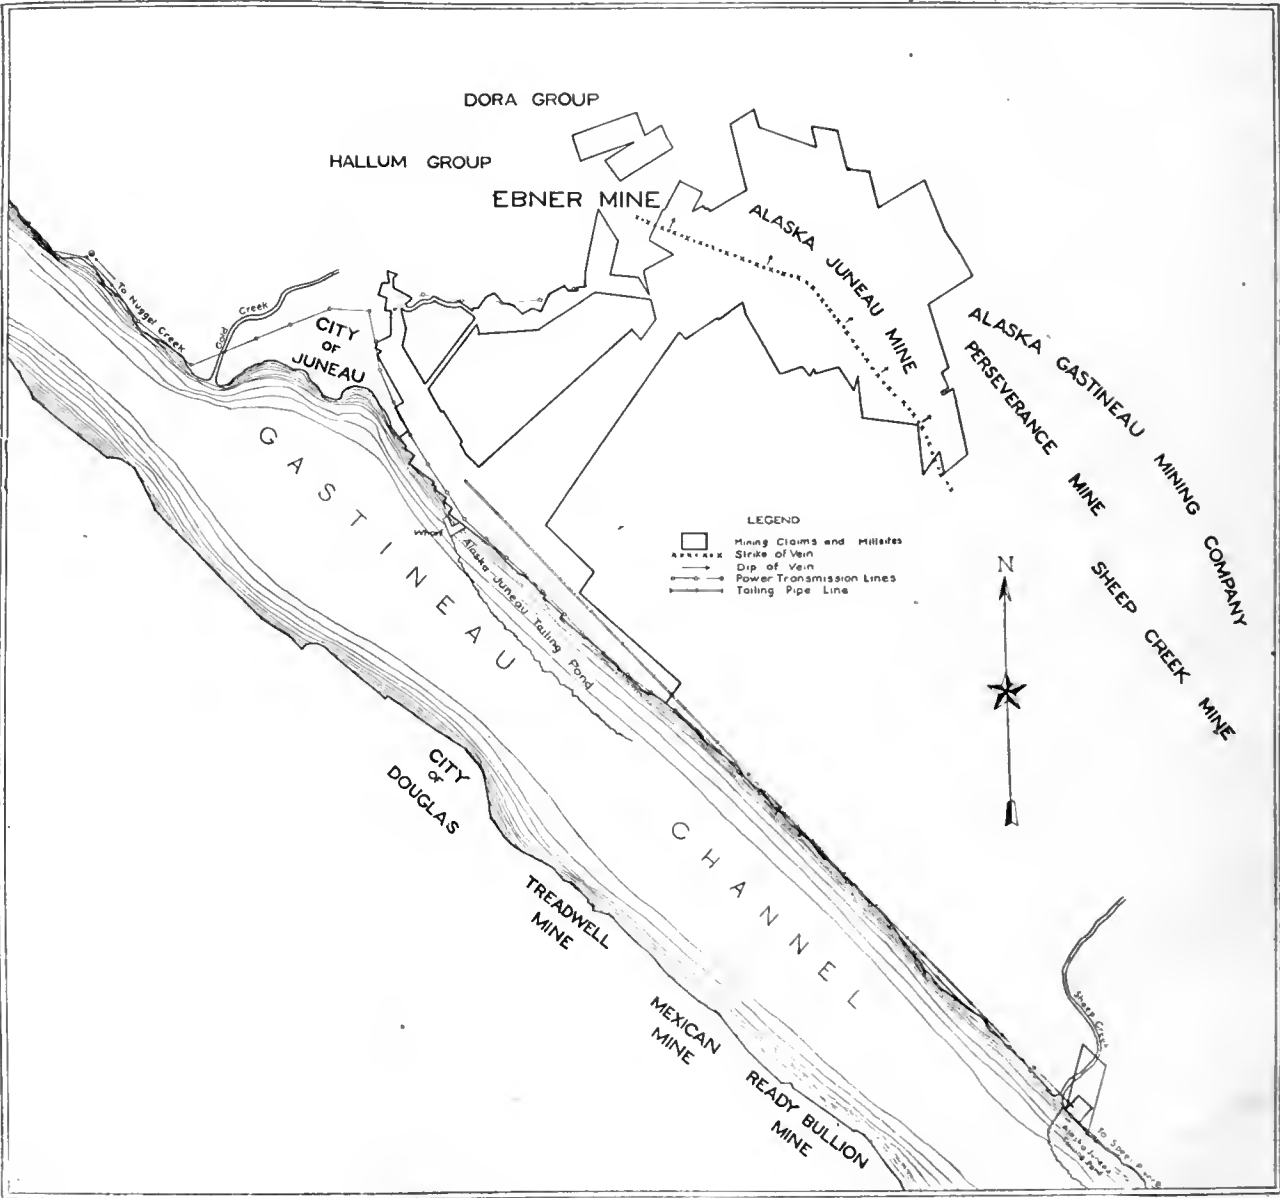

Plans of the Alaska Juneau Gold Mining Company

By F. W. BRADLEY

The development and equipment plans of the Alaska Juneau Gold Mining Co. now under execution, and which involve mining and milling a gold ore considered at one time to be worth no more than \$1.25 per ton, are the result of several years study of peculiar local conditions and problems. It was

from a point on Gold creek about two miles back from the town of Juneau and at an elevation of 420 ft. above sea-level; which work was originally planned in 1899, started in 1909, but was not definitely arranged for until 1910.

This main cross-cut has now been advanced for a

MAP OF A PORTION OF THE MINING CLAIMS, MILLSITES, AND OTHER PROPERTY OF THE ALASKA JUNEAU COMPANY.

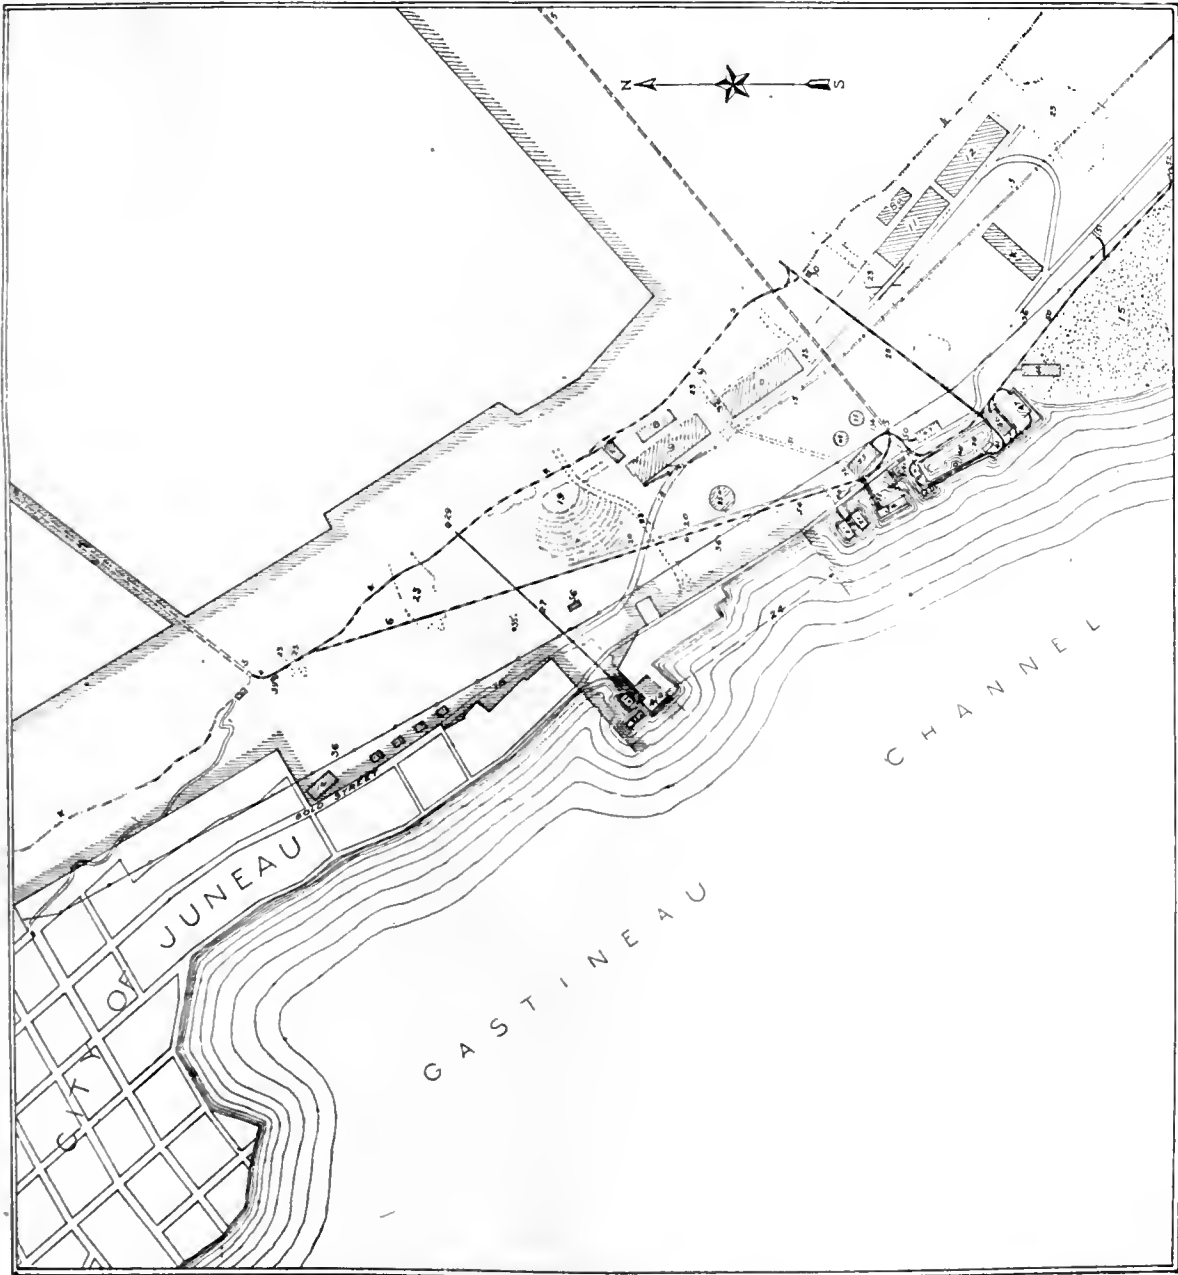

evident from the beginning that a tremendous tonnage of proved value would have to be developed, as to bring the operation to a successful climax involved the mining of a very large daily tonnage and treatment in mills placed at salt water. Milling operations the year round in Silver Bow basin (an elevation 1200 ft. above sea-level, being the lowest building spot on the Company's mining claims) are impractical even on a small scale, because of climatic conditions, and on the scale commercially demanded are out of the question for reasons entirely aside from climate. The very first proposal involved the deep development of the vein by running a cross-cut

distance of 6538 ft. to a point where a raise is now being driven to reach the surface in the shortest possible distance. This raise will be about 800 ft. long to the floor of Silver Bow basin on the hanging wall side of the vein; while if driven in the vein to the apex of the latter at the surface, the raise would be more than 2000 ft. long.

By the time the raise is completed, 30 stamps of the first mill unit will be ready to begin milling the best available ore (selected from a comparatively high-grade streak in the vein) in order to make the mine help pay for its further development. At the same time, 10 additional stamps (arranged accord-

ing to the flow-sheet hereinafter referred to) will begin test crushings to determine the accuracy of the sampling and assaying of the ore already exposed by the cross-cut, to prove the value of any ore that may be exposed by the raise, and to discover

mill working five months each year for the past 15 years on ore mined by open-pit work along the crop-pings of the Alaska Juneau vein. Confidence in the persistence of the vein and its value is also based on milling results obtained by the small Ebner mill on

MILLSITES OF THE ALASKA JUNEAU GOLD MINING CO.

1. Private trail to mine; 2. change-house; 3. adit No. 3; 4. flume and tram line; 5. main working or sea-level adit; 6. incline tram from main adit; 7. rock-house No. 2; 8. ore-bin; 9. first mill unit; 10. second mill unit; 11. third mill unit; 12. fourth mill unit; 13. tailing pipe-line; 14. slime and cyanide plant; 15. tailing pond; 16. office; 17. cottages; 18. private road to mills, extension of Gold street; 19. picked waste dump; 20. sluice-box to convey waste to barges; 21. waste barges; 22. waste barge wharf; 23. lines of snow and rock slides; 24. sawmill reservation; 25 and 26. gridirons; 27 and 28. incline tramways; 29 and 30. hoists; 31. fresh-water pipe-line; 32. salt-water pipe-line; 33. power-house; 34. coal wharf and bunkers; 35. fuel-oil tank; 36. power-transmission lines; 37. boat-float; 38. salt-water pump-float; 39. fresh-water tank for Juneau fire protection; 40. salt-water pipe connection for city of Juneau; 41. main wharf; 42. barn; 43. wood shop; 44. machine shop; 45, 46, and 47. warehouses; 48. gasoline storage; 49. circulating water tank; 50. industrial tracks; 51. powder adit; 52. powder house; 53. coal conveyor; 54. oil pipe-lines; 55. transformers; 56. compressor.

what defects, if any, exist in the present adopted flow-sheet.

The Vein

The vein where cut by the main adit has a right angle thickness of about 500 ft. with an average assay value of about \$2 per ton. Although this is better than any of the surface developments, it is believed that this width and value will persist for considerable distances both longitudinally and vertically. This belief is based upon the results of a 30-stamp

the continuation of the vein westerly into the adjoining Ebner property, and by the milling results obtained by the old 100-stamp Perseverance mill on the continuation of the vein easterly into the adjoining Perseverance property. In 1910 when the active development of the Alaska Juneau property was undertaken, extensive open-pit mining was planned for summer work, and for winter work reliance was placed upon finding comparatively narrow widths in the vein that would yield by selective underground stoping \$1.45 per ton; but as the vein where exposed

by the cross-cut should yield \$1.70 per ton, it is now expected that an average recovery of \$1.45 per ton will be obtained from the entire vein when mining underground 6000 tons per day. This can be done at a total cost of not to exceed 80c. per ton, which cost per ton will be somewhat reduced when eventually winning 12,000 tons per day.

Mining

Mining will be done under a combination of the Douglas Island methods with the caving system developed in the adjoining Perseverance mine by the former superintendent, J. R. Mitchell, with the expectation of securing at least 100 tons of broken ore per machine-drill shift, as against an average of 31 (29 to 34) tons in the Douglas Island mines. This difference in duty per machine-drill shift is due entirely to the difference in composition of the two veins; the Alaska Juneau being a slate vein with loose or free quartz stringers and some metagabbro dikes between a greenstone foot-wall and a schist hanging wall, while the Douglas Island vein is a solid, hard, tough dike of diorite with frozen quartz stringers without parting or selvage between the quartz and the enclosing rock as in the Alaska Juneau slate vein. The Alaska Juneau ore is very much easier to drill than Douglas Island ore and will break with a less consumption of powder per ton. Also when blasted or caved, the Alaska Juneau ore in the bottom of a stope will in time, because of air slaking and the superimposed weight of additional ore broken or caved from the back of the stope, crumble and crush into pieces small enough to go through chutes into ore cars; whereas, the Douglas Island ore after being blasted from the back of a stope has to be both bulldozed and broken by sledges in order to pass similar openings.

Haulage System

The trolley haulage system to be eventually installed in the present cross-cut and over the tramway from it to the millsite will handle 6000 tons per day. In order to handle a total of 12,000 tons and over per day, a sea-level adit is now being driven. This, starting immediately from the millsite on the shore of Gastineau channel (an arm of the Ocean), will be 9500 ft. long to reach the vein at a point 400 ft. vertically below its development by the present cross-cut. For this winter's milling work, the ore hauling will be done by a gasoline locomotive.

Milling

Although the slate and the metagabbro each carry gold to the amount of from 25 to 85c. per ton, practically all the easily recoverable gold is in the quartz stringers which are worth about \$6 per ton. Experimental work has demonstrated that the mill feed can be profitably enriched by sorting out and roughing out the waste, even though there is some loss in the gold contained by the waste, plus that contained by some ore thus discarded. In the rock-crushing house, it is expected that about 20% of the waste will be trommeled off with very little handling. This is because the quartz occurring as loose or free stringers is more friable than the slate and will break into smaller pieces when going through a rock-

crusher with consequently more waste than ore passing over the end of the trommel; and a very little hand-sorting work on a waste stacking belt at the end of the trommel, will prevent the loss of any substantial amount of ore.

The milling proper may eventually be done in four units of 150 stamps each and to build each unit and to prepare the mine for supplying each mill unit with 3000 tons of ore per day would require at least a year's time, or at least four years' time for the four units having a total capacity of 12,000 tons per day. Of the 40 stamps of the first unit to begin dropping this winter, 10 will be used as a pilot plant. Each stamp of the pilot plant will crush about 17 tons through a 1/4-in. mesh screen and 3 tons will be by-passed each stamp, thus making a total duty per stamp per day of 20 tons. The pilot stamps will be followed by two Wilfley roughers, one Chilean mill, amalgamating plates, and two Wilfley concentrators. From the 200 tons of crushed and by-passed material from the 10 stamps, there should be eliminated about 30 tons of slime, then the two Wilfley roughers should eliminate about 40 tons of waste, leaving 130 tons for the Chilean mill. The crushed product from the Chilean mill will be classified and each class (70 tons of slime being eliminated) will go direct to its own amalgamating plates from which it will go over its own Wilfley concentrators which will remove the sulphides. All slime and all sulphides will go direct to the cyanide plant—the slime for direct treatment and the sulphides to be tube-milled and then treated.

The principal value in the ore is due to free gold, there being less than 2% of sulphides, which have an assay value of less than \$30 per ton. This is practically all gold, but includes some silver, lead, and copper value. Consequently the concentrates will not be so easy to treat as are the straight iron pyrite concentrates of the Douglas Island mines.

The situation demands and requires wholesale mining methods to secure low costs per ton, but as to milling methods, it may be more profitable to do selective work than wholesale. That is, it may be more profitable to do very much more sorting at the rock-crushing house than is now contemplated. The operation of the pilot portion of the first unit on ore from the deep mining to be begun this winter, will determine definitely whether the milling is to be wholesale or selective, and this in turn will determine just how the remaining portion of the first unit should be completed.

To provide for the very large tonnage that must be handled in order to earn a satisfactory profit, wharves and slips have been arranged for waste barges which can take out and discharge in the ocean any large quantities of waste that may be sorted out of the mill feed, providing selective milling is decided upon. If, on the other hand, wholesale milling is decided upon, then the resulting fine tailing will have to be deposited locally to the extent of the available storage space and eventually they will have to be piped to storage space farther out in Gastineau channel beyond Sheep creek, as shown by the map. The tailing will be discharged from the mill at an elevation of 170 ft. above sea-level, which elevation affords ample grade for carrying it long distances in each direction along Gastineau channel.

Mining and Milling Costs

Below is a comparison between the ascertained average costs per ton in the four Douglas Island mines and the estimated costs per ton at the Alaska Juneau when the latter is working on the same scale as the combined Douglas Island mines.

	Douglas Island.	Alaska Juneau.
Mining:		
Development, stoping, and general	\$0.72	\$0.24
Underground and surface tramming, hoisting, and pumping..	0.23	0.16
Total mining	\$0.95	\$0.40
Milling:		
Labor	0.09	0.06
Supplies	0.04	0.04
Power	0.04	0.05
Miscellaneous and general.....	0.08	0.05
Total milling	0.25	0.20
Concentrate treatment	0.08	0.07
Plant construction and other costs.	0.12	0.13
Grand totals	\$1.40	\$0.80

Battery water and water for some power will be carried from Gold creek to the millsite in a flume that parallels the Gold creek adit tramway line. Any small deficiency of battery water during extreme cold spells in the winter season will be made up by pumping salt water. For the present any deficiency in the Gold creek water supply for power purposes will be made up by an auxiliary steam plant; but eventually, hydro-electric power will be transmitted from Nugget creek, about 15 miles distant. Also, it may be necessary to eventually transmit hydro-electric power from Speel river, about 45 miles distant.

No provision whatever has been made for housing or boarding employees (who will total about 400 for each mill unit or eventually about 1600 in all), because the tramway adit immediately behind the city of Juneau practically brings the mouth of the mine within the city limits, where, no doubt, ample and suitable accommodations will be forthcoming as required. It has been found at the Bunker Hill & Sullivan mine in Idaho, the feeling of loyalty of employees to the Company is much improved by in no way infringing upon their absolute right and freedom to use their own time and money as they please. Besides, a contract has been entered into between the Alaska Juneau company and the city of Juneau whereby the Company is freed from city taxation on its plant within the city limits in consideration of its furnishing a supply of both fresh and salt water for fire protection. This contract is further reinforced by the moral obligation that the Company will not go into either the boarding house or store business to the extent of endeavoring to force its employees to discriminate against similar establishments in the city of Juneau. The importance of this feature of the matter arises from the fact that it is expected that operations on this mine will continue for a hundred years or more.

Phosphate rock has been opened near Abingdon and Marion, in Washington and Smyth counties of Virginia.

Consolidated Gold Fields of South Africa

In the report for the year that ended on July 31, the following general statements are made: "In the report of last year it was pointed out that, taking the gold-mining industry of the Witwatersrand as a whole, the recovery per ton crushed has of late shown comparatively little variation from year to year, so that any increase in the average rate of profit earned must generally be derived from reduction of working costs. This view is borne out by the results obtained during the year that ended July 31, 1913. The total output of the Witwatersrand gold mines was 8,698,681 fine ounces of gold, representing an estimated profit of £12,750,000, as compared with 8,432,379 fine ounces and an estimated profit of £12,200,000 for the preceding year. But for the effect of the recent strike the results of the year under review would have been better. These results were obtained by crushing 26,333,530 tons of ore giving an average recovery value (on the basis of 8s. per fine ounce) of 27s. 9d. per ton, with average working costs of 18s. 1d. per ton (or, excluding Gold Fields companies, 18s. 11d. per ton), leaving an average profit of about 9s. 8d., the figures for the last three years being:

For year ended	Recovery.	Working costs.	Profit.
July 31, 1911.....	27s. 10d.	17s. 10d.	10s. 0d.
July 31, 1912.....	28s. 1d.	18s. 5d.	9s. 8d.
July 31, 1913.....	27s. 9d.	18s. 1d.	9s. 8d.

"In the case of the mines of the Gold Fields group, it is to be noted that in four of the crushing mines the grade of the ore encountered has fallen during the year, and that, though every effort has been made to counterbalance this by cheaper working, the reduction made in working costs, though substantial, has not been sufficient to maintain the average profit per ton at the rate shown twelve months ago; the average working profit for the group having been 5s. 10.574d., as against 7s. 2.550d. last year."

The following figures show the essentials of the year's work both for the Rand as a whole and for the Gold Fields mines:

TRANSVAAL			
	For year ended July 31, 1912.	For year ended July 31, 1913.	
Total gold output, fine oz.....	8,857,398	9,114,219	
Value output at £4.24773 per fine oz.	£37,623,834	£38,714,742	
Tons of ore crushed (including tons treated by direct cyaniding).....	26,157,972	27,260,951	
Estimated mining profits from gold.	£12,523,000	£13,165,000	
CONSOLIDATED GOLD FIELDS GROUP			
	For year ended July 31, 1912.	For year ended July 31, 1913.	
Actual total gold output, fine oz....	946,520.181	936,022.616	
Value of output as shown in companies' books	£3,975,167	£3,936,596	
Value output at £4.24773 per fine oz.	£4,020,562	£3,975,971	
Tons of ore crushed	3,616,330	3,978,882	
Mining profits from gold (excluding expenditure on machinery renewals and replacements).....	£1,304,143	£1,170,019	
Total profits (including sundry revenue and revenue from accumulated slimes)	£1,384,566	£1,265,428	

Malaria—Its Effect on Work and Workmen

By H. G. F. SPURRELL

It is my intention in this paper to discuss malaria as a disease. That is to say, I mean to deal with various aspects of a disorder in the health of the human being, not with the microscopic animal which causes that disorder, nor with the mosquito which transfers it from one man to another.

There is such a high probability that a mosquito will sooner or later transmit the parasite, which causes malaria, to every white, who spends any length of time in the tropics, that, whenever malaria is a subject of general conversation, the interest centres mainly around the measures for suppressing mosquitoes or escaping their bites. Yet, after all, it is the results, which follow the introduction of the parasite, which are really important; and now that the part played by the mosquito in transmission is established, and its importance never again likely to be neglected, I think it would be well if a little more thought were given to the disease itself. Malaria is not the only or the most deadly disease of tropical lands. A man who goes to tropical America may get yellow fever, and if he does he is quite likely to die within the week. A man who goes to the East may get Kala-azar, and if he does he will certainly die within a few months. But there is hardly anywhere in the tropics where a white man can stay for any length of time without being able to count with practical certainty upon contracting malaria and suffering more or less severely from its effects. Malaria, although it is not the most spectacular of tropical diseases, is probably the one which most hinders the development of the richest parts of the world.

Influence of Malaria

Malaria means different things to different people, but it always means something very bad to everyone connected with a mining company. To the company's employees who work the mine it means shifts missed, pay lost, and a probable curtailment of their working lives. To the mine manager it means the presence of a medical officer who is an expensive infliction and is continually saying that employees and sometimes the manager himself are not fit to work when their services are most required and often when to his untrained eye there is no obvious reason why they should not make an effort to do at least something. Not content with this the medical nuisance has a way of insisting upon vexatious regulations, which upset the harmony of life, and of requiring alterations in the housing of the staff which make the costs mount up. To the medical officer, malaria means not only work, he is there for that, but constant strife and anxiety. To the shareholders it means a drain of endless expense and a periodic recurrence of mysterious disasters.

The layman who is wise does not endeavor to close with his enemy himself; he allows his professional soldier, in this case the medical officer to do this for him; but he may have his interest aroused in the cause of his misfortunes to the extent of wish-

ing to understand something of its working. If he goes to medical text-books he finds that previous medical knowledge is necessary to grapple with this particular problem, while if he consults a medical man he is liable to lose patience: the fellow so often appears to be contradicting himself. It is therefore no easy task that I have the temerity to undertake.

First, malaria is not one disease: it is at least three. Secondly, though each of these diseases depends on a very definite sequence of events, the circumstances in which these events take place may produce a bewildering variety of manifestations. I will endeavor to describe the base essentials first, in their simplest circumstances.

Suppose you go, if I may put the matter personally, to visit or work in a mine in a malarious country. I am assuming here that you have never been in a malarious district before. The mine may be one where every recommendation of the company's medical advisors has been acted upon. The staff is housed in mosquito-proof buildings, the native dwellings are kept at a proper distance from the camp, quinine and good advice are given free. You think that on such a property you will be safe. Unfortunately to get there you may have to pass through dangerous country which is not under the company's control. You have to stop at hotels, travel by boats, and hang about customs houses where every sanitary rule is ignored. If you are new to the country and language, the native servants who take you through the bush may, probably will, by their management of your camp equipment and food, endeavor to ascertain by experiment the limits of your patience. What they actually prove is the extent to which you are susceptible to the insect and waterborne diseases of the country.

Symptoms

If this part of your journey does not take more than a day or two, you may, after you have been a week on the property, flatter yourself that either the things which bit you were not infective mosquitoes, or else that your powers of resistance are high. But at the end of a week or thereabout there comes a day which begins with a feeling of uneasiness. You cannot say you feel ill, but it is much as if you were being dragged out by misguided friends to go skating after you have lived for many years in a place where the winters are too mild for the ice to bear. You feel unsteady, you are sure you will not enjoy yourself, and you wish the treat were safely over; but you are determined to get through the day without disgracing yourself. You next feel as though the ice had given way under you and after total immersion in freezing water you had scrambled out and were being struck at short intervals by gusts of a bitter wind. There is no question of resistance now; teeth chatter loudly, your limbs shake violently, and you feel desperately ill. Your friends hurriedly put you to bed and pile blankets

on you. If you have a kick left in you, you ask for more blankets, and, notwithstanding, your shivering fits shake the whole bed. Yet cold though you feel yourself, if anyone else took your temperature he would find that it had run up to 104°F. or 105°F. You, however, have other things to engage your attention. You remember how, the day before, you saw a negro trying to split a log of wood. He stood over it and swinging his axe aloft buried the blade in the end of the log with a resounding thump. Then he tugged and shook at the handle of his axe to get it free for another blow. You feel now just as though the devil himself were trying to split your head in the same way. Then comes a change: the shivering ceases and you feel overpoweringly hot and fling off the blankets for which you clamored before. Finally a profuse perspiration breaks out all over your skin, which hitherto had felt about as dry and harsh as a hot brick. The sweat pours off you in streams and soaks your blankets and mattress through; but in yourself you feel wonderfully better and very likely soon to drop off to sleep.

Next day you feel almost yourself again and quite able to go about your work as usual. But on the following day at about the same hour another attack like the first comes on you and runs the same course. This continues. On alternate days the same series of events, the preliminary malaise, the cold stage, the hot stage, and the sweating stage occur in regular order taking from first to last about eight hours to run their course; and after a week or two of this you are an anemic wreck.

Protection Against Malaria

For the purpose of giving a clear picture of the disease, not of frightening anyone who may be going to a malarious country, I have described an untreated case of malaria. If effective protection against mosquitoes can be secured it is not necessary to get malaria at all. If a daily dose of quinine is taken as a prophylactic the malaria parasites which are introduced into the blood may die before they have time to give rise to symptoms of disease, or, if some of them do survive, the malady they produce is the ineffective work of debilitated cripples. But what surprises the victim of such an attack as I have described is to hear, when a medical man arrives to diagnose his case, that he has been suffering from the form of malaria known as 'benign tertian.' "Tertian perhaps," he says: "the second attack came on the third day from the first, the third attack on the third day from the second, and so on." Call a disease which affects you on alternate days "tertian" if you like, but why "benign"? What other forms of malaria are there which are not "benign" and how can they be worse?

'Benign tertian malaria' has not, however, been misnamed. Its name distinguishes it from the two other kinds of malaria, one of which is called 'quartan malaria' because the second attack comes on the fourth, not the third, day from the first; the other is called sometimes 'subtertian malaria' because its periodicity is less clearly marked than that of benign tertian, sometimes 'malignant tertian' because it is infinitely more dangerous to life. I shall endeavor to show that these distinctions indicate differences

which really exist, and are of practical as well as scientific interest.

It will be well to establish at first the points which the three diseases have in common. All three are due to the activity of animal parasites, not to bacteria, which are vegetables. It is not necessary to my purpose to describe the structure or development of the malaria parasites, but it will be as well to say here that they can easily be recognized under the microscope in specimens of a patient's blood, and that in this method of examination the species causing the three different diseases can be distinguished from one another by any observer of ordinary skill. But it will be worth while before discussing the symptoms of malaria further, to describe how the microscopic animal causes the disease. I should like to attempt this by means of a homely illustration. Suppose you took half a dozen mice, and, having corked up each one tightly in a bottle, with a piece of cheese and enough water and oxygen to keep it alive for 48 hours, arrange the six bottles on a shelf in your room with an automatic contrivance for breaking them simultaneously at the expiration of that time. Until the moment arrived when the bottles were broken you might live within a yard of them and forget their existence. But all this while within the closed spaces the mice would be converting the oxygen and water and cheese into new and malodorous compounds; and when the bottles were suddenly broken and mice careered wildly around your room looking for fresh hiding places, you would be sickened by the overpowering stench of their accumulated products. It would require some hours for cleaning and airing before the room would be habitable again. This is the kind of a way in which the malaria parasites produce the symptoms of disease. Each young malaria parasite enters and establishes itself in a red blood corpuscle. This minute body with its minute inhabitant circulates in the blood together with the other unaffected corpuscles; but all the time it is degenerating, for the parasite is digesting its substance until nothing is left of it but a containing membrane. As a consequence of feeding on the interior of the corpuscle the parasite grows till it is many times its original size. It attains maturity assuming something of the shape of a raspberry, and, when finally the corpuscle bursts and it is turned adrift in the blood stream, the segments of the microscopic raspberry separate and each, as a young parasite enters a different corpuscle to start a fresh life cycle. The young parasites do not cause the attack of fever directly: the symptoms I described above are due to the waste products of their growth, while feeding within the corpuscle, being suddenly released into the blood stream from their containing envelope. This has been proved by taking blood from a patient during an attack of fever, and, after filtering it through porcelain to get rid of parasites and all solid constituents, injecting it into the veins of a healthy man. He suffers at once from a single attack of fever, but does not contract malaria.

Various Forms of Malaria

The particular features of the different kinds of malaria depend upon the specific characters of dif-

ferent parasites. The one which causes benign tertian malaria completes its life cycle with a blood corpuscle in 48 hours, so the attacks of fever occur approximately at the same time on alternate days. That causing quartan malaria requires 72 hours and accordingly the attacks recur with intervals of two days between. These two diseases, however, have an important feature in common due to the fact that all the parasites in the body reach maturity at about the same time and consequently the fever, which marks the liberation of their waste products, takes the form of well defined attacks with a sharp onset and definite duration. The parasites of subtertian malaria on the other hand, though their life-cycle takes about or a little under 48 hours, are far less uniform in their growth and do not reach maturity simultaneously. Hence the attacks of fever are not so well marked, but usually last longer. A man with subtertian malaria usually has a definite rise of temperature on alternate days; but the degree of fever reached is not as a rule so high as in benign tertian, while on the intervening days the temperature, though it usually falls considerably, often does not quite come down to normal. In technical language, subtertian malaria tends to be a remittent fever, while benign tertian and quartan are intermittent.

The reader may still be wondering why the disease in which the most spectacular paroxysms of fever occur should be called 'benign.' The name in a comparative sense, however, is well deserved. This type of malaria in spite of its sensational manifestations rarely endangers life, at any rate in its early stages, and it yields, as a rule, quickly and easily to treatment. Much the same may be said of quartan malaria except that it yields less readily to treatment, is harder to shake off, leaves greater debility behind, and is a serious complication where any other disease is also present. Subtertian malaria, on the contrary, is a dangerous disease which is liable to take a 'malignant' form, when it may prove fatal, if not immediately and effectively treated. Even when it does not develop 'pernicious' characters and endanger life, its effects are often grave and far reaching.

Subtertian Malaria

Subtertian malaria has two aspects, both of which it is particularly important to keep in mind. I have already mentioned that the parasites which cause this disease are less regular and uniform in their habits than those of the benign tertian, and that the patient, accordingly, often appears less acutely, but more continuously ill. Their other peculiarity is that they render the corpuscles in which they develop, adhesive, and liable to stick to the walls of bloodvessels instead of flowing on with the blood stream. As they approach maturity, they most of them get anchored in the deeper parts of the body. This sometimes occurs very locally when it may cause more or less complete obstruction of the circulation in particular organs, and give rise to effects varying according to the organ. Where the organ is healthy it is bad enough. A sound intestine, for instance, may be sufficiently weakened in this way for other germs, hitherto powerless, to start an attack of dysentery.

But where the efficiency of the organ is already impaired, as in a heart hampered in its action by the effects of previous valvular disease, comparatively slight interference with the blood supply may precipitate a disaster. All too frequently the obstruction occurs in the smaller bloodvessels of the brain. People notice that a man is stupid and becoming incoherent, and they charitably suppose that he is drunk. They then find he gets drowsy and loses consciousness, and conclude that he is sleeping off his intoxication. On the following day they are horrified to find that he is dead. At the post-mortem it is demonstrated, by means of the microscope, that the smaller bloodvessels of his brain are full of malaria parasites and the pigmented debris of broken-down corpuscles.

Mild Forms

One might well suppose that the comparatively mild form, which subtertian malaria not infrequently takes, was of importance chiefly because the disease might on that account remain unidentified and untreated until there occurred some such catastrophe as I have described. This of course is true, but it is not all. A man acknowledged to be suffering from subtertian malaria may feel not too ill to struggle on with work in which he is deeply interested; and unfortunately he may also appear to others capable of doing it satisfactorily. A greater mistake is hardly possible than to entrust important work to a man who has not completely recovered from subtertian malaria. Although such people may not seem to have their faculties impaired, they are peculiarly liable to commit errors of judgment, and naturally the more responsible the position they hold and the more deservedly they are trusted, the greater the harm they may do. Many tactical errors, shipping disasters, extraordinary mistakes in estimates, and apparently unaccountable suicides have been due to men in charge of affairs refusing to admit that they were too ill to carry on their duties and continuing to struggle with facts whose bearings they could no longer recognize clearly. Apiece with this blunting of the critical faculty is a tendency to be unreasonable and cantankerous. The patient refuses to admit that he feels ill, and is fractious under treatment, particularly when the treatment urged is rest. Where he is in subordinate position this is bad enough, though then he can be ordered to rest, or, if he is obliged to work, what he does can possibly be checked afterward either by someone else or by himself later when he is recovered. But it is a very serious matter when the head of affairs becomes unreliable without being aware of it, especially when his subordinates do not recognize that the firmness of character, which perhaps has hitherto been regarded as one of his most useful qualities, has been replaced by pig-headed stupidity.

From the description I have given, malaria, in whichever form it may be present, might appear to be an easy disease to recognize, and it might be supposed that no one who had any experience of it, could very well be afflicted without knowing it. Yet though this is true of a typical case, there is no other disease which shows a regular tertian or quartan periodicity—it is quite the reverse with many of the

eases which one actually meets. For instance, the patient may have been infected twice and having two stocks of parasites in his blood, each maturing independently on alternate days, have an attack of fever every day. If one stock is a tertian and the other a quartan, every other attack of fever will be repeated on three successive days. When a man is infected with both benign tertian and subtertian parasites there is considerable danger of the subtertian element being overlooked and the case regarded as one of the less serious disease. These difficulties can all be cleared up, the kind of parasite identified, and the different stocks in their different stages of development sorted out, by means of the microscope. But the patient often makes this difficult by taking a dose of quinine before he goes to a medical man, and, though malaria is not cured so easily, this will probably make the parasites disappear from the superficial circulation, for a time, and delay the possibility of accurate diagnosis, though not the need for immediate treatment.

Susceptibility to Poisoning

Then some people, particularly those who are having their first attack, are more susceptible than others to the malarial poison. The microscope may show that they are infested with a single stock of benign tertian parasites, which are maturing regularly on alternate days, yet the constitutional disturbance caused at each attack of fever be so severe that it has not passed off before the next arrives, and the patient is continuously ill. On the other hand, the microscope may show that a man has the parasites in his blood running their usual course, but not present in sufficient numbers to cause attacks of fever. Such a man may appear to be merely anemic and gradually declining in health, and the medical man who diagnoses malaria is met with the incredulous question, "Is it possible to have 'fever' without a temperature?" While some people are inclined to attribute most of the misfortunes of life to malaria, others see in the manifestations of this disease the effects of all manner of unlikely causes. The man who loves his whisky believes his symptoms are due to his not drinking enough of it, while his counterpart, the rabid teetotaler, sees in everyone else's ailments the effects of alcohol. Many an attack of malaria has been taken for sunstroke, and obscure cases of ill-health often become the starting point of dietetic faddism when their cause could have been found with the microscope. Consequently malaria in its comparatively less serious forms may steadily undermine the health of a community without being recognized. The occasional cases with well marked attacks of periodic fever, are believed to be the only instances of the occurrence of malaria, and the anemia, sleeplessness, general debility, and depression of vitality are attributed to other causes, usually that vague abstraction, 'climate,' and not treated. While in this way the indefiniteness of the disease may lower the working efficiency of a community and lead to the wastage of constant invaliding, a similar indefiniteness, in the more serious cases, may lead to mistakes in diagnosis, which, by delaying treatment, endanger valuable lives. I have taken care to emphasize the milder,

less definite aspects of subtertian malaria because it is so important not to overlook them; but it must not be forgotten that this disease has its severe forms in which high temperatures and bilious vomiting make up a picture remarkably like that of yellow fever. When special malignant features are produced by large quantities of the affected corpuscles lodging in particular organs, a number of serious conditions may be simulated: pneumonia, dysentery, and apoplexy are only a few of them.

Complicated with Other Diseases

Yet here another point must be emphasized, namely, that malaria may complicate other diseases as well as simulate them. It does not exclude other diseases, and it stands to reason that if malaria is bad by itself it is no better when associated with some already grave condition. The man with tuberculosis of the lungs or a defective heart, has no vitality to spare for coping with malaria as well, and should not be exposed to the risk. Should such a man get malaria into his system he may be sure that whenever either his original trouble or his added malaria becomes active, the other disease will take advantage of his depression to light up afresh. A man who has left a malarious country for some time and believes either that he has shaken off the disease or possibly that he has never contracted it, is very liable to develop a sharp attack should he meet with some accident or require a surgical operation of any kind. In fact, whenever a man who has been exposed to the infection, suffers from any derangement of health, it is always as well to examine his blood, with the microscope, in order to make sure that his present illness is not complicated by a recrudescence of malaria. There is, of course, the converse of all this. In every place where a great reduction of malaria is effected, the death-rate from other diseases is reduced. One disease in particular deserves special mention here. Blackwater fever is no longer believed to be a form of malaria; but though acknowledged to be a separate and well defined disease, there are few who will deny that the vast majority of cases, if not all, occur in people who have lived for some time in a malarious country neglecting precautions against malaria and not being sufficiently treated for the attacks.

After Effects

And now may I be permitted to use, once again, the personal method? I have described how bad you can feel in an attack of benign tertian malaria; I want next to consider what may happen to you after it. If you are treated properly you will speedily gain relief from your symptoms, and, if the treatment is thorough, you will have no more trouble unless you are reinfected. As a matter of fact, people who go from a temperate climate to the tropics often do not become entirely free from infection for a year or so after returning home. After all symptoms of malarial fever are gone a few parasites continue to lurk in the system, and whenever the vitality is lowered by such accidents as another illness, overwork causing severe fatigue, exposure to bad weather, privations, or indiscretions of diet, or even mental worry and anxiety, they seize the opportunity

your lowered powers of resistance offer, to increase and multiply with deleterious effects to your health. These may take the form either of a succession of attacks of fever on alternate days similar to, though not usually so severe as, your first experience, or, if the parasites do not at once gain the upper hand, of progressive anemia, sleeplessness, irritability of temper, and general wretchedness. How far either may go depends on how soon your condition is recognized and treated. I may here give a word of practical warning. When you return home from the tropics you almost inevitably make a considerable change in your way of living. You may land back in winter and meet with cold weather to which you have become unaccustomed. This, besides being bad in itself, necessitates your wearing thick clothes which also feel unfamiliar and oppress you by their weight. You probably, without any intemperance, relax your care in the matter of diet. And almost certainly you have a good deal of business, both your own and your company's, to transact, which involves much traveling about and fatigue. It is remarkable how many people, who have shown no signs of malaria during the latter part, perhaps even the whole of their stay in the tropics, have a bad bout almost as soon as they reach home. Yet after you leave the tropics you will lose your malaria. With treatment you lose it quickly, but even without treatment malaria tends in most cases to die out in the course of two or three years, though there are people who, having once been in the tropics, attribute to malaria every ailment that troubles them for the rest of their lives.

Power of Resistance

With almost all diseases, it is noticeable that some individuals have naturally higher and some lower powers of resistance than those of the average man, and that these powers of resistance vary at different periods of life. The negroes who live, without medical interference, in an African swamp, have, so to speak, come to terms with the malaria parasite of their district. Their children are all inoculated by mosquitoes at an early age. Those whose tolerance of the poison is low die, and do not transmit their susceptibility to the next generation: there are not many of these, as in the course of ages the stocks with low resistance have died out. In a certain small percentage of the children the parasite cannot be found, and it is possible that these have such high powers of resistance that the parasite cannot survive in them: there are not many of these, either, as the advantages of immunity over tolerance are not great. The average child harbors the parasites for a few years; but its tolerance is great, and its health is not much disturbed. By the time it is about ten years old it has in most cases developed such a degree of immunity that the parasites cannot live in its blood. But should the children of any of those negroes who have removed to a non-malarious country, be exposed to infection when adult, they prove susceptible. There is no complete racial immunity. In South America, for instance, some negroes spend most of their lives in high, well drained country, where they run little risk of infection, and others

reside in towns in which sanitation is more or less defective. In addition, many dose themselves intermittently with quinine. Consequently here malaria is not uncommon with a black skin, for early inoculation is not universal nor is the disease always neglected till immunity is acquired. Where negroes suffer from malaria the mortality, especially among their children, is high.

Susceptibility of White Races

Among white races of northern origin the susceptibility is great, particularly in childhood. The unstable nervous system of the child is peculiarly liable to be attacked by subtertian malaria, when convulsions and all too often death result. Yet one, not infrequently, may still meet in the tropics with elderly men who went to the country before the proper way to guard against the disease was known, and who now take no precautions against malaria. Yet they enjoy robust health, and may even tell you that they never have suffered from fever, though they have buried many men who did. One sometimes finds them men of high character and ability; but one is more likely to notice the cases in which their way of life is reckless, to put it mildly, and their capabilities seem so limited that one wonders how they ever attained the responsible positions they hold. These are the men of high resistance. Of the many men who go to tropical climates, some are invalided and some die; others, either by care or good powers of resistance, last their time, but nevertheless are glad to return to life in temperate latitudes after a while. Others again seem to come to no harm whatever they do, and prefer to live out their lives in an easy-going land. In the old days men of this last type rose to be managers of the concerns in which they were employed, by sheer staying power. Other employees and other managers came and went, or came and died, but they lived on. In course of time, not only did they get to know the business and the country and the people, but both at home and on the spot it was realized that they could be regarded as permanent; and some of these old reprobates are there at the head of affairs to this day. They have seen many men die, and when young men, newly out, take them for their models and aspire to attain a like eminence by drinking level with them, they see them die, too: though often not from want of good advice from the very men who do not find it necessary themselves to practice what they preach. This individual difference in powers of withstanding disease is a factor which employers, who need a white staff in malarious lands, cannot afford to neglect until they have brought the malaria under control. Every man's first visit to a malarious country is an experiment. It may prove that he can live and work where others cannot, in which case he can command his price in future: it may end in his being sent home again before he has paid for his passage out.

But the question of susceptibility in malaria is not a question of malaria alone. It is also a question of tolerance of quinine. The man who professes scepticism of the efficacy of quinine merely reveals his ignorance of established facts. But

there are individuals who suffer from most unpleasant symptoms whenever they take even a small dose of quinine. People who cannot take quinine should not attempt to live in the tropics. It is also well to bear in mind that there are times when women stand quinine very badly.

Treatment

Mention of quinine brings me to the subject of treatment, in which it plays an important part. All I intend to say here about treatment is that when properly carried out it is wonderfully effective. In this short paper I have touched the fringe only of a very big subject. My object has been to show that, on the one hand, malaria is a perfectly definite thing, on the other hand, its manifestations are so varied that only a trained observer provided with the proper appliances can be sure of recognizing it behind all its effects. I have also tried to show that malaria is capable of impairing the working efficiency of a community in all manner of ways, which range from causing what is almost sudden death and acute illness to chronic ill health and progressive decline. I would again emphasize by separate mention that malaria may be responsible for impaired judgment in individuals which may result in anything between slight inaccuracy in office work and a terrible disaster. I have also endeavored to show how malaria, where neglected, is liable, as a complication, greatly to increase the seriousness of other diseases and of injuries due to accidents. If my endeavors have been successful, I think my contention will be conceded that the prevalence of malaria is one of the greatest obstacles that can stand in the way of a country's development. The moral is surely that all matters connected with the detection, prevention, and cure of malaria should be placed in competent hands, and that those hands should not be restrained by mistaken ideas of economy or hampered by the interference of uninformed people.

Before an individual travels, or goes to live beyond the reach of medical assistance, he can obtain much useful information regarding the care of his health from anyone competent to instruct him, and should not neglect to do so. But where a community has to live in the tropics, where a white staff has to be maintained to supervise native labor, it is a fatal mistake to economize in sanitary organization and to allow cases of sickness to be dealt with as they arise by a plebiscitum of amateurs. Malaria is not the only cause of fever in the tropics, and early recognition and correct treatment are quite as important in other diseases as in malaria. Moreover, malaria, even when diagnosed correctly by a layman, is often difficult for him to treat successfully; while many of the worst cases simulate other conditions so closely that he is not likely to recognize and treat them as malaria at all. One of the results of this is waste of money. It is true that the sanitation and medical supervision required by a white community in the tropics may seem expensive, especially if the numbers are small, but the saving in reduction of time lost through acute illness, the gain in increased individual efficiency through improved health, fewer invalidings, and

greater continuity of work, and the advantage of being able to employ a larger proportion of whites to supervise the native labor, may not only mean a gain in money, but actually make possible an enterprise which would not otherwise be practicable at all. This can no longer be disputed now that we have before us the impressive object-lesson of Panama. When the real lesson of Panama dawns on the civilized world, we may see an exploitation of the tropics by the people of temperate climes comparable in its far-reaching results with the occupation of the New World by the peoples of Europe.

Retardation Phenomena in the Solution of Gold and Silver in Aqueous Cyanide Solutions

According to I. I. Andreev in a recent number of *Zeitschrift für Elektrochemie*, the solubility velocity, AG, for gold divided by the percentage of KCN concentration is fairly constant at very low KCN concentration and reaches a maximum at 0.25% KCN concentration. In 1 to 50% KCN solutions the solubility velocity is proportional to the concentration of the O_2 present. Weakly ozonized O_2 has an accelerating effect on the solubility velocity for Au. If the O_3 content exceeds 4%, only a temporary acceleration occurs; the surface of Au becomes brick red, due to oxide formation, and a definite retardation in the solubility velocity follows. H_2O_2 has an identical effect, very slight amounts accelerate, increasing quantity retarding. Some visible oxide formation with accompanying retardation takes place in air under certain conditions even in KCN solutions of 0.01 to 0.05% concentration. This phase is being further investigated: PbO_2 and MnO_2 individually and alone have no effect on the solubility velocity of Au in KCN, but in the presence of H_2O_2 or O_3 , O_2 is given off and marked acceleration of the solubility velocity takes place. No Au oxide layer was observed. Analogous experiments were carried out with silver. Increasing amounts of H_2O_2 or O_3 give accelerating effects in much greater degree than with gold and the solubility velocity diminishes only with comparatively high O content. Combination of O_3 and H_2O_2 increases the solubility velocity 25-fold.

Shipments of ore from the Missouri-Kansas-Oklahoma field for the forty-four weeks ended Saturday, November 8, represent a total value of \$13,166,684. The estimated value of the ore in the bins is \$1,000,000, making more than \$14,000,000 worth of ore produced from the zinc, lead, and calamine mines during the year to date. In the production of zinc sulphides, Webb City is first, Joplin second, and Miami third. Webb City also is first in lead, Miami second, Joplin third. For calamine, Granby is first and Duenweg second, with Spring City third.

North Dakota lays no claim to importance as a mineral producer, yet the state's output of minerals in 1912 was valued at more than \$1,000,000. The yield of lignite was 499,480 short tons, valued at \$765,105. Clay products were valued at \$231,245.

Geologic Work on the Mother Lode

A petition was recently addressed to George Otis Smith, director of the U. S. Geological Survey, asking that a re-study of the district be made by the Survey. It was signed by many of the prominent operators and engineers. In the course of his reply, Mr. Smith said:

"As you doubtless know, the Survey has in the past carried out extensive geological investigation in the Mother Lode region, resulting in the publication of geologic folios covering the lode for most of its length, together with much of the country on either side. It has always been intended to complete and round off this work on its economic side by the preparation of a comprehensive monograph on the gold veins of the Sierra Nevada, particularly those of the Mother Lode. This project has been deferred because the part of the Survey's appropriation available for work in metalliferous regions has never sufficed to meet all demands, and it has been necessary to confine activities to those districts in which work was most urgently needed and most heartily appreciated. An important factor in determining the relative urgency of various proposed projects is the disposition of the mining men in a district toward geologic work. Fifteen years ago, when the work for the Mother Lode folio was done, the attitude of mining men along the Mother Lode was not generally favorable to scientific study, or was at best apathetic. In some mines the geologist was welcomed, in others he was tolerated, in a few he was hampered by unnecessary restrictions, and to one important mine, entrance was refused to the federal geologist. As the best results are possible only where the mine owners coöperate fully with the geologists, it is not surprising that during the past few years other important districts, in which the work of the Survey was earnestly desired by the local men, and where it was apparent that every facility would be given to the visiting geologist to do his work well, should have been given precedence over the Mother Lode of California. I am pleased to see from the names appended to your letter that the general spirit toward scientific study is so favorable, although I miss from your list the original Amador Mines Co., the Keystone Consolidated Mining Co., the

Argonaut Gold Mining Co., the Kennedy Mining & Milling Co., the Oneida Gold Mining & Milling Co., the Zeila Mining Co., the Lightner Mining Co., the Gwin Mine Development Co., the Melones Mining Co., the Harvard Mines (Buckminster), the Rawhide Gold Mining Co., the App Mining Co., the Dutch Gold Mining Co., the Jumper Gold Syndicate, and a number of other companies, all of which are or have been important producers. If the companies mentioned are also in favor of the proposed work, such fact will go far to insure its successful completion, and the Geological Survey will undertake the investigation as soon as funds are available for it, and will carry it to completion as fast as is consistent with sound scientific work.

"In conclusion, I wish to express my satisfaction that prominent men practically interested in the Mother Lode, desire its investigation under the direction of the Geological Survey, and to say that, if the desire is shared by most of the important companies not represented in your letter, or if at least they will not withhold from the geologist who may be assigned to the work free entrance to their mines and such data as he may require, I shall be pleased to detail one or more of the regular Survey staff to investigate the veins of the Mother Lode as soon as money can be set aside for that purpose."

[A number of companies referred to by the Director as not signing the petition were represented on it by the personal signatures of officers.—EDITOR.]

The production of tungsten ore in the United States during 1912 was equivalent to about 1330 short tons carrying 60% of tungsten trioxide, valued at \$502,158. The output for 1912 was larger than that for 1911, when 1139 tons, valued at \$407,985, was produced. The total amount of tungsten produced in the world in 1912 was 9115 short tons.

The Talisman mine, New Zealand, produced \$106,000 from 4400 tons of ore during October. A strike of coal miners has cut off the fuel supply for the mine and mill.

Dredges operating on the Gold Coast of West Africa, treated 2,204,501 cu. yd. of gravel in 1912, yielding 12,478 oz. gold, equal to nearly 10c. per yard.

Melting Points of Copper Alloys

The U. S. Bureau of Mines has recently studied the melting point of commercial alloys and the determinations below were obtained by A. B. Norton,

with aid from S. J. Popoff, at Cornell University, under the direction of W. D. Bancroft, of Cornell University, and of H. W. Gillett, of the Bureau of Mines. A brief report upon the work has been published as Technical Paper 60 of the Bureau.

Alloy.	Composition desired.				Composition by analysis.				Number of duplicate determinations.	Melting point (liquidus)	
	Cu %	Zn %	Sn %	Pb %	Cu %	Zn %	Sn %	Pb %		°C.	°F.
Gun metal	88	2	10	4	995	1825
Leaded gun metal	85½	2	9½	3	85.4	1.9	9.7	3.0	6	980	1795

Mining in Algeria

By AN OCCASIONAL CONTRIBUTOR

Algeria, France's premier colony, although not her oldest, is rich in the various minerals, notably phosphates, iron, zinc, lead, copper, antimony, and quicksilver. In a report recently issued on the mineral wealth of the country and the stage of its development and exploitation, it is stated that 68 concessions have been given for the exploitation of these minerals. It is known that there are large deposits of iron in this country, but particular attention is given to the more valuable metals. The output of zinc, for example, with a tonnage of one-tenth that of iron, is worth more, and its production is constantly increasing. In the case of lead, the production remains practically stationary, while copper is produced only to a very limited extent.

In the department of Oran are situated the mines of Fillaoucen Gar-Ronban (argentiferous lead) and Hassi-ben Hendjir (copper); none of these mines, however, are being worked at the present time. Zinc and lead deposits which are rich in calamine are being worked at Djebel Masser. At Mazis the calamine passes into blende at depth. These deposits are all being worked by one company and have a good record as producers.

Province of Algiers

Of the 14 mines in the province of Algiers, only 4 are being worked at the present time, namely, the Djahamama, Gerrouma, Ouarsenis, and the Sakamody mines. Considerable exploration work has been done and a large territory has been prospected with divers results. At Guerrouma, which is 50 gm. from Algiers, the blende and galena are found mixed with the Senonian marls. The mineral sulphides mined by the Bou-Mebren company in this locality in 1912 amounted to 2308 tons. The calamine deposits at Djahamama are found in ferruginous sands between the Lias limestone and the Silurian sandstone. The company working these deposits has obtained but little ore from them to date. The most important mining work being done in the region is at Ouarsenis. The concessions for this work, which cover an area of 2558 hectares, were granted in 1890. The calamine is found deposited in the upper beds of the Liassic period. These deposits have been worked at four different places, known as the Grand Pic, Abd-el-Kedn, Bell Kairet, and Rokka-el-Etba. Wherever these deposits have been found they have been in the form of pockets. At the Grand Pic property, work is being done on five rich pockets at the present time. These deposits are about a half metre wide and vary in length from 40 to 90 m. At Abd-el-Kedn there are two deposits of calamine which are strongly impregnated with baryta. Another deposit 30 m. long and 5 m. wide carries baryta blende. The Bell Kairet and the Rokka-el-Etba deposits are unimportant.

The Ouarsenis deposit is particularly rich in smithsonite, which is found mixed with oxide of iron; it has also yielded argentiferous galena with a little blende. The mineral content, after calcina-

tion, varies from 34 to 55% zinc. The galena ore of the Grand Pic contains 64% lead and 900 gm. silver per ton. At the Tarat-el-Ref, the galena carries 72% lead and 663 gm. silver. The mineral is transported from the mines in carts to Orleansville. During the year of 1912 there was produced 7118 tons.

Constantine

The ore deposits are more numerous in the province of Constantine than in any other province of Algeria. There are more than 80 known deposits in this province. Concessions have been granted for working 50 of these. One of the principal exploiting companies is the Guergour, which holds concessions for working the Ain-Roua, Kef Semmah, Djebel-Anini, and Bankedema deposits. The minerals exploited by this company between the towns of Setif and Bougie are silicates and carbonates of zinc, carrying some sulphur. They appear in the form of accumulations in two deposits and in the form of veins in the others. Mining is done either by pits or stopes, the deepest of the pits being 80 m. The mineral that is mined is shipped to Bougie or Tixter-Tocqueville. This company employs 200 men at the mines. The equipment includes a large washing plant and a dam is now being constructed to insure a supply of water for hydro-electric power.

The Ain-Aiko company is exploiting a splendid deposit of calamine at its property, 20 km. from Oued-Zenati station, on the Guelma-Constantine railway. The ore assays from 40 to 45% zinc, and the calamine carries about 58% zinc. Large ore reserves have been blocked out at the Amarko mine. The calamine is shipped by rail to the village of Montcalm, 8 km. distant, and is then wheeled in barrows to Oued-Zenati. The equipment includes four 60-ton and four 12-ton furnaces, the latter for treating the high-grade ore and concentrates. There are also a washing plant, workshops, and a central power station, equipped with a 280-kw. generator driven by producer gas-engines of 115 hp. The washing plant is equipped with two plunger pumps which are driven by electricity. There are from 400 to 500 workmen employed by the Ain-Aiko company, for whom living quarters are provided by the company. The usual conveniences requisite to the comfort of a small town have also been provided, together with railroad communication with the outside world.

Vieille-Montagne Company

The Vieille-Montagne company, between the years of 1872 and 1878, acquired the deposits of Hammam-N'Bails, called the Nador. This property is situated on the right bank of the Seybousse river, south of the Guelma-Constantine railway. The Nador calamine deposit is at least 10 m. wide, and is interstratified with beds of limestone. At depth, and particularly toward the eastern extremity of the property, antimoniate of iron takes the place of

the nadorite which constitutes the gangue of the calamine. The calamine ore when calcined yields from 30 to 35% zinc. The antimoniate of iron contains 40% antimony, and the nadorite yields from 40 to 60% of lead and antimony. Mining is being done here in two pits at a depth of 70 m. The Company has two calcining furnaces on the ground. The mineral is taken by carts to the station at Nador, 16 km. distant, from which point it is sent by rail to Bone. In 1912 the Company shipped a large amount of antimony to Antwerp, but since that time it is being practically all shipped to France and Belgium.

The deposits of Djebel-Soubella or Bou-Thaleb are fast becoming exhausted, which was to be expected, as they consisted of narrow veins in the Jurassic limestone. Lead is found at Bou-Thaleb in the form of galena and carbonate. The property is equipped with four crucible furnaces and one reverberatory in addition to a washing plant. The mineral is carried from the property to Melsong, on the Alger-Setif railway, which is 55 km. distant.

The Société du Djendi

The Société du Djendi, like the Vieille-Montagne company, is exploiting carbonate of zinc deposits in the Djendi Guesta district. Near the village of Ampere, south of Setif, there are six parallel calamine deposits in the marl and limestones of the Upper Cretaceous period. The calamine here is of uniform quality and contains, after calcination, 50% zinc. Great hopes are entertained as to the future of the Oued-Bou-Doncka deposits, which are situated west of Philippeville, where the mineral is said to contain from 40 to 50% zinc. Work on these deposits has been recently started.

The Ouasta Mesloulia company is operating in the country near Tunis. The ores here contain calamine and lead carbonate. At Mesloulia the accumulations of calamine are associated with lead and copper. The mineral is sorted and washed at Claire Fontaine and sent to Bone by rail. The output of Oneste is carried in carts 30 km. to Souk-Ahras and sent by way of Bone to Antwerp. The products of Mesloulia supply the works of Couéron (Loir-Inferieure), France.

There is only one copper concession that is being worked at the present time, which is at Tadergount, 34 km. southeast of Bougie. The mineral is found here in three veins and the metal content varies from 15 to 25%. Only a small force of men is employed at these properties. At Heliopolis Guelma there was a concession of 1160 hectares granted in 1905 for ground reported to carry 35% silver. This ground will be exploited in the near future. Near the Jemmapes, between Bone and Philippeville, a concession has been granted for 1336 hectares of ground carrying pulverulent cinnabar. This property yielded nothing in 1912. A mercury furnace was recently erected, and it is expected that the property will develop into a producer.

Mining is being actively conducted in the province of Constantine. There are about 15 applications for concessions before the authorities at the present time, and a number of applications for permits to prospect have also been asked for.

The concessions given for zinc deposits and the like are of considerable extent, and some of them date as far back as 1872, as the N'Bail-Kef-Semma, which had a production last year of 10,238 tons. Some concessions have been given since 1900, most of them being granted in the year 1908.

As there are no reduction works in Algiers, the minerals have to be exported in a crude or semi-crude condition. Belgium takes five-sixths of the calamine exported, and Great Britain and Germany share the balance. All of the lead is shipped either to France or to Belgium. There is no mineral fuel in the district of any importance. There are two lignite concessions, which to date have not been exploited. This does not mean that the field is hopeless, for petroleum has been found within the confines of the country, notably at Dahra, east of Mostaganem and near Claire Fontaine and Constantine. Permits and concessions have been given, notably to an English group, for the prospecting and production of petroleum. The Olan Oil Co., Ltd., has sunk wells as deep as 475 m. and found a permeable base at 416 m., indicating petroleum. It is stated that another well has encountered a petroleum formation at 83 m. depth. It is not necessary to state that, in the event of petroleum being found in the country in any quantity, there is no reason why a metal manufacturing industry could not be established here. This, however, is a matter of the future.

Costs at the Yuanmi Mine

This gold mine is in Western Australia, and during the past fiscal year a total of 64,350 tons was mined and treated at the following cost:

	Per ton.
Ore extraction:	
Breaking ore, including ore from development....	\$0.90
Filling stopes	0.13
Tramming and raising	0.72
Total	\$1.75
Ore treatment:	
Crushing	\$0.09
Ore transport	0.06
Milling	0.50
Treatment by vacuum-filter	0.58
Fine grinding sand	0.72
Precipitation and melting	0.13
Disposal of residue	0.05
Total	\$2.13
Realization of bullion	0.11
Grand total	\$3.99

Gold Yield of West African Mines

In October the principal outputs were as follows:

	Tons.	Value.	Profit.
Abasso	8,600	\$72,000	\$9,700
Ashanti	11,119	177,000
Broomassie	2,400	65,000	5,000
Tarquah	5,160	71,000	14,000

Gravel washed at the Lena Goldfields property, Siberia, from October 1, 1912, to September 30, 1913, totaled 850,500 cu. yd. The gold yield was 335,348 oz., valued at \$6,000,000.

Iron Ore Deposits of Chile

By CARLOS VATTIER

*In my publications on the subject of iron mining and metallurgy, which have been presented to the public during the past two years, especially those papers presented at the meeting of the Iron and Steel Institute at London and Leeds, in October of last year, the richness of the Chilean deposits was discussed. However, in my last expedition, accompanied by Nicomedes Echegarai, I have, through the courtesy of the mine owners, been able to make a

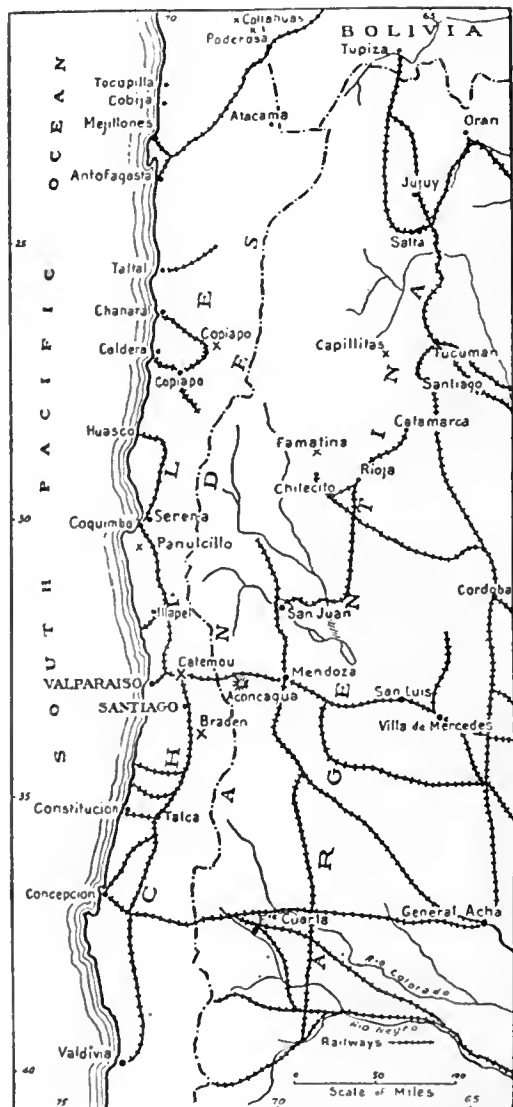

works, and surface deposits which can be seen on the declivities and summits of the mountains. In the Department of Chañaral at an altitude of over 600 metres above sea-level, there are to be found maritime deposits of recent geologic age. The iron deposits here, as a result of the violent upheaval, are seen in various forms. In some places they appear as true stratified deposits dipping into the mountains, and in others as massive deposits lying on the barren granite or porphyry. The depth to which these deposits extend can only be determined by drilling. The large superficial showings of oxidized ore which are accompanied by smaller ones intimately associated with them, are evidences of the existence of bedded and blanket deposits at depth. In some localities bedded and vein deposits of great length and richness are to be seen. This class of deposit is found to consist of a pure oxide of iron to great depths. There is always the probability that these oxides of iron are a cap which covers deposits of copper minerals.

Copper-Iron Minerals

Copper minerals in association with iron manifest themselves in various forms. Sometimes at a few metres from the surface, the iron mineral will carry two, three, or even a greater percentage of copper (as is the case at Pueblo Hundido, Carmen, and other localities), and such an ore carrying considerable copper will extend to great depths. At other places are found fissures and small veins of high-grade copper in the main body of the iron oxide or in that zone lying between the vein or bed proper and the wall rock, but without extending into the deposit proper. One can be certain of not finding copper mineral in the iron ore in these occurrences. Copper is also found as phosphate and sulphate in certain zones of a deposit, but will disappear as length or depth is attained. These variations in the quantity and quality of the iron minerals in the various deposits make it necessary to prospect the property thoroughly before it is possible to make an absolute statement as to their value as deposits of commercial importance. In special reports on the geology of the country in which these deposits are found, it is possible to find some information as to their prospective importance and the best means of exploiting them.

Geographical Position

A study, which is as yet not completed, of the iron deposits of Chile, makes it possible to a certain degree to establish a general rule correlating the importance of these deposits from a commercial, industrial, and metallurgical standpoint with their situation in different parts of the Republic. Up to the present time there has not been found any deposits of high-grade iron ore in the southern provinces of Chile. Only low-grade limonite has been found in that region. The deposits of importance begin to appear at Parral in the province of Linares and ex-

MAP OF CHILE.

more thorough study of conditions and the possibilities of these deposits. I might add that my opinion, previously expressed, regarding the classification and formation of these deposits has been confirmed.

It is evident that many of the iron deposits of Chile were at one time under the sea and were afterward raised into what now is known as the Cordilleras and with the decomposition of these first deposits there have been formed beds, pockets, stock-

*Translated from *Boletín de la Sociedad Nacional de Minera*.

tend north from this point. In the provinces of the central part of the Republic, are deposits of a good grade of iron ore, but these are generally not very extensive, and their position is so far distant from the coast that for the present at least, they cannot be exploited at a profit for the export trade. The deposits of greatest importance are situated in the provinces of Coquimbo, Atacama, and in the southern part of the province of Antofagasta. From this southern zone of the province of Antofagasta to the north, little is known at the present time. However, there are known to exist some deposits (as at Mejillones) of iron ore, which always contain copper or other metals.

The most important result of the latest studies has been to permit correlations of great precision between these deposits and to arrive at conclusions as to their general trend. The general course of the deposits is north and south, and these lie at somewhat fixed distances from the coast. Three systems of veins have been recognized to date. Naturally, the respective distances of the orebodies from the coast vary with the irregularities of the coast line and the conditions under which the particular part of the mountains containing the deposit was elevated. In a general way it may be stated that the first system of veins, which are found beginning at the sea shore on the west coast, extend to the east a distance of from 10 to 12 kilometres. The deposits at Tofo, Juan Soldado, Romeral, Huachalalume, Cifunchos, Cachina, Potrero (Taltal), Mejillones (Cobrizos), and others may be mentioned as belonging to this system. The second system is from 20 to 80 kilometres to the east and embraces the following deposits: Infiernillos, Dorado, Tunillas, Cristales, Algarrobo, Yeso, Depositos de Bodegas i Chamonate (department of Copiapó), Varillas, Sierra Aspera, and others. The third zone is from 100 to 150 kilometres to the east and includes the following deposits; those of the provincia de Santiago, Yacimiento de Illapel i Combarbalá, San Marco (departamento de Elqui), Potrero Seco (departamento de Copiapó), Púquios, and others. It will be interesting to connect these various deposits with lines on a geological map.

Domuño Deposits

Before speaking of the important deposits in general, I will give a brief description of the deposits at Domuño, which is near the port of Quintero in the department of Valparaiso and which was recently studied. On the side of the mountains at an elevation of 400 metres above sea-level and eight kilometres from the coast, in the argillaceous schists there appear some veins from 0.4 to 0.2 metres in width of specular and micaceous oxide of iron. On this vein there was sunk a small shaft to a depth of two metres and lower down an adit was driven into the deposit a distance of 12 metres. It was found that with a little depth the iron disappeared and in its place were found high-grade copper ores.

In the province of Coquimbo and the department of Serena may be mentioned the following mines which are of importance: the Tofo, Cristales, Juan Soldado, and Romeral. Recent developments at the Tofo property have confirmed the views set forth

at the convention at Leeds, namely, that the deposit would become of increased importance as depth is attained. An adit which has opened the deposit at a depth of 180 metres has revealed a large deposit of ore of the same nature as that at the surface. The ore which is at present in sight in this deposit may be safely estimated at 150,000,000 tons. Recently the Bethlehem Steel Company of North America has made a contract with the Sociedad Altos Hornos to buy ore from this property for a term of 15 years with the privilege of extending this time, at the rate of over one million tons of ore per year. This production will in no way interfere with the supply necessary for the Corral company. The work will be conducted under American supervision. The Bethlehem company is going to spend \$8,000,000 in preparation for this work. The plans include the construction of vessels for the special purpose of transporting the ore from Chile to the United States.

The mines of the Cristales district have not been developed to sufficient extent to date to ascertain the exact extent of the orebodies, but there is reason to believe that these orebodies will lead to deposits of importance. It is believed that it will be a comparatively easy matter to transport the minerals of this district to the coast, as a railroad is to be constructed which will supply an outlet. It is also proposed that government engineers will explore this country by means of drills. Various samples, which have been taken, show 60% Fe and some have a high copper content, but the copper is usually independent of the amount of the iron.

Mines of the Juan Soldado District

In former discussions of this district I have presented the information which has been obtained from engineers who have made a special study of the region and have thoroughly prospected it. Some of the prospects, particularly those which have been discovered in the Chacay district and farther south in the Jardin (Quebrada Honda) country, have been proved to be superficial. Trenches, which were cut, went to the barren rock. On the slopes of the mountains in the southern part are to be seen some outcrops from two to three metres wide, which are of interest. A vein one metre wide is also known in the Portezuelo district, but has not been prospected. Many veins are to be seen in a ravine which traverses the district in a north and south direction. The principal vein-system is cut at right angles by another system. Little, however, is known of these deposits. To the south of Romeral, passing down the valley to the Triga district, there are veins which do not outcrop, but which are covered with earthy material. Some of these veins are from 10 to 12 metres wide and appear to constitute good deposits. Between Romeral and Juan Soldado, is the Cepo valley, and the Rincon de las Minas, with numerous outcrops of veins from two to three metres wide and containing a good grade of iron ore with no copper. While the mineral deposits of this region are numerous it would be difficult to work them at a profit. The principal difficulty would be in the mining, which through the nature of the deposits would make exploitation expensive.

The Romeral deposits are situated three kilometres

to the south of Juan Soldado and fifteen kilometres to the east of Punta Teatinos. The superficial deposit of oxidized ore has a general width of 250 metres and a length of about a kilometre. The deposit may be considered as being divided into two parts. In the prospecting work which has been done in the district some good deposits of oxidized ore have been found. It would be well to prospect the ground with drills in order to determine more regarding the extent of these deposits, which are most attractive from the standpoint of quantity and quality of the ore and the ease and economy with which the deposits may be exploited. With the work which has been done to date it may be said that there is at present in sight 15,000,000 tons of good iron ore. The nearest port would be Punta Teatinos; this, however, is an exceedingly poor one and a large amount of work would be necessary to protect it from the south winds. At the present time the only port available is Coquimbo.

Mines of the Department of Ovalle

As one leaves Ovalle in the direction of Punitaqui, at a distance from the city of 15 kilometres, after passing a narrow pass called Cruz Colorada, the sides and tops of the mountains to the west of the wagon road, particularly at a point called Piedra Rodada, show interesting deposits of iron oxides which have a southeast and northwest trend. A railroad has been proposed which will connect Punitaqui with Ovalle and which will pass at the foot of these hills. I have seen large masses of good oxide of iron and also large quantities of mineral, which was not in place, in the district. On the other side of the mountains are to be found the copper mines. To the north are found deposits of iron ore carrying some copper. One of these copper deposits has been prospected to a depth of 15 metres. The principal iron outcrops are to the south of the district.

A shaft was sunk to a depth of 60 metres on the Dorado property and is reported as being in a pure oxide of iron. Mr. Echegarai has made an examination of this deposit and has found some indications of copper and a four-metre vein of good iron ore. With these proofs of a deposit whose apex is high above the plain and which is known to continue in depth, it can be stated that there are many millions of tons of iron ore in it. At the foot of the hill and four kilometres to the south a prospect shaft was sunk four metres and is in good iron oxide. It is planned to continue this shaft to a greater depth. The freight rate from Dorado to Tongoi is about \$1.80 per ton, but this figure could undoubtedly be reduced to less than \$1.50.

At a distance of 33 kilometres from the city of Coquimbo, near Islon, in what is known as a copper country, are to be found good indications of iron. In many deposits the copper is found intermixed with iron and the ore is very silicious. It would be interesting to investigate these deposits at depth. In the same province at a short distance from the railway, which runs from Serena to Vieña, in that locality in which ferro-manganese mines were formerly worked by Joaquín Naranjo, it would be interesting to make a further investigation of the manganese iron deposits.

Department of Atacama

At Yeso, in the department of Atacama, pockets of a black oxide of iron, which do not outcrop at the surface, have been found. These deposits are also to be found in the neighboring hills, but there has not been enough exploration to determine their importance. At Huanteme there are two deposits of iron oxide. The largest has a width of 60 metres and a length of 100; the smaller is 80 metres long and 15 wide. It is probable that these deposits are superficial. The deposits are composed of a dull gray hematite with some magnetite. The Mantos group gives promise of some importance. The last claim, the Beatriz, is 200 metres from the Coquimbana and is 12 kilometres from the mine of that name. This vein has the characteristics of the Coquimbana vein and might be a branch of it. The minerals of this deposit should carry manganese. The vein is two or more kilometres long and five metres wide. The ore is a gray hematite. The Chañar Quemado mines are the most interesting of the department. The principal orebody is 100 metres long and 40 metres wide. The ore is a magnetite. There is a surface deposit of about 40,000 tons of a good oxide of iron. Not enough work has been done on any of these groups to permit an opinion as to their future possibilities. The Santa Lucía deposits lie to the north and show some evidence of mineralization. The principal deposit is 80 metres long and 20 metres wide. The formation is irregular and there is no ore on the surface. The Los Colorados deposits appear to be the most extensive of the entire region.

Speaking of the deposits in general, I do not think they are, for the present, of economic importance because of the grade of the ore and the high cost of transportation. To work the properties, expensive railroad construction and aerial tramways would be necessary. As exceptions, however, might be mentioned the Mantos, Chañar Quemado, and Los Colorados deposits, concerning which it is impossible to give an exact opinion through ignorance as to the quantity and quality of the ore at depth.

Department of Copiapo

In the department of Copiapó iron deposits are in evidence in many localities. The Potrero Seco deposits are 123 kilometres from the port of Caldera. The deposits are irregular and occur at an altitude of about 720 metres above sea-level. The ore appears as outcrops of magnetic oxide of iron, specular hematite, and pyrite. The owners of these properties plan to make a thorough investigation of the deposits. As it is, nothing definite may be said as to their importance.

In the Copiapó district, four kilometres from a little station named Carpa IV, there is a deposit known as the Chamonate. This deposit outcrops with a width of two and a half metres in the form of a dike which has a general north and south trend. Farther to the north there are other outcrops of iron oxide three and a half metres wide, some of which contain manganese.

Seventy-five kilometres from the port of Caldera and four and a half kilometres southeast of Bodegas there is situated a group of iron deposits known as the Bodegas deposits. The outcrops have been very

much decomposed and the mineral occurs as a pure magnetite. In the neighborhood there are copper deposits which have been formed in a carbonate of lime formation. The first of the iron deposits is 60 metres long and 25 wide; the second, which is to the south, is 100 by 50 metres, and a third deposit is of the same size, but broken in formation. These deposits are 280 metres above the valley and it would be possible to transport the ore from the mine by means of an aerial tramway. Other deposits than those mentioned are known in the district. It would be very commendable if the government would undertake drilling operations in one of these localities, such as the Chamonate, in order to ascertain something as to the nature of the deposits at depth and also to learn if water is to be had by sinking.

Chañaral Deposits

The Granate deposits are in the Sierra del Buitre in the Tierra Amarilla district about four and a half kilometres from the railway. One of the veins here is three metres in width and can be traced for a distance of 400 metres. In some parts of the vein there are copper-bearing minerals. In the Sierra de Gallequillos, at a distance of 30 kilometres from Copiapó and at a distance of about 30 kilometres from the bay of Obispo are situated the Portezuelo Negro deposits. Here are known to exist a number of veins of about four metres in width. It would be interesting to prospect this district at depth and ascertain if the many veins united at depth to form one large orebody. The iron occurs as oxide.

The deposits in the department of Chañaral at Varilla are large and important. These orebodies, which have been known for a comparatively short time, are situated at a distance of nine kilometres from Vetado, on the railway from Chañaral to Pueblo Huidido. The station is 13 kilometres from the port of Chañaral. The general strike of the veins of the district is north and south. The outcrop is well pronounced and forms a dike of iron oxide which is about two and a half kilometres long. The width of the dike and its branches vary from 10 to 60 metres. The ore which is on the surface amounts to over 500,000 tons. It would be an easy matter to construct an aerial tramway from these deposits to the station at Vetado, a distance of about nine kilometres, from which the ore could be transported to tidewater at Chañaral. It is possible to transport the ore the entire distance to the port by means of an aerial tramway, which would be about 22 kilometres in length. I have been told by a reputable French hydraulic engineer that it would be easy and cheap to construct a breakwater at the railroad terminal as a protection against the south winds and a pier where it would be possible for large boats to dock. At a distance of 12 kilometres to the west of Pueblo Huidido and at a short distance from the railway, concessions have been asked for the exploitation of iron deposits of an exceedingly good quality.

In the department of Taltal in the province of Antofagasta there are numerous deposits of iron ore. The Cifunchos deposits are situated at a distance of about 12 kilometres from the bay of Cifunchos and at a height of 100 metres above sea-level. Five dis-

tinct veins are to be seen here about 2 metres wide, which extend in a north and south direction for a distance of 2000 metres. Samples which have been taken, indicate a good oxide of iron. To the north of these deposits there is a deposit known as El Vetado, which has a width of from 1½ to 2 metres. Both timber and water are to be had for mines in this district.

The Cachina deposit is situated at a distance of about 7 kilometres to the east of the port of Taltal in a claim known as Miramar at an altitude of 600 metres. The general direction of the strike is northwest and southeast. In an open cut on the claim known as the Salvadora, the vein is about three metres wide. It is not known as yet what the size of this deposit will develop into. The ore is a good grade of red hematite. To the north of this deposit are the Esplotadora, Miramar, and Valparaiso, and to the south the California and Mexico deposits, which have a length of three kilometres. Throughout this entire length, but with interruptions, are to be seen beautiful outcrops of iron oxide. The deposits could be worked by open-cut methods.

The Potrero deposits are of great interest. The Vencedora, Chile, and La Norte Magnética may be of importance. In an open cut in the Alemania claim good iron ore has been exposed. Four metres of good oxide has been opened in the Vencedora claim. There are many faults through the district and the veins which are exposed at the surface may be the branches of a large formation which would be found in depth. Between the larger veins are numerous smaller deposits varying in width from a half to two metres. Sometimes these veins contain copper minerals. The Palermo vein is three metres in width. The strike of the vein is east and west with a dip to the south. Preparations are being made for the prospecting of deposits which are known to exist in the desert to the north and at a little distance from the coast.

There is still much to be learned concerning the iron deposits of Chile, not so much in the south as in the north, but before becoming too much occupied with the deposits that remain to be discovered it would be more profitable to devote more attention to the known deposits and learn something further as to their real value.

The report of the Aramayo Francke Mines, Ltd., operating in Bolivia, shows the following results:

Ore treated, tons	37,660
Black tin output, tons.....	3,694
Black tin sold, tons.....	3,353
Wolfram sold, tons	281
Revenue from metals	\$1 720,000
Dividends paid	432,000
Debentures redeemed	192,000

The properties are at an elevation of 12,000 to 16,000 ft. above sea-level. Facilities for transport are being improved by the completion of a railway line from Uyuni to Atocha. Mining prospects continue to be satisfactory, but labor is troublesome. A tramway, 1800 ft. long, constructed under great difficulties, was finished. The concentration plant will be enlarged, also a plant to treat low-grade silver ores may be erected, while the smelting of bismuth will be continued.

Smelting at Campo Seco, California

By M. W. VON BERNEWITZ

In a hilly and somewhat rough district, although only at an altitude of a trifle over 300 ft. on the Calaveras county side of the Mokelumne river, is the property of the Penn Mining Company. The mine has been opened to a depth of 1400 ft. by the main incline shaft, while below this a winze has been sunk another 300 ft. The country rock may be described generally as a greenstone, and the ore has the following average analysis, gold and silver content being \$1 per ton:

Per cent.		Per cent.	
Silica	23.0	Magnesium	2.0
Lime	1.5	Barium	4.5
Iron	22.0	Copper	5.0
Zinc	6.0	Sulphur	26.0
Aluminum	8.0	Moisture	1.0

This, it will be admitted, looks like a fairly com-

Cars holding 1.3 tons of the bedded ore take it to the 8 McDougall roasting furnaces of the Pacific Foundry type. These are 11½ ft. diameter and have 7 hearths and a drying floor on top. Originally they had only 6 hearths, but the addition of another, and the drying floor, increased each furnace's capacity by about 20%. Rabblers are air cooled by induced draft, and if necessary, air may be forced through the reverse way. The speed is one revolution in 65 seconds, with worm drive, no fuel is used, and the sulphur is reduced from 26 to 8%. Dust losses are 1½% of the crude ore, but a fair quantity of this is saved in the 10 by 10-ft. flue, leading to the 6 by 85-ft. steel stack, which also serves the smelting furnace, being 125 ft. above it. A 15-hp. motor drives the roasting furnaces. The roasted ore is trammed to the charging hoppers over the reverberatory furnace after being weighed.

Anaconda Type Furnace

The reverberatory is of Anaconda type, 20 by 56 ft., of 788 sq. ft. effective hearth area, the roof

THE PENN CO.'S SMELTER AT CAMPO SECO.

plex smelting problem, but as is shown by the following description of the process, the ore is not troublesome. From the main and No. 2 shafts the daily tonnage hoisted is 100 and 40 tons, respectively, that from the latter being higher in silica than from the main part of the mine. All over the surface of the property are tracks laid for the Vulcan steam locomotive, which hauls the ore in Weiner side-dumping 5-ton capacity cars to a 90-ton storage bin. From this the coarse ore is fed to a Gates No. 3 D-type crusher, and the fine passes through a grizzly. All of the crushed material and that from the grizzly is taken by an elevator to a trommel having ⅝-in. holes. The undersize from this goes direct to a conveyor-belt, while the oversize passes through a McFarland 16 by 36-in. set of rolls, then on to the belt with the undersize. An improvement is to be effected here before long in that the roll product will go through a second trommel with ⅝-in. holes, the oversize to be fed to a pair of 12 by 24-in. rolls. Roll shells last three months. All the ore is next conveyed to bedding bins having a total storage of 2100 tons, of which 700 tons constitutes one lot, which is independently sampled. The simple sampling device was described on the 'Concentrates' page of this journal of November 29.

and sides tapering toward the firing end. The roof has a rise of 20 in. at the centre, while the bottom is of fused silica of local quartz, and the sides of silica brick, then magnesite brick on the slag line, the thickness originally being 27 in. The furnace is oil fired, there being three burners of local make, oil being delivered at 80 lb. and steam for atomizing at 100 lb. pressure. Over a period of nine months the oil consumption averaged 43 gal. per ton of ore smelted, this costing \$1.15 per barrel delivered at the works. Charging the furnace with ore is done about six times per 8-hour shift, each charge being 6 tons. During this work, the oil blast is shut off. Ordinary charge holes in the top of a reverberatory burn out in 6 to 8 weeks, but the water-cooled cast iron holes have been in 10 months. Slag is drawn off about every five hours into 25 cars holding 2000 lb. of this material, and the matte is drawn off once or twice daily, the same cars holding 2700 lb. of this product. The cars are taken to the slag or matte dumps as desired, by an electric locomotive. There is a concentration of 10 into 1, and the matte averages 55% copper, an dis crushed, sampled, sacked, and shipped to the American Metal Co. of New York for refining. There is also \$20 per ton in gold and silver in the matte. Copper content of the slag is 0.5%, and

with 45% matte it decreases to 0.4%. It will be seen that with no fluxes and at one operation this complex ore is reduced with no trouble, giving an unusually high-grade matte and low slag.

In the flue from this furnace, which has been in successful operation since February last, is a 250-hp. Stirling waste-heat boiler which generates enough steam to drive a Buckeye 150-hp. cross-compound engine, which is belted to a 120-kw., alternating-current, 440-volt generator, also a small direct-current generator, these supplying the power for the whole plant.

A new reverberatory furnace is being constructed near the one described and will be blown in early next year. It will have a similar roof, but the walls will be of 9-in. brick only, of silica and magnesite as usual, 19 by 60-ft. hearth area, and double ended, the fires to be reversed after every charge. This system is hoped to give good results.

During 1912 the Penn mine produced 51,162 tons of ore yielding 6,058,449 lb. of copper, 112,020 oz. silver, and 2867 oz. gold. A. P. Bussey is superintendent of this interesting property, with D. C. Smith as metallurgist.

Mineral Production in Virginia in 1912

By THOMAS L. WATSON

The value of the mineral production of the Virginia mines and quarries in 1912, as reported by the Virginia Geological Survey in coöperation with the U. S. Geological Survey, is shown in the accompanying table, together with the corresponding information for 1911. The total value of the production of minerals in the state in 1912 amounted to \$21,276,157, as compared with \$19,314,567 in 1911, an increase of \$1,961,590, or slightly over 9 per cent.

Coal is much the most valuable product from an industrial standpoint. The quantity and value of coal mined in Virginia in 1912 exceeded by nearly a million tons in quantity and more than \$1,250,000 in value the production of any previous year. The figures were 7,846,638 short tons, valued at \$7,518,576, an increase of 981,971 short tons in quantity and \$1,263,772 in value over 1911. The coal areas of the state which have produced or are producing are: (1) the Richmond coal basin in the eastern border of the Piedmont Plateau, and the only area of free burning coal in the Eastern part of the United States that is immediately adjacent to tide-water; and (2) the Appalachian region west of the Blue Ridge, which comprises a number of separate areas extending entirely across the state from Frederick City on the north to the Tennessee boundary on the south. New developments are in progress which will lead to an advance in coal-mining in Virginia in the near future.

Clay and clay products, derived from Tidewater, Virginia, showed a substantial growth in 1912, increasing from \$1,743,007 in 1911 to \$1,884,743 in 1912. Improved conditions in road making and the building trades in general brought about an increased production of quarry materials, such as granite, limestone, slate, etc., which amounted to \$1,072,382 in 1912, as against \$1,010,606 in 1911.

Many other products showed a substantial increase in 1912 over 1911, chief among which are mineral waters, talc, and soapstone, pyrite, millstones, etc. A noticeable decrease was shown in iron ores, and to a less extent in some of the lesser products, which is considered to be temporary only.

VIRGINIA MINERAL OUTPUT IN 1911 AND 1912¹

	1911.	1912.	Increase or decrease.
Clay products	\$ 1,743,007	\$ 1,884,743	+\$ 141,736
Coal	6,254,804	7,518,576	+ 1,263,772
Coke	1,615,609	1,815,975	+ 200,366
Granite	420,611	470,657	+ 50,046
Iron ores	1,146,188	903,130	— 243,058
Iron, pig	3,898,285	4,364,708	+ 466,423
Lime	483,016	488,628	+ 5,612
Limestone	369,872	403,063	+ 33,191
Manganese ores	24,546	14,881	— 9,665
Metals (gold, silver, copper, lead, and zinc)	169,394	74,855	— 94,539
Millstones	17,635	25,866	+ 8,231
Mineral waters	298,701	349,255	+ 50,554
Pyrite	558,494	621,219	+ 62,725
Sandstone	31,315	4,020	— 27,295
Sand and gravel	204,170	291,773	+ 87,603
Slate	188,808	195,392	+ 6,584
Talc and soapstone ...	660,926	576,473	— 84,453
*Other products	1,229,186	1,272,943	+ 43,757
Totals	\$19,314,567	\$21,276,157	\$1,961,590

*Includes asbestos, barytes, cement (portland), feldspar, ferro-alloys, gypsum, infusorial earth, manganese ore, mica, ochre, and salt in 1911, and barytes, cement (portland), feldspar, ferro-alloys, fuel briquettes, gems and precious stones, gypsum, infusorial earth, manganese ore, metallic paint, ochre, rutile, and salt in 1912.

¹These figures are published in more elaborate form in Bulletin VIII of the Virginia Geological Survey.

An Old Arrastre

The accompanying half-tone shows one of these old machines at Blewett, Chelan county, Washington. It is especially interesting, as it was hewn out of the solid bedrock of the creek. The rock is dark

ARRASTRE CUT OUT OF SERPENTINE.

green and compact and composed principally of hornblende, with white streaks of quartz and feldspar and is finely polished. It was hewn by a half-breed Indian named Culver about twenty-five years ago, and it is said that he extracted a small fortune with it from free-milling surface ore found in this district.

Taiwan, in the first six months of 1913, yielded: gold, \$400,485; copper, \$257,788; coal, \$251,094; sulphur, \$14,053; silver, \$17,222; petroleum, \$24,534.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual complacency. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—The above scholarly paper will doubtless be criticized at length by the distinguished geologists and engineers mentioned in Mr. Rickard's introduction, but the matter discussed is of great interest to all who take more than a mere monetary interest in their profession. Besides, we must not lose sight of the fact that as, judging from the introduction and the undoubted high status of the author, this paper is likely to settle definitely the dispute about the origin of the gold in the Rand banket. There is danger that in the future the views of the author are liable to be accepted as authoritative and final; therefore, as I believe that I have evidence contravening some of the statements about pyritic pebbles in general, I offer it forthwith, notwithstanding that we in England have so far received only the first installment of the paper.

In December 1911, while exploring and examining some mining permits in a remote part of the Natal district on the west coast of Sumatra, I came across some conglomerate of the Cretaceous period on which I found gold. I may add, by the way, that so far as my observations indicated, there was no gold actually in the conglomerate, or, at any rate, none similar to the gold that was receiving my attention at the time.

During the course of my work, as recorded in my diary, I found in the conglomerate a piece of vein-quartz, banded black and white, weighing about a kilogram. This, on crushing and panning, yielded pyrite, but no gold. I believe, and hope, that I saved a piece of this vein-quartz, but if so it is stored with goods where I cannot get at it at present. However, I have at hand some of the pyrite as washed out, and have forwarded it to C. B. Horwood in case it may be of interest. I, too, have seen mine-water and other surface-water heavily charged with iron sulphate owing to the decomposition of the pyrite, but surely this is no argument against the possibility of pyritic 'pebbles' occurring in a conglomerate of the pre-Cambrian period, such as the Rand banket, because many of us suppose, as we think, reasonably, that the atmosphere of pre-Cambrian days differed greatly in composition from that of the present (or Rio Tinto) day; in fact, we believe that in composition it approached very nearly to the original atmosphere, that is, carbonic acid, nitrogen, and aqueous vapor.

My pebble from a Cretaceous conglomerate was rather large. Still, from a general recollection of the surroundings and of the appearance of the pebble, I can recall no reason why smaller pyritic pebbles should not have occurred among other smaller pebbles. While in an inert (so far as oxi-

dation) atmosphere, such as I assume that of the pre-Cambrian period to have been, I see no reason why, provided they escaped destruction by attrition, even single grains of pyrite should not survive. Notwithstanding my remarks, which must be distinctly understood to combat only the idea concerning the impossibility of pyrite pebbles occurring in a pre-Cambrian conglomerate, I look forward to the details of Mr. Horwood's proof that the pyrite forming the Rand pebbles is secondary and was introduced long after the formation of the banket. I hope, too, that in one of the future installments we may be given an analysis of the Crown Reef dike where it is most and least altered, or an analysis of at least one of the typical dikes that occur so frequently in the mines of the Rand. In the latter remark I know that I am anticipating, but it so happens that I was searching for information on a similar point only the day before I received my copy of the *Mining and Scientific Press*.

STEPHEN J. LETT.

London, October 26.

The Editor:

Sir—In the installment of 'The Rand Banket' by C. B. Horwood, Part III (*Mining and Scientific Press*, November 1, 1913), the author displays a singular misunderstanding of Van Hise's rule for the change in volume accompanying metasomatic replacement, which he dismisses (page 676) in the following terms: "Moreover, in this example the two parts of his formula contradict one another; as according to the first part of it the volume occupied by the pyrite should be greater than that previously occupied by the replaced substance; and the second portion of his supposition requires that the pyrite should fill less space than was filled by the material replaced. Thus no great importance need be attached to his statement as a whole."

Van Hise's rule as stated in his 'Treatise on Metamorphism,' page 209, is as follows: "The volume of the original compound is to the volume of the compound produced directly as their molecular weights and indirectly as their specific gravities." Herein the author reads two separate and mutually contradictory principles instead of, as is obvious, a coherent formula expressed in words rather than symbols. Applied to the phenomenon under consideration, that is, the metasomatic substitution of pyrite for a quartz pebble in the conglomerate, it is only necessary to introduce the corresponding quantities, letting V_1 represent the volume of the original quartz and V_2 the volume of the substituted mineral, pyrite, thus:

$$\begin{array}{rcl} & 60.4 & 120.0 \\ V_1 : V_2 = & : & \\ & 5.0 & 2.7 \\ & = 302.0 & : 324.0 \\ & = 1.0 & : 1.07 \end{array}$$

It follows therefore according to Van Hise that pyrite, completely replacing a quartz pebble, would occupy a volume 7% greater than the latter. The accuracy of this figure, however, is conditioned by the exactitude of the specific gravities, respectively 5 and 2.7, stated by the author. As an example, if the specific gravity of the pyrite were as high as

5.2 and that of the quartz 2.6, it would be found that, instead of an increased volume, the pyrite would occupy a slightly smaller space (a fraction of 1%) than the replaced silica, which is more in accord with the author's observations.

HENRY H. KNOX.

New York, November 10.

Are there Jobs Enough to go Around?

The Editor:

Sir—On page 11 of the pamphlet issued by the sixteenth session of the American Mining Congress, I note the following paragraph of unknown authorship: "With the growth of the mining industry comes an increased demand for men with the technical training which is necessary to this highly specialized business. The growth of mining schools under state control furnishes indisputable evidence of this demand. Agricultural schools fostered by the federal government have been fully justified by results. Mining needs *more* greatly and is equally entitled to federal aid in the making of experts capable of dealing with its many times more difficult scientific problems."

I think these statements are misleading to the young and innocent: They do not express the true idea. There has been an increased demand numerically for technically trained men, but the supply has increased faster than the demand, so that the ratio of demand to supply is smaller today than it ever has been. The price of technical service is cheaper than ever before, remembering that this question is not concerned with the exceptionally talented man, but with the average intelligent technical graduate.

The ideas quoted above have been responsible for the flooding of the field with mining engineers. Literature of this kind has done the profession a great deal of harm, though it has benefited the industry by giving it greater competition among engineers and therefore cheaper service.

The growth of mining schools cited above as an example of this indisputable evidence, etc., has not been a healthy one. Probably 50 per cent of the graduates of these schools are out of a job. A great many have been crowded into some strictly commercial field which they entered as a last resource.

An advertisement in one of our journals for a technical man or a perusal of the application files of a big corporation will soon show the surprising number of men who are on the market, and who through the severe competition are compelled to take anything to keep going. Technical men had better opportunities twenty years ago than they have today.

The mining industry has benefited by getting technical men to do the work that was formerly done by untrained men and not paying any more for the improved service. The industry is getting better surveys, ore samples, assays, maps, models, reports, etc., than formerly, and is actually paying less for it.

Is it proper to deceive our high-school boys by telling them that the future mining industry will

give them more openings, or a wider market for their services? Why not tell them the truth and say that there are more applicants for every technical position in the industry than there is in any other industry, and that the profession is as overcrowded as that of law or medicine?

There is always room at the top for the right men, but let there be no delusions as to the severity of competition in getting there, nor as to the future expansions of the mining engineer's field. There is already too much ignorance on the part of technical students concerning what is required of them in the profession. There are too many men in the field who by constitution are ill adapted to the all-round requirements of the profession.

Some of our universities are recognizing the conditions and are trying to raise the standard of scholarship in their graduates by making their course post-graduate. This again misleads the student into believing that scholarship is the thing, whereas the solution lies in wider experience with severe practical work of all kinds under actual money-making conditions. The severe practical work would act like a cathartic on the large classes that are drawing sheepskins every year. The process of elimination had better go on at that stage than afterward, because it is going to come sooner or later. A whole year's practical work between sophomore and junior years for one of the big operating companies for the usual wages, bunkhouses, and grub would change the ambitions of many who never realized that these conditions are any item in the business. It would be an act of charity to many who learn it only in time to become salesmen for a machinery or powder house. It would also make the quotation of engineer's degrees go up some in the labor market, and incidentally give our college instructors the rare treat of talking to men who had learned what a college could do for a man and what it could not do.

To come back to our article, let us recognize that new mining engineers are entering a crowded profession that has fewer openings now, relatively speaking, than it used to have; that there is no indication of a runaway market in sight in the future; and that a high standing in scholarship is no measure of their character, personality, tact, originality, courage, and nerve, and a whole host of qualifications which are in reality the determining factors of success.

F. SOMMER SCHMIDT.

Salt Lake City, October 28.

Grinding-Pan Practice

The Editor:

Sir—The article on 'Grinding Pans at Kalgoorlie,' by M. W. von Bernewitz, in the *Mining and Scientific Press* of May 17, and the subsequent discussion, was particularly interesting to me, because at the mill with which I am connected, grinding pans are run as slimers in closed circuit with mechanical classifiers, and are giving excellent results.

According to the description of pan practice at Kalgoorlie, the discharge lip of the pan is used as a return classifier for sand which requires further comminution. This should give similar results as

arranging the pan in closed circuit with a separate classifier. But if in the latter system an efficient classifier is used, it has the advantage of exclusively returning to the pan the material that needs finer grinding. On the contrary, the discharge-lip classifier, working under free settling conditions, must give an underflow with considerable slime, thereby diminishing the capacity of the pan. The high duty of 30 tons per 24 hours ground through 200 mesh by a 5-ft. pan, obtained at our mill, may be partly

DIAGRAM SHOWING ASSUMED LEVEL OF PULP IN GRINDING PAN.

ascribed to the fact that the classifiers keep all slime out of the feed. The capacity is also favorably influenced by directly discharging the pulp, after it has once passed underneath the muller, without returning it to the centre of the pan by deflectors. Thus the pulp, which is fed at the centre, comes between shoes and dies entirely free from slime. An advantage of having the classification done by the slotted-discharge lip is that an elevator or pump is not needed, which is indispensable for returning the discharge pulp of the pan if a separate classifier is used.

Mr. von Bernewitz does not explain how the underflow of the discharge lip is again fed to the pan. The pulp takes a paraboloidal shape with the apex in the centre of the pan; the elevation of the pulp at the periphery above the level in the centre is proportional to the number of revolutions of the muller and amounts to at least 12 in. when the muller revolves at 50 r.p.m., or more. Therefore it would seem feasible to convey the returning pulp to the centre of the pan by a pipe passing through the body of the pan, as shown in the accompanying sketch. I do not know if this is the way in which the return of coarse pulp is effected at Kalgoorlie, and should feel obliged to Mr. von Bernewitz if he would elucidate this point.

M. G. F. SÖHNLEIN.

Ingenio de Machacamarca, Bolivia,

September 17.

The Editor:

Sir—I am pleased to know that my notes on this subject have been well received in far-off Bolivia,

and think that Mr. Söhnlein's pan results are interesting. As I said in my reply to Mr. Randall in the *Mining and Scientific Press* of November 8, a properly devised overflow lip classifies to a large extent, but a separate classifier in closed circuit with a pan would probably do better work. The coarse pulp is not returned to the pan as in Mr. Söhnlein's sketch, and at 50 r.p.m. the pulp does not assume the shape shown, but keeps level. Referring to my original article of May 17, 1913, on page 735 is a description of the flow of pulp in a pan. The discharge lip of a 5-ft. pan is about 18 in. long, 24 in. wide, and the same depth as the pan, being bolted on to it. About 2 in. from the top of the pan, on the lip side, are a number of 1-in. holes made during casting the pan, through which the pulp flows to

FRONT AND SIDE VIEW OF DISCHARGE LIP.

the lip, and on the lip side of the pan, close to the bottom, is a slot about $11\frac{1}{4}$ by 6 in., through which the coarse sand is drawn into the pan from the lip by the suction of the revolving muller. A lip holds about 20 gal. of pulp, and is always full, as is true of the pan. On the outside of the lip is a launder to carry off the slime overflowing. This is so in a sliming pan, but in one used for stage crushing, such as the Freeman or Cobbe, the pulp assumes a shape somewhat similar to that in Mr. Söhnlein's sketch, as the overflow devices are quite different.

M. W. VON BERNEWITZ.

San Francisco, November 1.

The following rules relative to underground timbering are selected from certain regulations used by iron-ore mining companies in the Lake Superior district: Timber must not be hoisted or lowered through a shaft, compartment, or raise that contains a ladder. In drifts and openings, timbering shall follow as close to the breast as is practicable; in soft ground sets must be placed as soon as there is room, and the roof must be secured by poles resting on the eap and set into holes at the top of the breast, these poles to remain as lagging; loose dirt on back and sides must be carefully trimmed. When timbering is being done on a stope or a raise, special care must be given to platforms and staging; stage poles shall be put about $21\frac{1}{2}$ ft. apart when raising. No spikes or nails shall project from timbers or boards placed where the nails may be stepped on or may tear flesh.

Coal exports from Newcastle, New South Wales, during the first nine months of 1913 amounted to 3,786,432 tons, valued at \$9,645,727. This fuel is sent to other Australian states, New Zealand, islands in the Pacific ocean, and the west coast of North and South America.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Filling stopes with sand at the Simmer & Jack mines, on the Rand, costs 6.8c. per ton lowered, on the surface, and 13.2c. underground, a total of 20c. per ton sent below.

Deister No. 3 slime tables should be run forward, at a speed of 265 to 300 r.p.m., with an average stroke of $\frac{7}{16}$ in. On light copper sulphide ores a speed of 265, and for zinc-lead separations a speed of 300 r.p.m. will give good results.

Shaft sinking at the Nevada Wonder mine during the past fiscal year averaged \$34.26 per foot. This included the cost of enlarging and fitting up the 700-ft. station for an electric sinking hoist, and cutting stations on the 800, 900, and 1000-ft. levels.

Announcement has been made at Washington that hereafter certificates will be issued upon final proof in the case of application for patent on mineral claims. This will relieve the applicant from doing assessment work during the time that the Field Division is examining the ground.

Free determination of mineral specimens is made by many state's institutions. Samples addressed to the California State Mineralogist, Ferry building, San Francisco, will receive attention. There must not be more than three sent at one time, and they must come from places within this state only.

Prospecting gravel for future dredging operations is done by drilling or sinking small pits or shafts. From the latter, the whole of the gravel removed is washed and averages calculated. This is a good system when the gravel is dry; but where there is a large quantity of water to contend with in the pit, and pumps must be used, results are very apt to be misleading. In this case the drill is more suitable, although even then great care must be taken, and the personal element of the man in charge has to be considered.

Means of locomotion by mining engineers, geologists, and others in the field is of importance. Considerable time is generally lost in getting from camp or hotel to the point where work begins, in returning at night, and in moving headquarters. It is important that the geologist should travel quickly and arrive at his work fresh and full of energy, according to Joseph Barrell. This is the first point in geologic methods on which the efficiency engineer would probably put his finger. The motorcycle could without doubt be made of large use in this respect. With it the worker could reach distances of twenty miles in the same time he would walk three. From one base 1600 square miles could be reached with the same facility as 100 square miles by walking.

Disposal of residue at Kalgoorlie is done by the following methods: tramping with horses on the Associated Northern; cars drawn by electric loco-

motives at the Ivanhoe and Perseverance; belt-conveyors at the Horse-Shoe; and sluicing or pumping at the Associated, Boulder, Kalgurli, Lake View, Oroya-Links, and South Kalgurli; belt-conveyors for this purpose have been practically discarded in favor of the pumping system. The old dumps were becoming a nuisance in many ways, and are slowly disappearing by being re-treated or used for underground filling. For the pumping system the government sells water at 36c. per 1000 gal., but none from the ponds can be returned. At the Boulder, Lake View, and Oroya-Links vacuum plants, the residue drops into mixers or very strong agitators, where it is mixed with water and pumped away. At the Kalgurli the residue is taken from the presses to a mixer

A SLIME DUMP AT KALGOORLIE FORMED BY PUMPING.

by cars. At the Associated and Lake View the press residue drops onto belts and is discharged into a vortex mixer, and pumped away to ponds on their own leases. At the South Kalgurli, the press residue drops to sloping floors and slips down into a mixer, then to two agitators large enough to hold the residue from an eight-hour mill run, from which it is pumped away from the mine, twice a day, the pipe is afterward washed with clean water. The vortex mixers are driven at 150 r.p.m. by gearing or quarter-turn belts, the latter being a good method and eliminating all noise. At the Associated, the cheap water is used in addition to all the salt water from the mine, change-room discharge, boiler blow-off, and general catchment. A motor-driven geared mixer uses 6 hp. The amount of water used varies, but in addition to 20% moisture left in the press-cakes, there is required about 140 gal. per short ton. In vacuum plants a smaller amount is required. Pumps used have two or three slow-speed plungers, packed with greasy hemp or a graphite composition, and also clean-water jets to prevent their cutting out. It was noticed that when this pumping method was first used, the pipes gradually filled up. The practice is now to make sure that the pipe is discharging at full capacity all the time, and when pumping is finished the pipes are washed out with clean water, thus preventing their choking. In laying a pipe-line, care should be exercised that there be no depressions in the line where settlement will take place. Costs are as follows: tramping by horses, 10c.; by belt-conveyors, 10c.; by electric locomotives, power at 5c. per kilowatt, 12c.; and by sluicing or pumping, 7 to 12c. per ton of dry ore treated. The accompanying half-tone shows how slime dumps or ponds are formed on level ground, the mill residue being pumped to them and then gradually built up of this material.

TORONTO, CANADA

CORALT ORES AGAIN BEING SHIPPED IN LARGE TONNAGES.—LA ROSE AND SENECA SUPERIOR.—INVESTIGATIONS INTO COBALT ORES.—DOME LAKE, TECK-HUGHES, AND JUPITER.—OIL IN ALBERTA.

The difficulty which was experienced some weeks ago in marketing Cobalt ores appears to have been satisfactorily overcome, as the weekly shipments have been heavy of late. The statement of the La Rose Consolidated for October shows an output of 203,454 oz. silver and profits of \$67,927. The surplus on hand was \$1,709,579. The extension of the Seneca Superior vein on the Gould Consolidated property adjoining, has pinched out after being followed for 30 ft. The Seneca Superior has cut its main vein on the 100-ft. level, where it contains about 6 in. of 1000-oz. ore. It is wider, but not so rich as on the lower levels. The Mines Branch of the Canadian Department of Mines is promoting an investigation which promises to have important results for the Cobalt silver industry. Hitherto the shippers of Cobalt ore have had little advantage from the cobalt content of their consignments for which the smelters, as a rule, make no returns, so the Mines Branch has engaged H. T. Kalmus, of Boston, to conduct a series of experiments at Queen's University, Kingston, to devise a process for the economic reduction of cobalt from the ore, and the production of alloys from the metal. In a preliminary report, Mr. Kalmus states that so far he has met with encouraging results, and ascertained that the method of preparation by direct reduction with carbon can be done commercially at low cost. The pure carbon produced, he claims, has a tensile and compressive strength higher than any of the ordinary pure metals, and can readily be electroplated. As regards alloys with which he has experimented, he finds them considerably harder than the best tool steel, with both elastic limit and tensile strength as high as the standard specifications for structural nickel steel. The specific object of his researches is to produce an alloy combining lightness and strength suitable for the manufacture of automobile parts. It is estimated that, since Cobalt began producing, about 7000 tons of cobalt has been shipped in silver ores, for which mine owners have only received \$566,000, in place of \$10,000,000 which this content should have been worth to them.

The control of the Dome Lake has passed to interests associated with the Temiskaming & Hudson Bay of Cobalt. The shareholders on November 27 authorized the sale of 205,000 treasury shares at 17½c. per share to Thomas Reid. The Company will realize about \$35,000, which will enable it to pay off liabilities and proceed with development. The Teck-Hughes, of Kirkland Lake, has also changed owners, Harry Ceell, representing an English syndicate, having purchased from the Great Northern a three-fourths interest. A large outlay will be made for development. The shareholders of the Jupiter, at a meeting held in Montreal on November 24, have authorized the issue of \$50,000 in 6% bonds, running for eight months, to be offered to shareholders pro rata at 80 per cent.

The oil discovery at Black Diamond, near Okotoks, Alberta, which has been the cause of the flotation of a number of companies, despite the warning issued by the Calgary Board of Trade, which pointed out that the value of the deposit was exaggerated, has been followed by another oil boom near Athabasca Landing in the same province. A reported find in that locality resulted in a rush to take up claims, and four whole townships comprising over 70,000 acres were taken up in about two hours. No definite information as to the latter discovery is available, but the first is verified by the Geological Survey as far as it goes. The sample of oil forwarded was pronounced to be a 'white oil,' extremely light for a natural oil, and consisting largely of gasoline. Such oil is rarely found in quantity, but the officials of the Survey think it may be an important indication of petroleum in large quantities in the vicinity.

NEW YORK

FLOTATION LITIGATION AND POSSIBLE RESULTS.—OPERATIONS AT THE CHUQUICAMATA AND BRADEN MINES IN CHILE.—CALUMET & ARIZONA AND SHANNON.

Interest is keen here in the progress of the infringement suit of the Minerals Separation, Ltd., against the Butte & Superior. The first suit was against James W. Hyde, who claimed improvements on the Froment process then in use in the Butte & Superior mill, and was concluded by a sweeping decision for the plaintiff. As a matter of fact, the defense of the suit was decidedly weak, and the Butte & Superior can hardly have held a very strong hope that it could make good its contention that the Minerals Separation patent was anticipated by the Froment patent, because if Froment had tried to operate his process he would have found it necessary to modify it until it would have been substantially that of the Minerals Separation. As Mr. Hyde is no longer in the employ of the Butte & Superior, it was necessary to bring a second suit against that Company. To this suit the defense was made that Mr. Hyde was not the agent of the Butte & Superior and that the process now in use there was devised by F. G. Janney. The judge held that the Butte & Superior was now infringing the patent of the Minerals Separation, but refused to grant an injunction against the operation of the plant on the ground that 900 men would thereby be thrown out of employment, without sufficient compensating advantage to the plaintiff. The Butte & Superior was therefore directed to file a bond for \$75,000 and to report its output to the court each month. It may be expected that the suit will be fought to the uttermost limit of legal ingenuity, for the process in suit is practically identical with that of the Minerals Separation, and if the latter loses this suit all hopes of profit in this country will be practically swept away. The stake for the Butte & Superior is also large, since the claim is for \$3,000,000 damages and \$1.25 per ton royalty for subsequent use of the process. The main stake is even larger than this, for the dominant interests in the Butte & Superior are the chief factors in Utah Copper, Ray, Chino, and Nevada Consolidated, which have a combined yearly output of 400,000,000 lb. of copper and which are now only saving about 66% of the copper in their ores. If by any means they can obtain the right to use a flotation process on these without the payment of a royalty, the gain will be tremendous, and the cost of fighting the suit to a finish is a 'good spec.' The royalty demanded is, of course, high, being on the basis of the claim allowed by law in case of willful infringement, and probably also to allow latitude for compromise in a final settlement. It is understood that the royalty to be paid by the Elm Orlu is about 25c. per ton, and that some copper companies have concluded contracts at about half that figure, since the royalty is based on the amount of mineral recovered rather than on the tonnage milled. The Inspiration expects to have its mill in operation in a few weeks, and the 250-ton plant of the Consolidated Arizona should be ready soon after the first of the year.

The ore reserves in the new Guggenheim property in Chile, at Chuquicamata, were already so large that the recent announcement that 100,000,000 tons have been added to them does not create even a ripple. Even the 200,000,000 tons of 2.5% ore now do not exhaust the possibilities of the property, for the outer boundaries of the orebodies have not been found in many directions. The first 10,000-ton unit of the leaching plant is planned and construction is about to begin. Word comes also that the reserves at Braden have been largely increased through the connection of the Fortuna and Teniente adits. S. S. Sorensen is now in charge and Pope Yeatman is also at the property, where he intends to stay until it is put in shape. The mill will be doubled in size, increasing it to 6000 tons capacity, and it is stated that the increase will only cost \$500,000, as compared with the \$2,500,000 spent on the first mill. Nothing recent has been given out in regard to the leaching plant at the Braden, as the attention of everyone there seems to have been concentrated on the more insistent difficulties.

Speaking of leaching, 'everybody's doin' it,' and the

Wagner Azurite Copper Co., at Luning, Arizona, has contracted for a 100-ton plant to be erected by the people who built the Butte & Duluth plant. The Kelvin-Sultana is also considering a 60-ton leaching plant, and nearly everyone is looking into the matter. The Calumet & Arizona smelter made an output of 4,500,000 lb. of copper in October, an increase of 500,000 lb. over the preceding month. The Shannon has made its quarterly report, showing an output of 3,362,157 lb. copper at an average cost for the quarter of 13.83c., the yield per ton being 44 lb. copper from the Shannon ore. The Shannon is one of the properties which operates at a cost so close to the selling price of copper that a decline in the price of the metal, such as the present market is showing, puts it into a bad condition.

An amusing rumor is in circulation that the Inspiration

over 205,000 shares of the Dome Lake at 17½c. per share. This, added to the 200,000 shares acquired a short while since, gives it control of the Dome Lake. This property covers 120 acres in Tisdale township and has a 10-stamp mill erected. Recently about 1000 tons of \$9 ore per month has been milled. The 'upset' price of the stock is a sad decline from last March, when it reached \$3 per share. M. A. Teague found the property in 1911, but it proved a failure, and the stock in the \$2,500,000 Company declined to 6c. per share. Early this year the capitalization was cut to \$500,000, and this furnished the ammunition for a new market campaign which carried it back to \$3. Under the new management the hopes for eventual success are much brighter.

Charles Butters has obtained patent No. 1,078,994, covering a modified filter now in use at the Tonopah Belmont

GENERAL VIEW OF MOLINO, CHILE, SHOWING BRADEN CONCENTRATORS.

is about to take over the Mines Company of America, based on the fact that Charles Biesel and W. B. Thompson had a conference at El Paso recently. As a matter of fact, W. B. Thompson and W. H. Aldridge are already the chief moving spirits in the Mines Company, as John Lambert, W. E. Ries, and A. T. Black, who control the Company are not gold and silver mining men, and are doubtless glad to have the assistance of such competent *confreres*. In speaking of copper companies, it is interesting to notice that the convertible bond issue of the Chino has nearly all been converted, that Company now only having about \$250,000 in bonds outstanding. The Nevada Consolidated only has \$500 of its bonds still out. The Nevada Consolidated declared an extra dividend of 50c. per share, payable December 31, in addition to its regular quarterly dividend. This was a great surprise, as it had been said that the Nevada Consolidated would proceed to build up a big surplus. As a matter of fact, this payment will make the year's dividends exceed earnings by nearly \$1,300,000 and correspondingly reduce the present surplus.

The outlook for the Ohio Copper Co. is considerably improved by the appointment of George F. Waddell as mill superintendent. Mr. Waddell is an old Butte man who has been mill superintendent for the Nevada Consolidated for several years, and his extended experience should benefit Ohio.

The Temiskaming & Hudson Bay Mining Co. has taken

mill and designed to overcome claims of infringement on the part of the Moore Filter Company.

LONDON

MOVING PICTURES AND MINES.—TOMBOY SHOWS GOOD RESULTS.
—GENERAL PETROLEUM FINANCED.—NATOMAS CONSOLIDATED NEEDS NEW CAPITAL.

The cinematograph has recently been used in London on several occasions for enlightening shareholders and the public as to the nature of mining operations. For instance, at the meeting of bondholders in the Natomas Consolidated an exhibition was given of the work of the gold-dredges. One of the London firms of film-makers has been taking views of Cornish mines, at the suggestion of Oliver Wethered, a London promoter, who has been instrumental in introducing outside capital into Cornwall. Nearly twenty years ago he found the greater part of the new funds required for rehabilitating Dolcoath after the severe effects of the great slump in the price of tin. One of his latest ventures is the reclamation of tin sand from Gwithian beach at the mouth of the Red river. At Mr. Wethered's invitation, a large audience assembled at one of the West End picture palaces the other morning. The series of pictures at Dolcoath were excellent, and included pay-day, ambulance practice, rock-drilling, the air-compressor, revolving roasting-furnace, dispatch of concentrate in bags

to the smelter, etc. Views were also given of the Geevor mine, and of Gwithian sands. Hitherto promoters and directors have only shown plans and specimens of ore, neither of which convey much idea to the layman shareholder. The pictures should help in reviving interest in mining among the public. The technical men present at the demonstration were pleasurably affected by the show.

The last year or two has been a dull time in mining in all parts of the world, and the press and the societies are discussing the reason. By many it is said that the public stand aside because they do not get a chance against the director and other inside speculators. That this is often, and even usually, the case, is only too true. For that reason, when we come across a company run for the benefit of the shareholders, we feel a gladness of heart, and its reports and the chairman's speeches act as an inspiring tonic. Such a company is the Tomboy, which owns property in Savage basin, Colorado. This is one of the Exploration Company's group. Ever since R. T. Bayliss assumed control, the Exploration Company has been noted for its thought of the shareholder and its contempt for private use of inside information. The Tomboy company was formed in 1899, and two years later, on it becoming apparent that the deposit did not persist in depth, John Herron, the manager, acquired the adjoining Argentine property. It was only a prospect at that time, and the price in cash was insignificant, but those who knew the geology of the ore deposits of the district were confident that the acquisition of the property was an excellent stroke of business. This view has been upheld by subsequent events, for dividends approximating £450,000 have been distributed on the output of a property that only cost about £15,000. Two years ago the Argentine orebody began to show less promising results of development, so again the Company sought for other property in the neighborhood. Eventually the Montana group of claims, forming the southern portion of the Revenue Tunnel company's property, was acquired for £80,000 cash. This sum was provided partly out of reserve and partly from profits. The ore extracted has already nearly recouped the cost. Development during the past year was satisfactory in spite of one or two disappointments owing to the veins being not as wide as expected. The reserve on June 30 was approximately 160,000 tons, averaging over 9 dwt. gold and 4 oz. silver. In the Argentine the reserve is 260,000 tons. Little exploration has been done at the latter lately, as it was deemed better to push the development at the Montana property. A glance through the quotations of Tomboy shares shows their steadiness at an uninflated level, contrasting in a wholesome manner with the absurd quotations and violent fluctuations characteristic of the Rhodesian market. The metallurgical problem at the Tomboy is of unusual interest, owing to the nature of the concentrate obtained and the various base metals in the ore. Gelasio Caetani and W. K. Betty have done excellent work, in consulting capacity, with regard to the recovery of the metals, in conjunction with D. A. Herron, the present manager. No doubt an exhaustive article on the subject will be published ere long, when the present modifications are completed.

Two important Californian enterprises are about to be re-organized, with a view to raising further capital in London. I refer to the Natomas Consolidated and the General Petroleum, both of which are American companies, but are now to be registered under English law. Among the sponsors for the General Petroleum are Andrew Weil, Arthur M. Grenfell, and H. C. Hoover; this is a strong combination. The Company is in an excellent position, and presents a contrast to the Natomas Consolidated. The latter is in a bad way, owing to serious miscalculations with regard to both finance and engineering. Not only do the bondholders suffer, but also E. J. de Sabla, the promoter. The engineering data and the financial requirements were stated plainly at the time of flotation, and it is no secret that Mr. de Sabla asked for \$2,000,000 more than the estimate of working capital put forward, namely, \$10,000,000 instead of \$8,000,000. The estimate of yield and cost of plant, made by C. M. Rolker, has proved to be a long way out. During three years of dredging, the

yield was \$3,000,000, as compared with \$5,000,000 estimated, and his estimate of cost of plant was too low by \$800,000. In view of these figures, Mr. Rolker's estimate of the gold content to four places of decimals of a cent provokes a cynical smile. It is practically certain that the new capital required will be forthcoming in London, and, if so, it will have an excellent effect in strengthening the financial position in California, recently shocked by the failure of the F. M. Smith enterprises.

JOHANNESBURG, TRANSVAAL

DEEP MINING ON THE RAND AND THE JUPITER PROPERTY.

The prospects of deep mining on the Rand have not been improved by the recent closing down of the Jupiter mine. Of the three deepest mines on the Rand, namely, the Cinderella Deep, Simmer Deep, and Jupiter, the last has led the way, and the lowest point reached is over 5000 ft. below the shaft collar. Of the other deep mines, it has also been deemed advisable to suspend operations at the Cinderella Deep, while at the Simmer Deep, despite the fact that very large sums of money have been spent in its equipment, the results obtained are far from satisfactory.

It will be remembered that six months ago, at the last meeting of the shareholders of the Jupiter mine, the situation of the property was carefully explained, and it was announced that the board of directors was considering the advisability of increasing the capacity of the ore-reduction plant from 40,000 to 60,000 tons per month, and so enable the mine to earn increased profits with ore of a mine grade of \$4.10 per ton. This scheme was decided upon, and every arrangement made necessary for the successful carrying out of the enlarged scale of operations, even to the raising of the necessary capital, but the strike disturbances in July, and the consequent exodus of native labor, made it necessary that the board of directors should reconsider the position. Without an adequate supply of native labor, some doubt was expressed as to the possibility of carrying on profitable operations at the Jupiter mine on an enlarged scale, for it cannot be said that the natives are in any way fond of working in the deepest mines of the Rand, when, as a rule, only an ample supply of labor can be obtained when the outcrop or shallower mines have plenty of help. Under these circumstances, two working policies presented themselves to the directors, the first being to mill on a reduced scale and adopt an ultra-selective mining policy, and the second being to suspend milling operations for the present and proceed with shaft-sinking into the still deeper areas of the mine, in the hope of finding ore of a higher grade. If the advisability of carrying out either of these working policies failed, the only alternative would be to close down all operations at the mine and so conserve the cash resources of the Company until a suitable opportunity and time arrives for working the mine on an enlarged scale, and increasing the capacities of the ore-reduction plant to 60,000 tons per month. After mature consideration it was not considered a sound mining policy to adopt a strict selective-mining method, whereby most if not the whole of the best ore reserves would be depleted in quite a short time, leaving a balance of such poor ore as to render its profitable extraction an impossibility in the future. To stop milling operations temporarily, and expend the cash resources of the Company in prospecting by shaft-sinking the still deeper unproved areas, did not offer much attraction, for it seemed doubtful whether the deeper areas would, if proved, contain ore of a higher average value than \$4 per ton, even if these operations were confined to the Howard or richest part of the mine. It was therefore decided that, with the present paucity of native labor, the continuance of milling operations was impracticable, that the present cash in hand was not sufficient to put the mine and mill into a condition to produce and treat 60,000 tons per month, and that under the circumstances it was deemed best to suspend all work at the present and await the arrival of a period, accompanied by conditions as to native labor and otherwise, when it will seem possible to place the mine in a permanently satisfactory position.

General Mining News

ALASKA

FAIRBANKS

According to figures prepared by Frank Cook, agent at Fairbanks for the Wells Fargo & Co.'s Express, the output of the Fairbanks district for the year 1913 will be practically a million dollars less than for the previous year. The causes for this are various and hard to be determined, but many of the prominent men of the district attribute it in great part to the shortage of water during the past summer. The following is a list of shipments of bullion for the year 1913:

Fairbanks district	\$3,469,321
Hot Springs district	215,579
Ruby district	70,585

Total\$3,755,485

The output of the Tanana valley since its discovery in 1903 is approximately \$63,460,000.

JUNEAU

The Alaska Treadwell Mining Co. reports as follows for October:

Development, feet	356
Stock of broken ore decreased, tons.....	33,674
No. 1 mill, 240 stamps worked, days.....	29.90
No. 2 mill, 300 stamps worked, days.....	30.45
Total ore crushed	79,961
Gold by amalgamation	\$125,237
Gold by cyanidation of 1705 tons of concentrate...	110,526
Realizable value	233,406
Net profit	135,005

On account of ore from the 1320 and 1460-ft. levels being low grade, and because of the caving of the hanging wall, ore from the upper levels has not kept up its grade, the Alaska Mexican company lost \$3262 in October. The 120-stamp mill worked 30.6 days and crushed 18,606 tons of ore, yielding \$24,651. Operating expenses were \$23,267 and construction \$4646. The ore averaged \$1.34 per ton.

Suit has been entered in the Superior Court of California, for the county of Alameda, by F. L. Morris and H. H. Patterson against B. L. Thane, for an accounting and further share of the commission received in connection with the sale to the Alaska Gold Mines Co. of the Sheep Creek, Ground Hog, and Silver Bow mining claims, and the Salmon creek and Granite creek water rights, including the 300 hp. of developed hydro-electric power. These properties were owned jointly by Messrs. Morris, Patterson, Thane, and J. R. Whipple, and, according to the papers in the case, Mr. Thane was authorized to sell them, it being agreed that the proceeds should be divided equally among the four. He received 9000 shares in the Alaska Gold Mines Co., which were duly divided. However, he also received a contract as manager at a salary of \$10,000 per year and 12,000 shares to be transferred in installments in the course of three years. It is claimed that these 12,000 shares were not in fact salary but part of the consideration for the property and as such properly subject to division among the parties in interest.

ARIZONA

GILA COUNTY

(Special Correspondence).—At the Arizona Commercial, cutting the station at the 1300-ft. level is almost completed and the shaft is rapidly nearing a depth of 1400 ft., at which point sinking will be temporarily suspended. At the Superior & Boston the vein on the No. 6 level, which was sharply cut off by a mass of diabase, has been re-discovered through the aid of the diamond-drill hole which was started some time ago under the direction of E. Sweeney. At the Black Warrior, which is under lease to Snell & Fiske, operations were temporarily suspended because of the impassable condition of the roads. During the first 15 days of November about 650 tons of ore was shipped to the El

Paso smelter, averaging 6.2% copper. Under normal conditions 54 men are employed, the daily output averaging 44 tons. The Gibson lessees are shipping 200 tons of copper ore to the Old Dominion smelter.

Miami, November 26.

MOHAVE COUNTY

The Tom Reed mine produced gold worth \$110,000 during the past month. From the Gold Ore mine, regular shipments are being made by auto-truck to the Gold Road mill. The ore averages \$11.50 per ton. A hoist is being erected at the Cone Mining & Milling Co.'s claim, west of the Boundary Cone and southwest of the Tom Reed. Rich ore has been cut at a depth of 95 ft. At the Golconda, the shaft is to be sunk from 495 to 700 ft. This mine yields zinc ores. The molybdenite deposits in Copper cañon have been inspected by F. W. Horton of the U. S. Bureau of Mines. Sixteen miles from Kingman is the C. O. D. mine, which produces gold, silver, and lead ores, and recently it was optioned to Qualey Bros. of New York.

FINAL COUNTY

The Gunn-Thompson interests have decided to erect a 500-ton concentrating plant on their property, the Magna, at Superior. The Calumet & Arizona Copper Co. is employing a large force of men in its mines there.

CALIFORNIA

October's oil operations showed a decline in production and an increase in consumption, details being as follows:

New rigs	27
Wells drilling, active	310
Wells drilling, idle	388
Producers, active	5,675
Producers, idle	1,250
Abandoned wells	15
Production from 16 fields, barrels.....	7,839,917
Decrease against September, barrels.....	416,793
Total stocks on hand, barrels	49,309,700

MONTEREY COUNTY

(Special Correspondence.)—At Parkfield, the Kings Quick-silver Mining Co., a Canadian corporation, has opened a body of low-grade cinnabar, reported to be free from other sulphides than the mercury sulphide. A 75-ton concentrating plant will be built soon. A 10-ton Scott furnace is being installed at present to be used for treating higher grade ore and concentrate. The whole equipment will be working by next spring, the machinery being constructed by Fairbanks, Morse & Co. A. A. Lewis is superintendent of the property. This Company attracted much unfavorable notice in Toronto by reason of its methods of promotion and the effort to make a mine will be watched with interest.

Parkfield, November 25.

NEVADA COUNTY

A dividend of 6 cents per share, equal to about \$30,000, will be paid by the Brunswick company of Grass Valley. Chris Mallen is superintendent.

PLACER COUNTY

(Special Correspondence.)—The Glenn Consolidated Mining Co.'s property, on the upper Forest Hill divide, 8 miles above Last Chance and 60 miles from Auburn, has been bonded to F. J. Moss of Auburn. G. McAuly is president of the Company and G. R. Cowan a large shareholder. The mine has been watched by local men for a considerable time. Adjacent to it are the Blue Eyes and Pine Nut claims. The area has never been properly prospected. Seven gravel channels run through the divide, and have been very profitably worked at Last Chance. Above the gravel is a lava cap of about 600 ft. in thickness, the gravel averaging 5 ft. depth.

Auburn, November 25.

PLUMAS COUNTY

In the suit of J. J. Reilly v. the Seneca Mining & Milling Co., heard before the United States Circuit Court, it was agreed that the plaintiff is owner of the Del Monte lode claim near Seneca, and that all of the lode on the property, as well as the extension of the same vein downward through the White Lily and Wedge claims of the de-

fendant, also belongs to the plaintiff. This vein apexes on the Del Monte claim, and in 1909, 1910, and 1911 the defendant extracted ore worth \$50,000, judgment for which was entered.

SACRAMENTO COUNTY

During September the Natomas Consolidated company's

REPAIRING NATOMA NO. 6 DREDGE.

dredges at Natoma yielded gold worth \$198,621, the profit being \$94,864.

COLORADO

GUNNISON COUNTY

The Kubler mine at Mt. Carbon is to be closed for the winter, and the men who are now working there are to be transferred to the Alpine mine. About 50 tons of coal was being mined per day, and 100 tons is being mined at the Alpine mine, and this will be increased materially when the men from the Kubler mine begin work at the Alpine. The tounage will be increased throughout the winter.

TELLER COUNTY (CRIPPLE CREEK)

On December 1 a cave-in occurred in the Golden Cycle mine, and three men were entombed. Strenuous efforts are being made for their release. Owing to the coal miners' strike in southern Colorado, it has been difficult to get bituminous coal for the mines, so lignite, which is obtained easier, is being burned at several mines, using the Parkinson patent furnace. On December 1, the Golden Cycle shareholders received \$45,000 as a dividend, making a total of \$405,000 for the year.

Estimates of the November output of the district are as follows:

Where treated.	Tons.	Average value.	Gross value.
Smelters	3,985	\$65.00	\$259,025
Golden Cycle	34,100	20.00	682,000
Portland, Colorado City..	9,500	22.00	209,000
Portland, Cripple Creek..	16,200	2.76	44,712
Stratton's Independence..	10,107	2.92	29,512
Colburn-Ajax	5,000	4.00	20,000
Gaylord-Dante	1,400	3.00	4,200
Wild Horse	1,200	3.40	4,080
Kavanagh-Jo Dandy	1,600	2.20	3,520
Isabella mines	700	3.00	2,100
Total	83,792		\$1,258,149

One hundred feet of a 3-compartment shaft has been sunk by Joe Acton at the Chicken Hawk mine on Guyot hill in 20 days. Two Ingersoll-Rand jack-hammer drills were used, drilling 18 to 20 holes per round in granite. The contract for 250 ft. of sinking is nearly finished, and the shaft will eventually be 1250 ft. deep. The Mary McKinney Mining Co.'s shaft is down 1013 ft. The Doctor-Jack Pot Mining Co. reports that during the second and third quarters of the year, 3662 tons of \$15.95 ore was shipped; and 733 ft. of development was done at a cost of \$3.79 per foot, mostly on No. 9 level. Cash in banks totals \$50,343. There are 12 sets of lessees on the Company's property. The Fountain Valley claim, owned by the Banner company, has been leased to John Kolman, of Cripple Creek, under certain conditions. A dividend of 2 cents per share, equal to \$50,000, has been paid by the Elkton Consolidated Mining & Milling Co. A 200-ton con-

centrating plant is to be erected at the Vindicator Consolidated mine, and foundations are being prepared. The mill was designed by Edward F. Wiard, of Denver. The mine is developing well, and lessees are keeping up their ore production. During the current year, four dividends, totaling \$180,000, have been paid.

THE SAN JUAN

The Tomboy mill treated 11,500 tons of ore in October, yielding \$85,900 from amalgamation, cyanidation, and shipment of concentrate. The profit, including \$4400 from the tramway, was \$35,400. On equipment was spent \$5185, not included in the above.

Operations at the Camp Bird during the third quarter of the year were as follows:

Development, feet	1,151
Stoping, cubic feet	102,860
Broken ore in stopes, tons.....	14,406
Ore treated, tons	7,865
Revenue	\$204,405
Profit	107,367

On No. 4 level, the east drift is in 1281 ft., the last 35 ft. being 4 ft. wide worth \$13 per ton. Raise 626 from No. 6 level, opened some good ore. The east drift on No. 7 level has been driven 174 ft. in \$20 ore for a length of 10 ft., no ore for 24 ft., \$15 to \$20 ore for 20 ft., then no further ore.

IDAHO

LEMHI COUNTY

The lead-silver mines of Gilmore have been described by Ralph Nichols in the *Transactions* of the American Institute of Mining Engineers. The district was opened in 1880, and the present producing mines are near the terminus of the Gilmore & Pittsburg railroad. The mines are at an altitude of from 7400 to 8300 ft., and winters are severe. There are a number of prospects in various stages of development, while the producing companies are the Pittsburg Idaho, Latest Out Mining & Smelting, and Gilmore Mining. The lodes are fissures in limestone, with a northeast-southwest course, dipping west from 40 to 70°, the ore-shoots pitching south. The ores are oxidized, containing an excess of iron over the silica, the lead minerals being mostly carbonate of lead. A peculiar feature of the deposits is that the sulphides have gradually decreased in depth, also a falling off in lead and silver content. The ore is mined in bulk, requires no concentration, and is a most desirable smelting mixture for Salt Lake markets. Lead content varies from 25 to 45 per cent. Since 1910, the properties mentioned have shipped over 100,000 tons of ore.

SHOSHONE COUNTY

An interesting table has been compiled by the *Wallace Miner* showing the results of operations in the Coeur d'Alenes during the past 11 years. The following properties have contributed to the table below: Cleveland, Coeur d'Alene Development, Bunker Hill & Sullivan, Empire State-Idaho, Frisco, Gold Hunter, Golden Chest, Hecla, Hercules, Larson & Greenough (Morning), Standard, Federal Mining & Smelting, California Consolidated, Snowstorm, Tamarack & Chesapeake, Pittsburg Lead, Success, Marsh, Caledonia, Ontario, and various lessees.

Ore mined, tons	15,503,942
Gross value	\$138,354,991
Net profit	36,215,027
Losses	955,304
Output for 1913, estimated	18,000,000
Profit for 1913, estimated	4,000,000

Five feet of good silver-lead ore has been opened for 20 ft. on the 1600-ft. level of the Hecla mine at Burke. It is said that the Marsh mine, adjoining the Hecla, may be purchased by F. A. Helnze. Lessees at the Bear Top-Orofino mine, near Murray, are shipping silver-lead ore. Six feet of copper ore has been opened in the adit at the Iron Mask. Under the laws of Arizona the Any-Matchless Mining & Milling Co. has been organized with a capital of 1,250,000 shares at \$1 each. Several claims on Pine creek, where a great deal of work has been done, will be developed. The construction of an electric railway between Wardner and

Kellogg for freight and passengers is proposed by the people of the district. On Thursday, December 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 195, of \$81,750. This makes the total amount of dividends paid \$14,729,250.

MICHIGAN

HOUGHTON COUNTY

The Calumet & Hecla Mining Co. is preparing to open a series of test pits on the Frontenac and Manitou tracts, about 1½ miles south of the Delaware mine, for the purpose of establishing the relation of several cupriferous beds in these tracts with a number of formations disclosed in the recent diamond-drill operations of the Cliff Mining Co., eight to ten miles distant. The exploratory work on both tracts is under the direction of C. D. Hohl, formerly chief engineer of the Tamarack mine, recently appointed geologist for the Calumet & Hecla and subsidiary companies.

The Western Federation of Miners is making all kinds of rash statements regarding the mines and their ownership, and continues to fool the striking miners. On November 25, several men were tried before Justice Jacola for various assaults, the following names giving an idea of the different nationalities employed in the district: Korpac, Rosen, Steva, Karensky, Mesich, Orlich, Blma, and Stimac.

MONTANA

FERGUS COUNTY

The Barnes-King Development Co. reports as follows for October: ore treated, 5300 tons, yielding \$32,884; expenses, \$18,550; balance, \$14,334; of this, \$10,750 went toward part payment for the North Mocassin property, leaving \$3583 for the Barnes-King company.

JEFFERSON COUNTY

Negotiations are in progress between interests said to be identified with the Boston & Corbin and the Livingston Smelting & Refining Co. for the acquisition by the former of property of the Alta company at Corbin. The Alta was one of the old-time famous silver-lead producers of Montana. A large concentrator was operated in conjunction with the mine at Corbin. Suspension of work, with the exception of lessees, occurred in the early nineties, the ore becoming poor, which, with the decreased price of silver, made operations unprofitable. Results obtained by lessees have been encouraging.

LEWIS AND CLARK COUNTY

Active operations in the Stemple district, situated in the 'Seven-Up Pete' gulch, are being conducted at the Rover, Lockey, Ibex, Reliable, Munroe, Last Chance, and Black Hawk mines, which produce gold and silver ores. These are hauled 30 miles by wagon to Silver. At their own expense the miners have recently constructed 11 miles of road, and one county commissioner stated that the county ought to start building some good roads.

SILVERBOW COUNTY

The most important development work of the Corbin Copper Co. is at the Gambrinus group of claims at Butte. Satisfactory arrangements have been made with the city of Butte permitting the sinking of a working shaft on the Gambrinus claim. The surface plant is completed and necessary machinery installed. The shaft is down 200 ft., and the location of the western extension of the Anaconda vein has been proved by cross-cuts at the 100 and 200-ft. levels. Four payments of \$15,000 each have been made on this property, and the balance or final payment of \$90,000 will be due January 17, 1914. It is to make this payment and continue sinking the shaft that an assessment of \$1 per share has just been called. The Company is also continuing exploration on the Rochester claims. The option on these claims which expired in September 1913 was extended to March 1914. The exploratory shaft is down 500 ft. and the cross-cut at this depth is within a short distance of the vein. Several stringers carrying copper were cut by this cross-cut and commercial ore is expected when the vein is reached. The vein is an immense quartz fissure, 160 ft. thick, and on the surface shows copper-stained material on both walls.

NEVADA

ESMERALDA COUNTY

According to the report of Albert Burch, general manager, the Goldfield Consolidated Mines Co. had the following results in October:

Ore treated, tons	30,486
Net realization	\$146,918
Costs:	Per ton.
Minng (stoping and development)	\$3.58
Shipping expense	0.23
Dump moving	0.04
Transportation	0.08
Milling	1.75
Marketing	0.04
General expense	0.33
Bullion tax	0.13
Flood damage	0.01
Total costs	\$6.19
Miscellaneous earnings	0.08

Net costs\$6.11

Development covered 3088 ft. at a cost of \$5.52 per foot. In general, the development work for the month did not result in the addition of any important orebodies, though some of them showed improvement in size and value toward the end of the month.

Work in the Combination yielded no pay-ore, but the 301-G and 328-N stopes, which are southerly extensions of the old Hampton stope, were nearly doubled in floor area. In the Mohawk the 176 drift northerly from the Sheets-Ish stopes produced 142 tons of \$8 ore; and the 3-R sill in the same ground was extended and produced 52 tons of \$12 ore. A cross-cut on the new No. 1 level near the Oddie shaft passed through 20 ft. of ore and produced 135 tons of \$10 ore. The 130 drift on No. 1 level, about 200 ft. southwest of the Mohawk shaft, was extended and produced 17 tons of \$12 ore. The 490 stopes below the old 354 orebody were largely increased in floor area. Very little development was performed in the Red Top-Laguna mines and no discoveries of importance were made. Most of the work in the Clermont-Jumbo mines was confined to the No. 8 and 9 levels, and while some good assays were obtained at some points, no orebodies of commercial size and grade were developed.

HUMBOLDT COUNTY

The new orebody found in the Seven Troughs Coalition was opened about 50 ft. below No. 10 level by a cross-cut from a winze sunk in the foot-wall. There seemed to be a considerably disturbed country for some distance between where the vein was lost and where picked up again. The present work is identical with that above where the vein was regular, persistent, and highly mineralized close to 1000 feet.

LINCOLN COUNTY

In October the Prince mine at Pioche shipped about 5400 tons, and the present output is 175 tons per day. Fifty men are employed.

LYON COUNTY

The Mason Valley Mines Co. reports the following for the quarter ended September 30, 1913:

Mason Valley ore treated, tons	25,986
Custom ore treated, tons	21,469
Total	47,455
There was produced 2947 tons of matte which yielded 2,707,719 lb. of refined copper.	
The financial results of the quarter's operations are as follows:	
Gross operating profit	\$33,187
Less depreciation	\$28,296
Less deferred charges	3,644
Less bond interest	14,040
	45,980
Net deficit for the quarter	\$12,793

MINERAL COUNTY

The Lucky Boy adit is in 3000 ft., but it is estimated that another 2700 ft. must be driven to cut the main vein. Several small veins have already been cut, but not opened. The adit is 7 ft. high clear of timber, is electrically lighted, is supplied with fresh air by pipes, a covered drain carries off the flow of water, and machine-drills and electric blasting are in use.

NYE COUNTY

The annual meeting of the Jim Butler Tonopah Mining Co. was held at Philadelphia on November 12. The report of Frederick Bradshaw, the general superintendent, includes the following: During the year 6520 ft. of development was done. The workings on the sixth level of the Wandering Boy shaft are entirely in trachyte, the ore-bearing formation, with the exception of that in the north cross-cut from the winze on the seventh level, at a distance of 120 ft. from the vein, a block of West End rhyolite has been encountered which probably has no effect on the Fraction vein.

Ore shipped to Belmont mill at Millers, tons.....	18,900
Gross value	\$374,903
Net returns from treatment	224,954
Expenditure on wages, power, etc.....	109,693
Cash in banks	100,694
Loans on collateral	25,000

Total at September 30, 1913.....	\$125,694
Balance a year ago	2,965

STOREY COUNTY

On November 21 new equipment arrived at Gold Hill for the Yellow Jacket, Crown Point, and Belcher mines, consisting of two Byron Jackson two-stage, electrically driven pumps, transformers, and two 200-hp. Westinghouse motors. The pumps have a capacity of 1500 gal. per minute, and are to be installed in the joint Crown Point-Belcher incline. They will unwater the mines from 1400 to 1700 ft. At the C. & C. pumping shaft the water has been kept at 5 ft. below the 2500-ft. level.

NEW MEXICO

GRANT COUNTY

The Cleveland group of zinc claims in the Pinos Altos district, belonging to G. H. Utter, of Silver City, have been acquired by the Empire Zinc Co. for over \$200,000 cash.

SOCORRO COUNTY

Twenty-four bars of gold and silver bullion, weighing a little over a ton, were shipped from the Socorro company's mill to the mint, being the result of the first half of November. Eight tons of concentrate was sent to the smelter.

ERNESTINE POWER-PLANT, MINE, AND MILL.

A pipe-line for air is being laid at the Little Charlie mine. Electric equipment at the Pacific is almost complete. At the Maud, the 500-ft. level drift is to be extended. The Oaks Co. is driving from a winze from the B adit, and sinking is still under way.

SOUTH DAKOTA

LAWRENCE COUNTY

The Homestake Mining Co., of Lead, on November 26 notified its employees that every man of them would receive

a Christmas present of 7% of his annual salary. The amount donated by the Company for this purpose is \$150,000.

UTAH

Work on the 6000-ft. tunnel, which when completed will provide drainage and transportation for the mines of Alta, has been started. The tunnel is now 350 ft. long, and when completed it will cut the Alta properties 600 ft. deeper than the lowest developed point in the district. One shift is employed at present, and ample protection has been made against snowslides. R. L. Mack is superintendent.

SALT LAKE COUNTY

During the fiscal year ended August 31, 1913, the Utah Apex Mining Co., which produces lead, copper, silver, and gold-bearing ores, had the following results:

Gross value of ore sold.....	\$803,928
Royalties and miscellaneous income.....	18,897

Total	\$822,825
Mining	233,247
Milling	37,171
Freight and smelting	272,200
General, taxes, etc.....	42,943
Interest, etc.	12,488

Profit	\$224,774
Depreciation	94,585
To profit and loss account.....	\$130,189

The miners' strike, during the latter part of 1912, interfered with operations; also the smelters have caused ore shipments to vary from 400 to 100, then to 300, and finally to 100 tons daily, as at present. This is unfortunate and increases costs considerably, but a remedy will be found for the trouble. By sinking the Parvenu shaft it is figured that the ore reserves will be greatly increased.

A curious affair has arisen at the Utah Apex mine. About two weeks ago a Mexican named Lopez killed a man at the Highland Boy mine. During his flight from capture he has killed five other men, and at last got into one of the adits of this property. The authorities have blocked all openings save one, and are trying to smoke the fugitive out of the mine.

SUMMIT COUNTY

It has been decided to work a portion of the Wasatch Mines Co.'s property by leasing. The Company owns 61 claims in the Little Cottonwood district, and a large output has been made since the start of operations. As soon as conditions are favorable for financing the property, the Company will start active development again.

UTAH COUNTY

High-grade lead-silver ore is being shipped from the Pacific mine in American Fork cañon. All equipment has been covered for winter work. Development is under way at the Dutchman, Comstock, Yankee, and Lehi-Tintic.

WASHINGTON

CHIELAN COUNTY

(Special Correspondence.)—The Golden Eagle Mining Co. has made tests in cyaniding its ore during the past summer, with satisfactory results. The gold is in quartz and serpentine, is very fine and flaky, much of it having been lost in stamp-milling heretofore on this account. The ore was crushed dry and conveyed to leaching vats, giving an extraction of about 80%. A 100-ton plant is planned to be in operation next summer. On the North Star claim, owned by this Company, an 800-ft. adit will be driven this winter to cut the vein at a depth of 800 ft. A. G. Clark, of Seattle, is the principal owner.

Litigation is in progress over the principal groups of claims in the Blewett district, these claims being the Peshastin, Fraction, Humming Bird, Bobtail, and Culver. Under various managements they produced considerable gold from 1890 to 1905; the U. S. Geological Survey reports three million dollars. Of late years they have produced nothing but squabbles.

Seattle, November 15.

FERRY COUNTY

(Special Correspondence.)—Mine owners and other consumers of power in the Republic district appear to be undecided whether to use a Diesel engine or electric power from British Columbia. It is stated that a transmission line will be constructed from Republic to Nelson, where a connection can be made with the main line of the West Kootenai Power Co. This work will occupy about 60 days. A 5-stamp mill is to be erected by George W. Steele, of San Francisco, at the Silver Creek mine at Keller camp, 50 miles

GOLDEN EAGLE MILL, BLEWETT, WASHINGTON.

south of Republic. The Gold Chord Mining & Milling Co. owns this mine. The British Columbia Copper Co. has about 300,000 tons of gold, silver, copper, and lead ore blocked out in the Lone Star and Washington mines, on the international boundary. Considerable equipment is to be installed.
Republic, November 28.

STEVENS COUNTY

Approximately 6 ft. of ore of shipping grade is showing in the 100-ft. winze from the main working adit of the Butte-Chewelah mine, near Chewelah, and there is also a promising showing of high-grade ore in the face of the cross-cut.

WYOMING

BIGHORN COUNTY

At a depth of 1660 ft. the Utah-Wyoming Consolidated Oil Co. has started a flow of natural gas in No. 6 well equal to about 7,000,000 cu. ft. per day. The pressure is 800 lb. per square inch at present, and drilling will be continued as far as possible. No. 3 well is down 700 ft., and the gas from No. 5 is to be marketed.

CANADA

BRITISH COLUMBIA

Part of the Old Sport group of copper claims, in the Ella Mountain district, near the north end of Vancouver island, have been sold by Conrad Wolfe and associates of Spokane for about \$500,000. It is stated that the control will be held by men interested in the Stewart mine of Idaho. About \$30,000 has been spent on development during the last four months, and it is now proposed to con-

struct an electric railway 18 miles from the coast to the property. So far this year, the companies operating in the Kootenai-Boundary district have paid \$1,754,875 in dividends, the following being the principal contributors: Granby, \$673,000; Standard, \$550,000; Consolidated Mining & Smelting, \$220,000; Hedley, \$160,000; Le Roi No. 2, \$43,200, and British Columbia Copper, \$88,675. From the Standard mine, at Silverton, 2500 tons of zinc ore is being sent to Argentine, Kansas, for treatment. During the current year a total of 3767 tons of zinc ore and concentrate has been shipped from Slocan mines. During the third week in November the Granby smelter treated 24,183 tons of ore yielding 435,000 lb. of copper, making totals of 75,699 tons, and 1,307,000 lb. for the three weeks, respectively.

ONTARIO

The pumps at Kerr lake are still working, and will continue until the water and mud in the bottom gets too hard, when they will be shut down for the winter. During the week ended November 22, ore shipments from Cobalt totaled 549 tons, and also 193,321 oz. silver. The year's bullion shipments total 8,136,882 so far. Bullion is being sent to London again owing to a final reduction of rates. Changes in these rates have been \$4.50 to \$7.50, \$7.50 to \$6, and \$6 to \$5 per 100 pounds. The Chambers-Ferland company will lease 30 stamps of the Northern Customs mill for five years, when extensions to the plant are completed. On December 15 the Trethewey Cobalt Silver Mines Co. will pay a dividend amounting to \$50,000, making a total of \$1,012,598. In October the mill treated 3225 tons of ore yielding 62,000 oz. of silver, with 84% recovery. The Hudson Bay mill treated 1742 tons of ore in October, yielding 38,306 oz. silver with 86% recovery. At the Temiskaming mine, the shaft is being sunk from 650 to 725 ft. depth.

The Porcupine Crown mine is opening in a promising way, and the mill is now treating from 85 to 100 tons of ore per day. Results at the McIntyre during October were as follows:

Ore treated, tons	4,131
Value of bullion	\$41,098
Extraction, per cent	95.50
Running time of mill, per cent.....	96.77
Costs:	Per ton.
Mining	\$1.806
Development	1.938
Milling	1.425
General	0.964

Total\$7.133

At the present time C. H. Henrotin and Frank Loring are engaged in sampling the Burnside, Tough-Oakes, Wright, and Robbins claims at Kirkland lake for an English syndicate.

COLOMBIA

The Pato dredge of Oroville Dredging Co., Ltd., handled 24,100 cu. yd. of wash yielding \$15,900, during the last week of October.

MEXICO

GUANAJUATO

Three lots of ore and six of concentrate were shipped from the Guanajuato district to the Aguascalientes smelter during the last week of October. The 31 tons of ore was worth \$12,400, and 102 tons concentrate at \$49,400.

HIDALGO

(Special Correspondence.)—At La Blanca mill extensive changes are in progress. Its capacity is being increased to 500 tons per day, and the agitation is being altered from the intermittent to the continuous system.

Pachuca, October 10.

JALISCO

During October the El Favor mill produced bullion valued at \$45,000. Returns from ore sent to the Aguascalientes smelter are not in so far. A 25-ton concentrating plant is to be erected at the Zapote copper mine in the Ameca district. This property is controlled by the Mutual Mining & Milling Co. of Mexico City. L. C. Grace is manager. A

new mill is being erected at the San Pedro Analco mine, owned by San Rafael y Anexas Co. Clive S. Newcomb, of Mexico City, is in charge of the work.

The Cinco Minas mining camp, in the Hostotipaquillo district, was entered during the second week of October by a band of rebels variously reported as numbering between 200 and 400 men. The rebels forced a loan from the Company for \$1000 and looted the store. About the same time a small band of rebels from Tepic entered the camp of the Amajac Mining Co., a Pennsylvania concern, in the Hostotipaquillo district.

MEXICO

October returns of the Mexico Mines of El Oro and El Oro Mining & Railway companies are as follows:

	Tons.	Yield.	Profit.
Mexico Mines	13,430	\$141,500	\$83,700
El Oro	21,560	177,860	64,140

SONORA

(Special Correspondence.)—The old Babicanora mine was bought about eight months ago by Mr. Brongler and has been put in working order, including considerable timbering and cleaning out. The vein is a strong one, trace-

LA BLANCA MILL, PACHUCA, HIDALGO.

able 3500 ft. on the surface. It runs east and west and seems to be a continuation of the Chispas vein. A great deal of work has been done on it and a large amount of rich ore has been extracted during the last 300 years. Twenty-eight inches of ore averaging \$30 per ton has been found in the bottom. An underground hoist is to be installed and development work will be started about December 15. Mr. Frazier, of Los Angeles, is superintendent, and E. Frey, of Goldfield, is foreman. The former is in the States at present to buy hoisting machinery. The country is quiet and no harm has been done by rebels.

Arizpe, November 1.

The Lucky Tiger-Combination Gold Mining Co., of Kansas City, Missouri, controlling the Tigre Mining Co., operating at El Tigre, reports as follows for October:

Ore crushed, tons	6,525
Cyanide plant, tons	8,199
Value of products:	
Shipping ore	\$ 16,166
Concentrate	53,920
Bullion	71,992
Total	\$142,078
Costs, including marketing and taxes.....	81,382
Profit	\$ 60,696
Dividend paid November 20, cents per share.....	6
Total to date	\$2,011,552

WESTERN AUSTRALIA

September returns from some of the mines are as follows:

	Tons.	Yield.	Profit.
Associated	10,945	\$60,000	\$2,400
Associated Northern	8,712	59,000	7,000
Bullfinch	5,545	68,000	43,000

Personal

C. W. MOASE is at Butte, Montana.

JOHN B. FARISH is at Santa Barbara.

AUGUSTUS HEISE is in San Francisco.

H. V. WINCHELL has gone to Colorado.

C. W. MERRILL is back from New York.

M. P. BOSS is at Sacramento, California.

D. C. JACKLING has returned from Juneau.

CARL S. FOGH was in New York last week.

H. C. CALLAHAN has returned from Europe.

G. W. METCALFE has been in San Francisco.

W. H. ALDRIDGE was in San Francisco this week.

M. K. RODOERS passed through San Francisco Tuesday.

F. DANVERS POWER is in New York and will go to London.

P. A. KEEGEL of Los Angeles was in San Francisco Thursday.

S. H. BALL visited San Francisco and the Comstock last week.

JAMES G. BERRYHILL is living in San Francisco this winter.

W. G. PERKINS was in San Francisco, returning from Korea to London.

C. F. RAND has gone to Cuba, expecting to return to New York, December 16.

R. S. BLACK, manager of the Kaigurli mine, Kalgoorlie, has gone to England.

M. H. KURYLA is in New York, on his way to San Francisco from Mexico City.

S. GREGORY, managing director of Minerals Separation, Ltd., has sailed for London.

FREDERICK H. MORLEY has joined the editorial staff of the *Mining and Scientific Press*.

H. W. HARDINGE, who returned from Russia in September, was in San Francisco this week.

ALBERT H. FAY, of the U. S. Bureau of Mines, is visiting California and other Western states.

L. H. WEBB sailed on the *Carmania*, November 29, for Europe, to investigate metallurgical processes.

H. C. BELLINGER has resigned from the management of the Great Cobar copper mine, New South Wales.

DAVID H. LAWBRANCE, manager for the West Mexico Mines Co., of Baja California, is at present in the United States.

C. F. TOLMAN, JR., will address the Le Conte Club, at the University of California Club, tonight on the 'Cycle of Desert Erosion.

DWIGHT E. WOODBRIDGE is in the Monte Cristo country of Washington, and expects to be in New York state much of the winter on iron ore examination.

OTTO WARTENWEILER has completed his work as mechanical engineer in charge of construction of the 400-ton mill of the Commonwealth M. & M. Co., and opened offices in Los Angeles.

GEORGE F. WADDELL has resigned as superintendent of the Steptoe Valley Smelting & Mining Co.'s concentrator at McGill, Nevada, to become general manager of the Ohio Copper Co.'s property at Bingham and Lark, Utah.

F. W. MORGAN, who was manager of the Bullfinch mine and well known throughout Western Australia, died several weeks ago. A. L. HAY, manager of the Hainault, Kalgoorlie, before its absorption by the South Kalgoorlie, has been appointed manager.

THE annual meeting of the Engineers' Club of San Francisco will be held next Saturday night at the club rooms in Hotel Sutter.

THE next regular meeting of former students of the Freiberg Bergakademie will be held on December 20, in the Hofbrau Haus, New York City. This is the annual meeting, and election of officers will take place. All former students of the old mining school should communicate with the secretary, C. L. BRYDEN, 1701 Jefferson avenue, Scranton, Pennsylvania.

New York Metal Market Review

Dullness and a decline in prices characterized every metal in the month of November. The demand for finished brass and copper products fell off to such an extent that many of the mills did not operate full time. In a few weeks electrolytic copper has dropped over 2c. per pound. Spelter declined about 10 points during the month and in having dropped no further was considered to have held up fairly well. Lead was quiet, but competition for what business there was caused the largest producer to lower its price \$2 per ton. Antimony was without feature of especial interest. The tin market proved a disappointment to importers and dealers, inasmuch as expected business did not materialize. Aluminum was stagnant and, as with all the metals, quotations declined repeatedly. The metal trade is doing much mental speculation as to the causes of the general slump. To the tightness of money, which is charged to the currency reform agitation, is credited a good part of the slowing up in operations, but the new tariff is more generally held responsible. What is going on, in the opinion of many dealers, is the predicted readjustment of values, pending which large consumers are limiting their buying to the minimum. They are not disposed to buy freely until the bottom is reached.

COPPER

At the beginning of November, consumers were letting the market severely alone, and they continued to do so pretty much all of the month, and nominal prices were the rule. November 1, quotations were at or near 16.87½c. cash for Lake, and 16.50c. for prompt electrolytic. Resale lots in limited quantities were offered and occasionally pressed for sale, and these usually made the market when there were any dealings at all. Early in the month complaint became more acute that the business of consumers was falling off. This condition did not mend, and toward the end of November it was definitely stated that several of the brass and copper mills in the Naugatuck valley had reduced their working time to five and in some cases four days per week. Melting had lessened to such a degree that considerable October copper had been carried into November, and some of that delivered in the latter month would be carried into December. With the metal carried over and the comparatively small amount bought in November, buying for December, it was seen, would fall below expectations. The second week of the month brought a further decline, electrolytic being quoted November 12, at 15.50c. cash for prompt delivery and 16.25c. for Lake, the latter price being entirely nominal. Until about this time the big agencies had held to their price of 16.75c. cash for electrolytic, but there began to be heard rumors that the producers and their selling agents were willing to sell to Europe on a basis of 16c. f.o.b., while others were anxious to get domestic business at concessions. The Producers' statement for October, issued November 7, showing an increase of 2,773,288 lb. in stocks, created very little comment and in no way changed the trend of the market. By November 17 electrolytic was down to 15.25c. cash for November and 15.12½c. cash for January and February, with Lake nominal at 16c. In electrolytic a fair business was done, chiefly for export at these figures, it being estimated that between 10,000,000 and 15,000,000 lb. was bought. In this movement, which was regarded as below normal in point of quantity, some, but not all, first hands were sellers at 15.25c. The January and February price of 15.12½c. was made by second hands. Lake was inactive. By November 20 complete quiet had set in again with prices still sagging. Quotations for prompt electrolytic had dropped by November 26 to 14.75c. cash, at which price some sales were made, particularly to Europe. Lake was nominal at 15.50c. A carload of high-grade Lake was sold November 24 at 16c., the seller having paid 17.25c. some weeks before. He took his loss of 1¼c. per pound cheerfully and said he was glad to dispose of the carload at the price he obtained. The one optimistic view taken of the situation at this writing is that consumers' stocks are very low and that when the turn in the market does come the recovery will be as thorough and as rapid as the slump. Many find it difficult to

believe that consumption has fallen off as completely as the stagnant market would seem to indicate. Exports to November 27 were 23,918 tons. The Waterbury average for October was 16.87½ cents.

SPELTER

The month opened with spelter at about 5.40c. New York and 5.25c. St. Louis. By November 27 quotations had dropped to 5.25c. New York and 5.10c. St. Louis. Dullness prevailed continuously to the latter date and there were no features of interest. In view of the fact that consumption had fallen off to a considerable degree it was pointed out that in losing only 10 points or thereabouts spelter prices had held up fairly well.

LEAD

During the greater part of the month independent producers undersold the American Smelting & Refining Co., and as a result the big interest on November 26 reduced its price \$2 per ton and its quotations of 4.35c. New York and 4.20c. St. Louis, which had been adhered to throughout November, came down to 4.25c. New York and 4.10c. St. Louis. A fair activity in the closing days of October evidently supplied consumers for most of their needs of the next month, for following the activity the market was uniformly dull aside from a minor routine business for which there was sharp competition.

ANTIMONY

Late in October there was a slight superinduced flare-up in antimony, but it did not amount to much. Prices declined, the month opening at 7.25 to 7.37½c. for Hallett's, 7.62½ to 7.75c. for Cookson's, and 6.50 to 6.75c. for Chinese and Hungarian grades. November 26 quotations were 7.12½ to 7.25c. for Hallett's, 7.40 to 7.50c. for Cookson's, and 6.25 to 6.50c. for Chinese and Hungarian. The market was dull and without feature, except that the duty under the new tariff was a mooted question, the importers and customs officials having failed to get together on a satisfactory basis of valuation, that is, whether to take the value at the source of production or that in this market. Pending settlement, importers have been paying an excess duty, firmly convinced that they later would obtain a rebate.

PIG TIN

Throughout most of November the trade in pig tin was hampered by the failure of tin plate manufacturers to place orders, and this despite the fact that they had booked many contracts for their produce. It was thought early in the month, when the placing of contracts was stimulated by reductions in tin plate at the mills, that orders for tin would follow, but dealers were disappointed. In anticipation of a good demand dealers loaded themselves up heavily and the metal became concentrated in a few hands, but the end of the month came without the big business expected. Stocks on hand November 1 totaled 2357 tons, and it was felt that a genuine shortage would be felt before the first of December, but this was not the case. The total visible supply October 31, 1913, was 11,857 tons as against 10,735 tons October 31, 1912. The total deliveries in 10 months of 1913 showed a decrease of 3150 tons compared with the same period in 1912. Approaching the middle of the month there was some improvement in buying with the purchases consisting principally of 5, 10, and 15-ton lots, all for quick shipment, which showed that consumers' stocks were low. Throughout November, prices fluctuated between 39.25 and 40.25c. with the lower price prevailing near both the beginning and close of the month. As December drew near it was predicted that contrary to expectations an exceedingly ample supply of the tin would be on hand December 1.

ALUMINUM

Quotations for both domestic and foreign prompt aluminum were on the same level during November. In the first few days of the month the nominal price was 19.75c., about the middle of the month it declined to 19.50 to 19.75c., a few days later came down to 19.37½ to 19.62½c., then to 19.00 to 19.50c., and by November 26 had reached 19.00 to 19.25c. Buyers showed very little interest and at times it was difficult to find anything tangible which might be called the market. As heretofore said, the backwardness of automobile manufacturers in placing orders is left in this metal.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, December 4.

Antimony.....	10-10½c	Quicksilver (flask)	\$40
Electrolytic copper.....	17½-17¾c	Tin.....	44-45½c
Pig lead.....	4 25-5.30c	Spelter	7-7½c
Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.			

EASTERN METAL MARKETS.

(By wire from New York.)

NEW YORK, December 3.—The copper market is quiet and weak with standard, spot, and futures not quoted. The general tendency of the buyers is to hold back and but few sales are reported. Very little copper is being purchased by the American manufacturers and the brass mills are running on reduced time. It is predicted that an increase in both American and European stocks will be shown as a result in the decline in consumption and the expansion in production. Lead and spelter are both quiet and weak. Antimony is dull, with Cookson's quotations at 7.50 to 7.70c.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

The improved tendency of silver, to which attention was drawn recently, has not been altogether maintained. The mainstay has been, and is likely to be, the considerable size of the bear account in existence, according to Samuel Montagu & Co., on November 13. Although this circumstance cannot fall to give support to prices, it is apt to operate with some irregularity for, naturally, bear sales do not fall evenly from day to day, nor do they coincide with the size of the market. Another element of uncertainty at the present time arises from sudden and often unexpected movements of the China exchange. Owing to the heavy rains in the beginning of the summer, followed by a drought in July, the harvesting of crops throughout China had to be delayed from three to five weeks, that is to say, the general movement usually commencing early in October has had to be postponed this year until the beginning of this month. Shanghai cables a stock of \$6,130,000, compared with \$6,225,000 last week. The premium for spot delivery in Bombay to which attention has been drawn is still more accentuated. The largest difference touched during the week has been about 2½%. Information has been received by the Indian mail that, owing to unfavorable crop reports from the United Provinces and the short marriage season, a very large off-take is not expected in the coming year.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

June	17.23	14.71	Dec.	17.37

The copper market was dull last week. On November 24 plenty of copper was available through 'second hand' dealers at 14¾c. per pound, and buying was only in small amounts. The strike at the plant of the General Electric Co. had a depressing effect, since that Company uses about 5,000,000 lb. copper per month. By the middle of the week news of buying in London gave a strengthening touch. The Thanksgiving holiday here coincided with the booking of good orders abroad, but sales on Friday were discouragingly small and the week closed with the market as dull as at the beginning. Exports for the week were reported as 4299 tons.

ZINC

Zinc is quoted as spelter, standard Western brands St. Louis delivery, in cents per pound.

Date.	Average week ending

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending		Nov. 19.....39.00

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked *.

	Min.	Max.
Antimony ore, 50%, $\frac{1}{2}$ ton	\$20.00	\$22.50
Arsenic, white, refined, $\frac{1}{2}$ lb	0.02 $\frac{1}{2}$	0.03 $\frac{1}{2}$
Arsenic, red, refined, $\frac{1}{2}$ lb	0.08	0.08 $\frac{1}{2}$
Asbestos, chrysotile	100.00	350.00
Asbestos, amphibole	5.00	25.00
Asphaltum, refined, $\frac{1}{2}$ ton	11.50	20.00
Barium carbonate, precipitated, $\frac{1}{2}$ ton	40.00	45.00
Barium chloride, commercial, $\frac{1}{2}$ ton	40.00	42.50
Barium sulphate (barytes), prepared, $\frac{1}{2}$ ton	20.00	30.00
Bismuth ore, 15% $\frac{1}{2}$ ton	*250.00	upward
Chrome ore, according to quality, $\frac{1}{2}$ ton	10.00	12.50
China clay, English, levigated, $\frac{1}{2}$ ton	15.00	20.00
Cobalt metal, refined, f. o. b. London, $\frac{1}{2}$ lb	2.50	
Coke, foundry, $\frac{1}{2}$ 2240 lb	15.00	20.00
Diamonds:		
Ballas according to size and quality, $\frac{1}{2}$ carat	70.00	
Borts, according to size and quality, $\frac{1}{2}$ carat	2.00	15.00
Carbons, according to size and quality, $\frac{1}{2}$ carat	55.00	90.00
Feldspar, $\frac{1}{2}$ ton	5.00	25.00
Firebrick:		
Bauxite, $\frac{1}{2}$ M	175.00	
Magnesite, $\frac{1}{2}$ M	190.00	275.00
Silica, $\frac{1}{2}$ M	50.00	65.00
Flint pebbles for tube-mills, $\frac{1}{2}$ 2240 lb	21.00	22.50
Fluorspar, $\frac{1}{2}$ ton	10.00	15.00
Fullers earth, according to quality, $\frac{1}{2}$ ton	20.00	30.00
Gilsonite, $\frac{1}{2}$ ton	35.00	40.00
Graphite:		
Amorphous, $\frac{1}{2}$ lb	0.01 $\frac{1}{2}$	0.02 $\frac{1}{2}$
Crystalline, $\frac{1}{2}$ lb	0.04	0.13
Gypsum, $\frac{1}{2}$ ton	7.50	10.00
Infusorial earth, $\frac{1}{2}$ ton	10.00	15.00
Iridium	55.00	
Magnesite, crude, $\frac{1}{2}$ ton	5.00	7.50
Magnesite, dead calcined, $\frac{1}{2}$ ton	20.00	25.00
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, $\frac{1}{2}$ ton	10.00	25.00
Manganese, prepared, according to quality, $\frac{1}{2}$ ton	30.00	70.00
Mica, according to size and quality, $\frac{1}{2}$ lb	0.05	0.30
Molybdenite, 95% MoS ₂ , $\frac{1}{2}$ ton	400.00	450.00
Monazite sand (5% thorium), $\frac{1}{2}$ ton	150.00	200.00
Nickel metal, refined, $\frac{1}{2}$ lb	0.45	0.60
Ochre, extra strength, levigated, $\frac{1}{2}$ 100 lb	2.00	2.50
Osmiridium, $\frac{1}{2}$ oz	25.00	
Platinum, native, crude, $\frac{1}{2}$ oz	30.00	45.00
Silica lining for tube-mills $\frac{1}{2}$ 2240 lb	35.50	37.50
Sulphur, crude, $\frac{1}{2}$ ton	20.00	25.00
Sulphur, powdered, $\frac{1}{2}$ ton	30.00	35.00
Sulphur, 80%, $\frac{1}{2}$ ton	16.50	18.50
Talc, prepared, according to quality, $\frac{1}{2}$ ton	20.00	50.00
Tin ore, 80%, $\frac{1}{2}$ ton	500.00	550.00
Tungsten ore, 65%	425.00	450.00
Uranium ore, 10% min.	25.00	per unit
Vanadium ore, 15% V ₂ O ₅ , $\frac{1}{2}$ ton	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, $\frac{1}{2}$ ton	*15.00	20.00

Clay, domestic fire, sack, $\frac{1}{2}$ 100 lb	1.50	2.00
Cyanide, 98 to 100%, 100-lb. case, $\frac{1}{2}$ lb	0.18	0.22
Cyanide, 98 to 100%, 200-lb. case, $\frac{1}{2}$ lb	0.18	0.22
Cyanide, 129%, 100-lb. case, $\frac{1}{2}$ lb	0.22	0.25 $\frac{1}{2}$
Cyanide, 129%, 200-lb. case, $\frac{1}{2}$ lb	0.22	0.25
Lead acetate, brown, broken casks, $\frac{1}{2}$ 100 lb	9.00	10.50
Lead acetate, white, broken casks, $\frac{1}{2}$ 100 lb	10.50	10.75
Lead acetate, white, crystals, $\frac{1}{2}$ 100 lb	12.50	13.25
Lead, C. P., test, gran., $\frac{1}{2}$ 100 lb	13.00	15.00
Lead, C. P., sheet, $\frac{1}{2}$ 100 lb	15.00	18.00
Litharge, C. P., silver free, $\frac{1}{2}$ 100 lb	11.50	13.50
Litharge, com'l, $\frac{1}{2}$ 100 lb	8.00	9.50
Manganese ox., blk., dom. in bags, $\frac{1}{2}$ ton	20.00	25.00
Manganese ox., blk., Caucasian, in casks, $\frac{1}{2}$ ton	36.00	47.50
(85% MnO ₂ —15% Fe)		
Nitre, double ref'd, small cryst., bbl., $\frac{1}{2}$ 100 lb	7.00	8.00
Nitre, double ref'd, granular, bbl., $\frac{1}{2}$ 100 lb	6.50	7.50
Nitre, double ref'd, powdered, bbl., $\frac{1}{2}$ 100 lb	7.25	8.00
Potassium bicarbonate, cryst., $\frac{1}{2}$ 100 lb	12.00	15.00
Potassium carbonate, calcined, $\frac{1}{2}$ 100 lb	7.50	9.00
Potassium permanganate, drum, $\frac{1}{2}$ lb	0.10 $\frac{1}{2}$	0.13
Silica, powdered, bags, $\frac{1}{2}$ lb	0.03	0.06
Soda, carbonate (ash), bbl., $\frac{1}{2}$ 100 lb	1.50	1.75
Soda, bicarbonate, bbl., $\frac{1}{2}$ 100 lb	2.25	2.75
Soda, caustic, ground, 98%, bbl., $\frac{1}{2}$ 100 lb	3.00	3.25
Soda, caustic, solid, 98%, drums, $\frac{1}{2}$ 100 lb	2.50	2.75
Zinc shavings, 850 fine, bbl., $\frac{1}{2}$ 100 lb	12.00	13.00
Zinc sheet, No. 9—18 by 84, drum, $\frac{1}{2}$ 100 lb	10.20	11.00

Metalgesellschaft Statistics

The Metallbank und Metallurgische Gesellschaft of Frankfurt has recently published its annual volume of comparative statistics for the year 1912, which contains valuable information and tables giving the production of lead, copper, spelter, tin, aluminum, nickel, quicksilver, and silver. According to this report, the generally favorable conditions of trade and industry during the year 1912 caused a natural increase in the consumption of the metals, although a diminution in the demand was felt during the last quarter. The world's production of lead, copper, spelter, and tin for the years 1911 and 1912 was as follows:

	Metric tons		Increase in
	1911.	1912.	1912, %.
Lead	1,132,900	1,189,100	5.0
Copper	893,400	1,019,800	14.1
Spelter	902,100	977,900	8.4
Tin	118,700	123,100	3.7

Of this production the United States contributed 32.5% of the lead, 58.1% of the copper, and 32.2% of the spelter, being therefore the most important factor in the increased production of copper during the year. The consumption of these metals by the United States increased slightly over that of the previous year. The ratio of the consumption of this country to the world's output was 33.5% of the lead, 36.5% of the copper, 31.9% of the spelter, and 42% of the tin.

The new Underwood tariff will cause the average prices of the metals in the United States to correspond more closely with the prices in Europe. In previous years the differences in price have been very wide. For example, the price of lead in 1910 was 2.82c. per pound in London, while in New York the price was 4.446c.; and in 1911 the prices per pound in London and New York were 3.03c. and 4.42c., respectively. Under the Payne tariff the duties on the metals, computed on an ad valorem basis, taking the average prices for the year 1912, were about as follows: Aluminum, 43%; lead, 55%; nickel, 17%; spelter, 24%. According to the Underwood tariff, these duties will be reduced to about 25% and less, ad valorem, being 25% on lead, 15% on spelter, 10% on nickel, and approximately 15% on aluminum.

The amount of foreign ore smelted in the United States should be greatly augmented on account of the probable increase in the importation of ore from Mexico and Canada due to the lowering of the duties. This should be a stimulus to the lead and zinc smelting industries in this country.

The most notable increase in metal production in 1912 was in copper, the bulk of the increase being attributable to the United States, whose output of raw copper increased from 518,700 tons in 1911 to 592,400 tons in 1912. Most of this increase came from the porphyry properties of Arizona and New Mexico.

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Helmann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are f.o.b. San Francisco and subject to fluctuation. Other conditions govern Mexican and foreign business.

Company Reports

THE MEXICO MINES OF EL ORO, LTD.

The mines of the Company are at El Oro, state of Mexico, Mexico. The capital of the Company is £180,000

cost \$550.48. The general expense amounted to \$55,784.28 or \$0.35 per ton, and the taxes to \$73,012.34 or \$0.46 per ton. The total cost was \$653,287.28 or \$4.12 per ton. The all around recovery of the gross gold and silver contents of the ore treated was 88.99%, as compared with 87.30% in 1912. The ore in the lower levels is less amenable to treatment than the oxidized ore of the upper portions of the river and as a greater proportion of the ore will be coming from the lower levels, a slightly lower extraction must be

In 180,000 shares of £1 each. All are issued and fully paid. The report for the year ended June 30, 1913, gives the amount of ore mined during that time as 158,630 tons. The tonnage crushed in the mill was 158,395 tons. The average assay value of the ore was \$8.23 gold and \$3.61 silver. The bullion realized was \$1,200,519.02 gold, \$469,021.75 silver, a total of \$1.30 per ton, that of development \$130,453.81 or \$0.82 per ton, of milling \$34,692.12 or \$0.22 per ton, of cyaniding \$152,954.71 or \$0.97 per ton. The water supply

expected in future. During the year, four dividends have been paid, of 4s. per share, in all amounting to £162,000. The year shows a realized profit of £201,576 19s.6d.

THE MESABI IRON RANGE, in Minnesota, was opened in 1892, and yielded a production in that year of less than 30,000 tons. In 1894 it yielded nearly 2,000,000 tons; in 1902 it produced over 13,000,000 tons, or nearly half the total output of the Lake Superior iron ore.

Book Reviews

PROBLEMS IN PHYSICS. By Morton Masius. P. 23. Paper. P. Blakiston's Son & Co., Philadelphia. For sale by the *Mining and Scientific Press*. Price 10 cents.

This pamphlet contains 274 problems in physics which are based upon Duff's 'Text-book of Physics.' The purpose is to supply teachers with additional problems to those given in the book, allowing a wider range of selection for students' use. The publishers will supply the pamphlets gratis to all students using this text.

NEW ENGLAND AND NEW FRANCE. By James Douglas. P. 560. G. P. Putnam's Sons, New York. \$3 net.

Mining men may perhaps be unaware that Dr. Douglas, in addition to his achievements in the fields of business and engineer, is also known as an authority, of no mean rank, on the early history of New England and Canada. In an earlier volume he has treated at length of the influence of the French in the development of eastern Canada. The present volume deals with the French influence in New England, and is not intended to be a consecutive narrative of the history of New France, but is rather a comparison of the motives of the French settlers in Canada and the English settlers in New England and the effects produced by different methods of treatment of the Indians, of elementary education, the status of women, and the church in the two areas. Dr. Douglas' argument as to the causes which led the New Englanders into the founding of a nation through their failure to create a theocracy, while the French, with more influence over the natives and more energy for exploration, made but limited progress as the founders of a permanent colony, is of great interest. The average mining engineer has but little concern with colonial history, but he will find it productive of pleasure when put into such readable form as this.

MINE SURVEYING. By Edward B. Durham. P. 391. Index and Ill. McGraw-Hill Book Co., New York, 1913. For sale by the *Mining and Scientific Press*. Price \$3.50.

While the fundamental principles in surface and underground surveying are the same, the problems of mine surveying are not the same as those met with in the ordinary surface work, and as such a special study devoted to these problems is a valuable adjunct to mining literature. This latest work on the subject of mine surveying presupposes a general knowledge of survey methods, and the application of these principles to the special problems of mining is the purpose of the author. The scheme of treatment of each division of the subject is to outline the principles and general procedure such as an engineer familiar with the ordinary methods of survey would be conversant with and follow this with examples showing the variations in mining practice. The methods that are used for the overcoming of difficulties in the conduct of mine survey work are of special interest, and will serve as guides for the planning of work for special problems in mine surveying. The subject of mine surveying instruments is discussed with special reference to instruments peculiarly adapted to underground work. But few of the common instruments are shown, as they may be obtained from any maker and are fully described in catalogues. The modern tendency to represent mine models of three dimensions as an improvement over the mapping methods, which are more difficult to interpret by the layman, has led to the development of various types of models such as plaster models, plate models, and skeleton models. These types of models have been found well adapted to presenting an accurate figure of the character of a tract of land, the geological formation of a locality, or the plan of a mine. The building of such models is an interesting subject and is treated fully in this work. As both prospecting and development work are expensive, exploratory surveys have been found to greatly facilitate this work and reduce subsequent mining costs by reducing the amount of excavation to the minimum.

Recent Publications

ESTADISTICA MINERA DE CHILE EN 1910. The work of compiling these data was entrusted by the federal government to the Sociedad Nacional de Minera and completed under the direction of Don Guillermo Yunge, engineer of mines. P. 466. Maps. Santiago de Chile, 1913.

New Zealand government reports, Wellington, 1913:

MINES STATEMENT FOR 1912. Compiled by the officers of the Department of Mines. P. 158. Ill., maps, plans. This is the annual report covering statistics, reports relating to metalliferous mines and stone-quarries, state aid to mining, roads through goldfields, prospecting drills, water-races (ditches and flumes), schools of mines, inspection of mines, examinations for certificates (mine managers and mill superintendents), geological survey, state coal mines. The total value of all minerals produced during 1912 was worth \$14,500,000, a decrease compared with 1911, on account of several prolonged strikes in both islands. The gold output was 343,163 oz.; silver, 801,165 oz.; coal, 2,177,615 tons; kauri-gum, 7908 tons; and sundry minerals, 1729 tons.

REPORT OF THE ROYAL COMMISSION ON FORESTRY. P. 87. Ill., maps, plates. Gives details of investigations on the forest situation in New Zealand, and future proposals.

TWENTY-THIRD ANNUAL REPORT OF THE TRANSVAAL CHAMBER OF MINES FOR THE YEAR 1912. P. 480. Index. Johannesburg, South Africa, 1913. This volume is always of interest, and contains a considerable amount of valuable information on the mining industry responsible for a yield of gold worth £38,711,581 during the past year. The ore treated totaled 25,486,361 tons, and £8,291,477 was paid in dividends. The average number of employees was 23,817 whites and 192,575 natives, who received £6,962,690 and £5,962,997 in wages, respectively. Stores valued at £10,208,004 were purchased by all gold mining companies, and the Union of South Africa received a total of £2,305,689 as mining revenue from all mines. There were 5717 machine-drills at work, and the percentage of waste sorted from the ore was 12.57. The coal output was 4,751,850 tons; diamonds, 2,131,406 carats; silver, 1,018,253 oz.; copper ore, 1624 tons; and tin ore, 2948 tons. The report also contains the following matter: The annual meeting of the Chamber of Mines, and balance sheet, president's address, details of native labor, miners' phthisis, Sunday work, mining taxation, water supply, coal transport, statistical matter relating to the mining industry, exports from South Africa, legislation, and the annual report of the Witwatersrand Native Labour Association, Limited.

U. S. Geological Survey, Washington, 1913: Advance chapters from 'Mineral Resources of the United States, 1912':

GOLD AND SILVER IN 1912. By H. D. McCaskey. P. 55. The report contains valuable tables of the world's production of gold, as well as the statistics of the gold and silver production in the United States, and fairly detailed accounts of the production of the separate states.

PRECIOUS AND SEMI-PRECIOUS METALS IN CALIFORNIA AND OREGON. Mine Production. By Charles G. Yale. P. 90.

PRODUCTION OF COBALT, MOLYBDENUM, NICKEL, TANTALUM, TIN, TITANIUM, TUNGSTEN, URANIUM, AND VANADIUM. By Frank L. Hess. P. 77.

PRECIOUS AND SEMI-PRECIOUS METALS IN COLORADO. Mine Production. By Charles W. Henderson. P. 74.

THE PRODUCTION OF NATURAL GAS. By B. Hill. P. 61.

MINERAL RESOURCES OF ALASKA. Marble Resources of Ketchikan and Wrangell Districts. By E. F. Burchard. P. 77. Map. A fairly detailed account of resources that are likely to become important.

ZINC AND CADMIUM IN 1912. By C. E. Siebenthal. P. 53. Advance chapters from Bulletin No. 540:

PHOSPHATE DEPOSITS IN SOUTHWESTERN VIRGINIA. By George W. Stose. Bulletin No. 540-L. P. 16.

Pioneer Electric Locomotives in Alaska

What is claimed to be the first electric locomotives ever used in Alaska were placed in service within the past few months for mining operations by the Alaska Treadwell in connection with the readjustment of haulage incident to the opening of the new central hoisting shaft. The locomotives are used to haul ore in trains of 10 or more cars (80 tons) from the central hoisting to the various mills. The two initial electric locomotives are each of six-ton

ELECTRIC LOCOMOTIVE IN USE AT THE ALASKA TREADWELL MINE.

capacity and are operated on a 500-volt, direct-current circuit from an overhead trolley. They were manufactured by the General Electric Co. and are of the standard outside frame type, in which the side frames are placed outside of the wheels. Each machine is equipped with two type HM-801 motors having ball-bearing armatures. The motors are mounted in tandem, whereby one motor is placed in front of the rear axle and the other between the forward axle and the front end-frame.

The motors are of the usual series-wound type, and the controller is of the rheostatic, magnetic, blow-out type. A commutating switch is incorporated in the reverse cylinder, the handle of which has four 'on' positions, two for each direction of motion, one with the motors in series and the other with the motors in multiple. This system of control, by permitting the motors to be started in multiple, allows them to exert their maximum tractive effort independently, so that the slippage of one motor does not affect the other. With the series connections, economy in current consumption is effected while running, for the locomotive will then develop a given drawbar pull with one-half the current required with the motors in multiple, the speed, of course, being reduced in approximately the same ratio.

A New Drill

A small drill with automatically rotated bit is now being manufactured by the Hardsocg Wonder Drill Co. The drills use the ordinary seven-eighths and one-inch hexagon hollow steel and are operated in the same manner as an ordinary 'sinker,' except that it is unnecessary to rotate by hand. The rotation is accomplished by means of a ratchet following a long curved groove. The drills are in use in a Los Angeles quarry where, in soft rock, holes 2 to 6 ft. deep are drilled. Including changing of bits,

the maximum depth is accomplished in 14 minutes.

Graphite Brushes for Dynamos

For the convenience of users of Dixon's graphite brushes, the following is a summary of the conclusions deduced from tests and observations made by Albert F. Ganz, professor at the Stevens Institute of Technology: (1) Before

brushes are applied to a machine the commutator must be given a true and polished surface. A rough commutator will quickly wear away graphite brushes; (2) no oil, vaselin, or other lubricant should be used with brushes, but the commutator must be kept perfectly free and clean from such materials; (3) don't soak brushes in oil or grease; (4) when a new graphite brush is inserted on a commutator, its surface should be fitted to the surface of the commutator by means of finest sandpaper; (5) sandpaper the contact surfaces and commutator occasionally, as the bearing surfaces of the brushes will take on a high glaze in time and may cause squealing; (6) the brush holder should be so constructed that the entire contact surface of the brush is touching the commutator, and that the brush pressure is evenly distributed over the contact surface of the brush; (7) for slow-speed machines with little vibration the lower pressures will give satisfactory results, while for high-speed machines with considerable

vibration the high pressures must be used. The pressure should always be as light as possible. (8) Where two or more brushes are used in parallel on one machine, it is important that the brush pressure be the same for all brushes; and (9) motors require individual treatment, some require more petting than others. One must study conditions carefully and adjust brushes accordingly.

Commercial Paragraphs

The PACIFIC TANK & PIPE Co. has moved its San Francisco sales offices to its former offices, 318 Market street.

The ALBERGER PUMP & CONDENSER Co. announces that "on October 20, Frank E. Getts took charge as district sales manager of its Chicago office. At the time of his appointment to this position Mr. Getts was engineer in the Chicago office of the General Electric Co., and in connection with important steam turbine installations is well known throughout the United States."

ALLIS-CHALMERS MANUFACTURING Co. announces the removal of the sales and engineering offices of its mining machinery department from Chicago, Illinois, to the Milwaukee works at West Allis. The Chicago shops will also be removed to Milwaukee in the near future. The advantages to be gained by concentrating all departments, both commercial and manufacturing, at one plant are the reasons for this move.

The DORR CYANIDE MACHINERY Co. has opened an office at 50 Church street, New York, to handle its expanding business in metallurgical and industrial lines. The Dorr thickener is now being installed by the large copper companies quite extensively, both in connection with water concentration and flotation process. Mr. Dorr will spend a great deal of his time in New York this winter in connection with the Company's business and professional work.

The INTERNATIONAL MOTOR Co. makes the following announcement: Considerable publicity has been given to proceedings brought by George E. Blakeslee, a stockholder, to the extent of 187 shares of preferred stock, in which he asks for the appointment of a receiver and an injunction prohibiting the Company from borrowing other funds. His application for a receivership and permanent injunction has been dismissed by the court. Plans have been completed under which the existing or future merchandise creditors of the Company will have unusual protection for credit extended. With the exception of bills for merchandise, the Company will have practically no obligations to meet for the next three years, beyond its current requirements.

EDITORIAL

FROM Agra and Oudh comes the report that the short marriage season has had a discouraging effect upon the silver market. Are wedding bells of silver in the country east of Suez?

HANDLING flue-dust by mixing it with converter slag in a rotating cone is an ingenious method in use in the Southwest. It was described, as practised at Cananea in 1910, by Mr. Courtenay DeKalb in the *Mining and Scientific Press* for July 2 of that year. Details of the practice at Douglas are given this week in the article by Dr. James Douglas.

STUDENTS of fault phenomena should study the report of the 'Committee on the Nomenclature of Faults,' appearing in the *Bulletin* of the Geological Society of America, June 6. The committee, consisting of Messrs. H. F. Reid, W. M. Davis, A. C. Lawson, and F. L. Ransome, has prepared a comprehensive and well illustrated report, too long for reproduction here, and worthy of wide reading.

TUBE-MILL calculations are none too easy and there are many points upon which theoretical knowledge alone is not sufficient. We printed, October 11, a short summary of the principal calculations necessary, taken from an excellent general catalogue issued by the Cyanide Plant Supply Company of London. That catalogue, by the way, is a mine of technical information of high value.

IT is a pleasure to commend the frankness of Mr. D. E. Alves, chairman of the Venezuelan Oil Concessions Limited, who in his address before the annual meeting of the stockholders in London said: "I take this opportunity of informing the public generally, through the columns of the important financial organs, that until we have the results which the Company's engineers on the spot, and the management in London confidently believe will be achieved, the operations of this Company must be and are absolutely speculative." The Company has a concession covering 3000 square miles in Venezuela and, according to letters from the managing director who is on the ground, there are excellent indications of six oilfields. Gas has already been found, but expectations are not oil and at present, as Mr. Alves says, the business must be considered speculative. As one of the stockholders said, "if the chairmen of other companies would advise the public in the same way, I suppose we should hear of fewer scandals." Mr. Alves and his associates have set an excellent example and deserve the abundant success that we join in wishing them.

IN choosing between the mottoes, 'do your Christmas shopping early' and 'spugs,' we would cast our ballot with the former.

DECISION of the United States Supreme Court that a railroad company may not convey hay on its own line for the purpose of feeding its own mules used in the operation of its own mines without paying itself for the transportation of the hay, results in the Lackawanna railroad having to pay the Government for not paying itself.

HOISTING in balance results in economies, but also introduces problems. Some of these are brought out in connection with a description of the Balliet system of counterbalancing that we print this week. Unfortunately, considerations related to pending patents forbid printing at this time of drawings or details regarding the means adopted to accomplish the automatic increase of weight on the balancing rope.

PRIMARY and secondary are terms which have come to mean many things to students of ore deposits. Essentially they relate to order of deposition and give no clue to the source of the ore defined. None the less, 'secondary' ores are usually those which have been formed by downward leaching by surface waters of older orebodies. In places exactly similar orebodies have been formed by the same agencies, but where there were no older bodies to be leached; as in the case of the Leona Heights deposit discussed upon another page by Mr. A. R. Whitman. This nomenclature produced the absurdity of a 'secondary' orebody where there was no pre-existing primary ore. Mr. F. L. Ransome has proposed to meet this difficulty by introducing the term hypogene for the minerals formed by ascending hot solutions, and supergene for those deposited by generally downward moving and initially cold solutions. Presumably these terms are also to be applied to the deposits in which the minerals occur. Under this system it would be possible to define a supergene deposit that was primary or a hypogene deposit that was secondary.

ZINC metallurgy has been so frequently referred to as backward, that the statement has come to be accepted without question. On another page we present part of a vigorous defense of the art, written by Mr. George C. Stone, who as chief engineer for the New Jersey Zinc Company has had unequalled opportunities both for observation and experiment. Looking at the matter in a large way he makes a strong case for the retort system and he believes that progress is to be in the direction of still further improvement of the old Belgian furnace. Others think differently. At the Bully Hill mine in Shasta county, California, Mr. J. B. Keating and his staff are making zinc in a small way by a wet process and are steadily overcoming the difficulties met in increasing the scale of operations. Many others are busy upon wet processes and on electric furnaces, and the Continuous Zinc Furnace Company at Hartford, Connecticut, is obtaining surprising results from treatment of mixed ores in a furnace of new type. Improvement of both old and new types

is to be expected. For ourselves, we prefer the attitude of the optimist to that of the agnostic; the man who hopes for the best, rather than the man who does not know.

MINE examination in a far country and among a people strange to the engineer and perhaps strangers to mining, involves constant friction over little things. The geology and the mining problems involved may be simple enough, but the human equation must be taken into account, and in hundreds of small details there are potentialities of trouble. In the articles on 'Prospecting Conditions in Peru,' of which we print the first this week, Messrs. Charles S. Haley and C. A. Rodegerdts confine attention to these things. As members of the staff of Messrs. D'Arcy Weatherbe and N. B. Knox they saw several months' service in the mountains of Peru, and they have attempted to give that semi-technical information which they lacked at the beginning of the journey and would have found useful. Karl Baedeker established a great system of guide books, but it is in the letters of personal friends that we find mention of the little things that make or mar the pleasure as well as the success of a trip.

Federal Workmen's Compensation Law

The finding of the commission, which was appointed by an act of Congress passed on June 10, 1910, to investigate the subject of workmen's compensation, is such that favorable action upon the proposal to require interstate railroads to establish a system of compensation for accidents is likely to be taken by Congress. After numerous public hearings, at which all sides of the subject were debated, the consensus of opinion became that the old system of employer's liability has been outgrown, and that some form of accident compensation should take its place. The only differences of opinion were in respect to details. The fundamental principle that accidental injuries and death should be compensated as automatically as possible and that this compensation should be without regard to the cause of the accident, has been unanimously agreed upon. Statistics gathered by the commission show that the combined railways of the United States, during the years 1908, 1909, and 1910, paid for injuries to their employees and for death claims, either voluntarily or as the result of judgments, a total of \$10,085,000 per annum. Of this amount only about one-half reached the employees and their dependents; the balance being paid for legal and for other attendant expenses. Under the proposed compensation act, railway employees will receive approximately \$17,000,000 annually instead of the \$5,000,000 which at present is paid to them by the companies.

Under existing conditions the tendency is for the employee to exaggerate the employer's negligence, if any exists, in an effort to secure greater damages and for the employer to minimize his liability by a distortion of facts in the opposite direction. The result is that an unbiased statement of conditions is seldom brought out in the court room. With this condition of affairs removed it is believed that a coöperation between employer and employee will

result in a true report of working conditions and the number of accidents will be materially decreased. The passage of a bill along this line was recommended by the President in his recent message and will probably be considered by Congress during the present session.

While the law now proposed will affect railway employees only, it is generally conceded to be the first step toward accident compensation in all departments of industry. The success of such legislation is being attested to in various parts of the world and the project is generally believed to be past the experimental state. In England, Germany, and Australia, results have been most satisfactory to both men and companies. In England the average cost per miner amounts to \$5.35. In Germany every working man or woman regardless of nationality is insured against sickness, accident, invalidity, and old age, and during the twenty-five years since the system was established in Germany, it has proved an institution for the furtherance of the well-being of the working class, while under it employer and employees have been brought closer together in the promotion of mutual interest. In the United States, a number of the states have compensation acts. Even where not required by law, individual companies have in many instances established systems of automatic compensation for injuries and have found it most satisfactory to employer and employee. It brings workman and employers closer together and avoids the waste of time and money in litigation.

Geologists and Engineers Again

Complaint is made from time to time to the effect that geologists are prone to overlook the work of mining engineers when the latter trench upon their field. Recently Mr. T. A. Rickard brought up one instance falling within his own experience as a case in point, and last spring Mr. George Collins indulged in some gentle sarcasm apropos the subject and at the expense of the staff of the United States Geological Survey. Mr. J. F. Kemp replies this week to Mr. Rickard's request for information, and does so, as always, in excellent part. The merits of the particular case interest us little, but as one who has managed to make a living first as a professional geologist and later from mine management, and who is now outside both lines of work, we may be permitted to comment as an innocent bystander—even at the proverbial risk of attracting rocks from both sides.

There is, we are convinced, a wide-spread feeling that mining engineers do not get their just deserts at the hands of geologists; that their observations and statements of facts are absorbed without due credit; and that their suggestions as to structure and theory, based on long and careful work but expressed briefly and indifferently, are dismissed without consideration or are treated as lucky guesses. There is a distinct feeling among engineers that the geologist, by reason of facility in writing, reaps glory that in reality is due the engineer. We are convinced furthermore that there is just basis for this feeling and that in many instances the visiting geologist has quietly appropriated the intellectual property of the resident engineer. This is all the more resented since

each particular incident is petty and the engineer cannot claim his own without seeming to show an ungenerous and self-seeking spirit.

On the other hand, the geologists are unconscious of their fault, and even widely experienced men deny promptly that there is any such general sentiment as we have observed. We do not believe that geologists are less keen or less generous than other men, and the explanation lies in the difference in their training and mental attitude from that of engineer. The geologist is primarily a scientific investigator. To him, theories, from any source, are mere material for study. They have no validity, so far as he is concerned, until he has tested and proved them. This exposes him to the danger of assuming that nothing is discovered until he has found it out, but on the whole it is a sound and necessary mental attitude. A chance suggestion made by some one of his engineer friends may lead to sound or unsound conclusions; it is sure to lead to long and painstaking investigation if it be tested at all, and it is not unnatural that the investigator sees mainly the work that he did to establish the conclusion reached and forgets or minimizes the source of the suggestion. The engineer is not accustomed to the same methods of research. His main work and interest is concerned with other things, and, as is true of most men who work mainly in other lines and make few contributions to science, he is apt to overestimate such as he does make. There are mining engineers who are excellent geologists, but the majority are not, and some of the veriest geological nonsense we have ever read has been written by excellent engineers. The geologist sees this constantly and comes, perhaps unconsciously, to believe that as to geology a conclusion reached by a mining engineer must be tested before being accepted; and in the main he is right.

It is equally true that the geologist turned miner makes ridiculous mistakes and that the mining engineer has, and rightly, an equal distrust of his opinions on matters relating to the technology of mining and metallurgy. Here, too, there are exceptions, and some of the best mining engineers of our acquaintance were first trained as geologists. The rule, however, holds true, that the work of the two is distinct and that one attempting to cover both fields may rightly be held to high standards.

With this mental attitude on both sides, it is not surprising that friction and soreness occasionally develop. A further cause of misunderstanding lies in the fact that engineers and geologists do not read the same periodicals except in part. A geologist taking up a new problem and reviewing the literature as a first step, must go through a whole series of journals that few mining engineers ever see. It is not surprising that he does not comb with equal care those whose columns are devoted mainly to engineering. He ought to do so, but he does not. The men of the two professions have much in common and the world around they are the best of comrades. We believe that each will gain by cultivating the other. If the engineer will test his geological theories a bit more carefully and write of them somewhat more fully, we believe the geologist can be brought to make the fuller acknowledgment for which any circumstance calls.

Prospecting Conditions in Peru

By CHARLES S. HALEY and C. A. RODEGERDTS

From the days of Magellan and Pizarro, that part of the Andean region comprising the northern half of Chile, the western half of Bolivia, and almost all of Peru, has been fraught with much interest to civilized humanity, because of its great mineral wealth. Spanish galleons, laden with the historical 'pieces of eight', continually furrowed the oceans with their treasure-laden hulls, and the whole history of the terrible struggle between England and Spain for the mastery of the sea is inextricably bound up and intertwined with the history of the production of the precious metals from the fabled exhaustless treasure-stores of the Incas.

The days of Sir Francis Drake and Sir Henry Morgan have long been memories of the past. The buccaneer and the 'gentleman adventurer' have made

government has built and subsidized one of the most important lines; an English company is backing two others, one is operated under a Spanish name called the Chilean line, or *Compania Sud-Americana de Vapores*; and another known as the Pacific Steam Navigation Company. Of the three lines, running as far south as Callao, the Chilean line is perhaps the best operated and most comfortable; from Callao south, the Pacific Steam Navigation Company maintains a service which is excellent. In the last few months, however, W. R. Grace & Company has put on a magnificent line of steamers which make the trip from New York to Seattle by way of the Horn. Aside from these lines, the Kosmos (primarily a line of freighters), is said to run some comfortable little steamers, though more or less irregularly.

ENGINEERS' CAMP IN PERU.

their bow and passed into the wings. The "pieces of eight" are one with the "fifteen men on the dead man's chest," in the hold on the memories of our boyhood. And yet, quietly and unostentatiously, in the shelter and protection of modern civilization and law; with the aid of all the vast resource of modern mechanical skill, this same territory is again being exploited, and attention is again being turned toward this latest of earth's treasure-houses.

It is the purpose of this article to give an idea of the conditions which are to be found in Peru today, by any one engaged in the examination of mining property, and from this to reflect, as far as possible, some idea of the conditions for subsequent working of property after it has been acquired.

Relation of Peru to Latin-America

Peru is taken as the subject, because general conditions in that country are typical of practically all of this region in which so much interest is now being taken. As a matter of fact, the position of Peru among her Latin-American neighbors is potentially superior to all of them, with the exception of Brazil; but actually, Peru has just begun to take advantage of her own. Development of transportation facilities is at present her most crying need and the exploitation of her mineral wealth will follow swiftly upon its heels.

As everybody knows, Peru is accessible on the Pacific Coast by steamers from Panama. The Peruvian

The Voyage to Peru

The voyage is ordinarily smooth and pleasant, from Panama down to Callao. It is supposed to take from six to seven days, and usually does. The principal ports of call on the way down are Eten, Paita, Pacasmayo, and Trujillo. A good deal of freight is usually taken on at these points, chiefly consisting of sugar, hides, rice, wool, and even cotton. Most of this is transshipped for England and the Continent, though a certain amount of it is kept for local use.

From the appearance of the country along the coast (which is not visible during the first two days of the voyage from Panama, as far as Eten, at the extreme north of Peru), one wonders where all this produce is grown. Barren, dry, and wave beaten, the low cliffs, for the most part sandstone, look as if guarding an absolutely barren and desolate land. Once in the interior, however, and traveling up the streams, this is readily explained, and the wonderful fertility of this soil where supplied with water from the rivers (for this is an absolutely rainless belt), is well demonstrated.

After leaving Trujillo, the course of the steamers again leaves the coast, until the broad harbor of Callao swings into view. The first thing the traveler will notice about Callao is the mosquito fleet of *fleteros*. As the big steamers do not discharge passengers at the docks, their passengers and baggage are left to the tender mercies of a swarm of smiling pirates who compete with one another along the decks of the ship for the disembarking passengers. Having picked out the most promising, and, if he is wise, having carefully arranged details of price beforehand, the traveler will disembark from the ship's ladder into a rowboat, with such hand grips, or *maletas* as are convenient, and allow himself to be freighted to the pier. By previous agreement, all grips and trunks will be delivered at whatever hotel may be desired, either in Callao or Lima, but the traveler must be prepared to first escort them through the custom house.

At Callao, as at all ports of Peru, this institution

is not very prepossessing in appearance. A long, low, wooden shed, filled with perspiring officials and assistant officials with their assistants, a sprinkling of soldiers, and a motley crowd of *fleteros* on guard for fear that their patrons may get away with their luggage unawares, makes the position of the traveler, especially of the gentler sex, not the most enviable thing in the world. The inspection of luggage is, for the most part, rather thorough. One of the first things to startle the incoming traveler, however, is the enormous duty on personal effects, such as kodaks, typewriters, or revolvers. These articles, no matter what the intent of the user as to retaining them personally may be, are subject to duties from 25% of their value to as much as they are worth.

Duties on Machinery

Furthermore, in case of importing mining or industrial machinery, rather anomalous conditions exist at different ports. All mining machinery is supposed to go in free, when it is to be used for the development of a particular mine in the country, or to prospect it. Yet, at the port of Mollendo I know of an attempt to hold a man up for twelve hundred dollars in duties, which was only thwarted by a direct appeal to the authorities in Lima, through influential friends. During the recent rush to Bolivia, many of the American miners who brought machinery for prospecting purposes through Mollendo as the port of entry, complained bitterly of having to pay the Peruvian government duties on goods in transit to another country, when, as a matter of fact, it appears to have been plain and simple graft.

The traveler and his goods having safely landed at Callao, will probably take the electric road to Lima, although there is a regular local train service at about hourly intervals through the day. There are few hotels worthy of the name in Callao, whereas in Lima, twenty-five miles away, there are good hotels and restaurants. Nothing, of course, to be compared to the average city hostelry in this country, but nevertheless, fairly comfortable and clean. There are a few comfortable little clubs whose hospitality, to a visitor, is very acceptable.

After disposing of the attempts to overcharge on the part of the *fleteros*, and getting his luggage comfortably settled about him, the visiting engineer will probably want to get his bearings and see his bankers. While there are street railways in Lima, the principal means of travel for the better classes consist of little victorias drawn by one or two shaggy little ponies. The usual tariff for these vehicles is twenty centavos (ten cents gold) for any journey within the city limits. This means between stopping places, and an extra fare is charged for every stop. For communication with any of the surrounding suburbs and watering-places of Lima, such as Chorrillos, Barranca, and Miraflores, there is a line of electric coaches.

Then comes the problem of getting one's mail.

So long as this has been sent in care of one of the leading merchantile or banking houses, there will not be much trouble about getting it; but if merely sent in one's own name, care of general delivery, you may be given all the personal assurance possible that there is nothing for you, and then drop in a day or two later and see a letter advertised on the bulletin board with your name. This difficulty increases as one goes into the less settled regions in the country until it becomes a rather serious problem. The best solution is to have all mail sent in care of one of the two or three leading English or American merchantile houses, and retained until your arrival in one of the larger cities. By this means, though delay may be occasioned, you are sure eventually of receiving your mail; otherwise you are taking chances.

In the case of outfitting a prospecting expedition, aside from the main essentials, such as machinery, instruments, etc., the main details may be safely left to be completed at Lima, or in the south at Are-

SAN PEDRO, ONE OF THE CITIES ON THE ROUTE.

quipa. Tents, bedding, etc., are apt to be of a better quality and cheaper if brought with one. All the food supplies, tinned goods, hardware, and even minor pieces of machinery, can readily be obtained in Lima. One exception that comes to mind is that of a stove, however. A portable camp stove was not to be found in Lima a year ago.

Prospecting Equipment

In the case of minor prospecting equipment, however, such as rockers, portable sluices, etc., carpenters and sheet-metal workers, as well as blacksmiths, can be found to make them at reasonable prices, in Lima, Callao, and Arequipa. Such work as one might expect to have done in a small country town in the States can readily be depended upon here.

Food supplies are cheap, due, of course, to water transportation and cheap markets. By the time, however, that one has delivered them in the more out-of-the-way parts of the country, their original cost will probably be lost sight of. This is due to the lack of railroad facilities.

Callao and Lima are the entries for the Cerro de Paseo Mining Company, and a railroad scrambles up the mountains behind the city to an altitude of 17,000 feet. A road to Huancaya runs off in a southeasterly direction from Lima, without any apparent

purpose in life. In the south, a road from Mollendo, on the coast, connects with Arequipa, the second largest city of Peru. From Arequipa this road goes northeast to Juliaca, not far from Lake Titicaca and the Bolivian line. At Juliaca is a junction between the rail and steamer line running to La Paz, Bolivia, and a narrow-gauge railroad running north and slightly west to Cuzco, the ancient Inca capital of the country. This road extends through the heart of Peru, reaching toward Lima, whence the aforementioned road to Huancaya stretches out to meet it. The junction between the two, however, will necessitate the traversing of a rough wild country. The intention is to connect them, however, at some time in the future, as the road is not only a necessity, but will open up one of the wealthiest river-valleys from an agricultural standpoint in Peru, that of the Pachachaca. As at present planned, this road, passing through Ayacucho and Abancay, and connecting with Cuzco, will greatly facilitate the transportation problem, which is one of the greatest drawbacks to the development of the mineral wealth of Peru. When this road is constructed, spurs and connections can be built to serve the major portion of the mineral and agricultural country of the south. As stated, the government is planning this road, but funds are not available at present to build it, so how soon it will actually be under construction is largely a matter of conjecture.

Aside from the roads mentioned, there are a few short railways connecting the coast with points on the interior, but the main and dominant factors in the transportation remain, as of old, the mule and the llama. The latter shall be treated again at greater length.

Food Supplies and Minor Equipment

The minor items of an outfit, such as tinned goods, coffee, etc., it is possible to buy at reasonable prices at Lomas, Chala, or Mollendo, all coast ports. Arequipa, the largest city of southern Peru, is a good outfitting point, served through Mollendo, and practically all supplies can be bought there as cheaply as in Lima. Cuzco can be depended upon for food supplies, leather goods, and blankets.

Assuming as an average case, that the prospecting or examining party expects to go inland from one of the coast ports mentioned, and that the outfit has been all assembled, the next and most important question is the mule train for transportation of the outfit. The pack-saddles and riding saddles can be obtained in Lima, provided that the engineer decides that he wants to buy his mules and complete outfit. This, however, we should strongly advise against, unless it is expected that permanent use is to be made of the outfit. In the latter case, however, it will be well to give a short statement of conditions to be encountered.

In the first place, if you can obtain a trustworthy purchasing agent in one of the smaller coast ports, you are lucky. I will assume that you are not. You may have every assurance that your man is looking out for your interests—but—wait till the bill comes in. It is, of course, best to go immediately to the ground yourself, and hurry matters as much as possible, for if you try to do anything at long distance

in the country you will have an experience with the *manana* proclivities of the people which will wear out your patience. Once on the ground, and possessing a moderately good knowledge of the language (which with reasonable application, can be acquired in two months or less), you have some chance of getting things done.

On the coast, good riding mules are quoted at prices ranging from £25 to £30 apiece. Pack mules cost ordinarily less; from £15 to £18. In this connection, it should be mentioned that the Peruvian monetary unit is the English pound, divided decimally into ten soles (the sol is about the size and weight of a silver dollar, and worth about forty-nine cents), which are again divided into centavos, or hundredths. There are also five-sol pieces, of gold, valued at ten shillings, English money.

Pack Animals

In the interior, mules cost much less. Mules are offered at £10 each in Sandia which at Lomas, on the coast, and to the north, would have cost twice that sum. Further, and this is a very important point, the coast mules do not do well in the altitudes, being unused to the rarefied atmosphere. For this reason, it is unwise to load more than two hundred pounds per mule; and even with the mountain-bred mules, this load is not usually exceeded. To one who has handled mules in the western country of the United States and seen them carrying three or four hundred pounds over the rockiest trails, this seems ridiculous; but it is none the less a fact. Although appearing as large and strong as American mules, they simply lack the stamina. Further, the style of packsaddle that is used by the Peruvian *arriero* is, in its very nature, a mule-killer. It is a treeless saddle, consisting mainly of a pad, surmounted by a cinch, with sheepskins and blankets distributed in fearful and wonderful fashion underneath and above. You may have bought your saddles in Lima, with full assurance that you have bought the only suitable thing, and have paid a price that opened your eyes, considering the price of a cross-tree saddle such as is used in other countries. However, your chief *arriero* will assure you that they are absolutely unfitted for your needs, and use the saddles to excuse his own inefficiency in handling the loads.

Nevertheless, where two white or half-breed Indian packers in the States, with the aid of a bell-boy, will handle a string of thirty mules, a string of half that size in Peru will necessitate about one man to every two mules. Of course, the wage cost is much less, but the delay and aggravation of having your packs slip over to one side, every hundred yards of the journey, and the consequent damage to the backs of your animals, as well as to the contents of the packs themselves, are things that would take a good deal of money to compensate.

Native Labor

In this, as in all things, to one trained in the gospel of efficiency, with the belief ingrained in his heart that all things should be done well and as speedily as possible, or else there is no excuse for doing them, lies the greatest difficulty of work in Latin-American countries. A man will wear himself out

in working against the inertia of the whole country, and trying to accomplish something. Only a young man, or one in full possession of the best of his physical and mental powers, can stand the constant irritation, and he must school himself to an abnormal patience, though in no whit yielding the fight.

As to the *arrieros* themselves, many of the same conditions applying to the mules will be found applicable to them. On and near the coast, they are mostly of a mixed Indian breed, speaking a sort of Spanish. They will readily chaperon a string of mules as far as seventy-five or a hundred miles into the interior, but beyond that they are extremely reluctant to go, and it is advisable to change to the mountain drivers, who are practically pure Indian, and who, in their turn, do not much care to go down to the coast. On the whole, the mountain Indian, who speaks scarcely any Spanish, if at all, is more faithful, and a better attendant to the needs of his charges, than his more highly educated brother of the coast.

Freight Contracts

This matter of the care of one's mules is one of the principal reasons for contracting freight. If the head *arriero* does not have to be responsible to the owner of his mules (and, in the case of a foreign engineer, such responsibility is *nil*), it is almost a certainty that he will ruin them. Careless, slipshod packing, poor feed, and careless shoeing will soon reduce the best string of mules procurable to a pitiable state of suffering. As the usual cure for saddle galls seems to be thrusting a lance into them until the animal becomes weak from loss of blood, it is advisable not to get more saddle galls than you can help. And if you take positive measures to insure proper care of your own mules, you will have to do it with your own hands, while the members of your *arriero* gang are sitting around watching you, with the resulting maddening delay in the journey; for unless you are in a position to drive things along all the time, you will get nowhere.

So much for private ownership of mule trains. Most of these evils can be avoided by contracting your mules, both for freight and riding purposes. In the first place, your *arrieros* live in fear of the *patron* who employs them, and who owns the mules. He naturally wishes the trip made in as quick time as possible, and at the same time is in a position to insist on proper care of his beasts—this last, of course, from utilitarian rather than humanitarian motives, because he is in the contracting business, and realizes the value of his stock, and the benefit of getting as much work out of them as possible before they are worn out.

As a rule, the contractor knows the routes well, and practically all the strain of conducting a journey in a strange country is taken off your shoulders. This amounts to a good deal, at times, for if your guides are inefficient, you may have to go for thirty-six hours without water or suffer some other inconvenience. No assurance is to be had that your guides are efficient, unless you contract for them.

Most important of all, you are spared the private graft which must always be faced by the foreigner in transaction of any buying and selling. This you can-

not get around, and it is useless to expect to avoid it. The main problem is to reduce it to a minimum. No one objects to paying a reasonable commission for time and labor involved in purchasing mules, for instance, but when this commission amounts to more than the original purchase price of the animals, it becomes an imposition.

Of course, as stated, if a long stay is contemplated, as in the development of a mine, it may be advisable to purchase your own pack-train. Under these conditions, it is advisable to import a good packer to take charge of the train, to use cross-tree saddles, and to establish a regular route of rest and feed stations. Some of the larger mines have done this, and run their pack-trains after the American style.

Assuming, however, that you are merely making an examination, and wish to contract, it is well to quote some of the prices which you will have to pay. From almost any of the coast points mentioned, it will cost you about six dollars gold per mule load of two hundred pounds, per hundred miles. In heavy packing, the contractor is apt to be overcareful of his mules, and reduce the load if possible. For instance, the limit on packing an Empire drill, with four inch casing, is two sections per mule, according to one contractor of Sañaica, in the province of Aymares! At this rate, it would require about ten mules for one drill and sixty feet of pipe. They can usually be rendered more optimistic in their estimates by competition, however.

In the southern portion of Peru, in the provinces of Sandia, Carabaya, and Cuzco, the llama is often used in competition with the mule. For instance, the Inca Mining Company with a wagon road a hundred miles in length, reaching from Tirapata northward, can use carts and wagons for freighting, and then transfer to muleback for distribution purposes. Nevertheless, to deliver goods in Sandia, about a hundred miles from the railroad, costs about five soles a hundred weight. On the other hand, the llama, because of his lower standard of living, being able to pick up his food by the wayside like a sheep, can deliver for about four soles in the same place. On level ground, such as the pampas, llamas can carry as much as a hundred and twenty-five pounds; but in the rougher hill country, they are limited to about fifty pounds. Their use is not confined to any one portion of the country; they are the Peruvian national beast of burden. They cannot be hurried out of a walk, and it is rather amusing to watch them striding sedately by. Their flesh is sometimes used for food, but it is coarse and often tainted with disease.

Native Porters

Competing with the mule and the llama, one sometimes sees the peon himself. For instance, in carrying a pulling-post for an Empire (and it may often be necessary to do this for a hundred miles, so scarce is the timber in places), a gang of Indians is about the best available means, especially if the trails are steep and tortuous. On one occasion, an Indian was hired to carry a five-gallon can of coal oil a distance of twenty miles, for twenty cents; and he seemed well satisfied with his pay.

To return to the expedition, about to leave the

coast region, and ascend into the mountains, at all postoffices, *tiendas*, and other places, where one has to transact business, near the coast, Spanish is fairly well understood. As the mountains are reached, however, this can no longer be said. In fact, if contemplating doing much business with the natives or even hiring a gang of them to work, it is well to learn a little of the Quichua dialect. This is very easy, as the forms and grammar are quite regular. The pronunciation is a little troublesome, as one peculiarity of the language is that double and even triple consonants occur with frequency. However, a couple of hundred words will suffice for all ordinary purposes.

Use of Coco Leaves

Also, among the Indians of the mountains, it is well to use a good supply of coco leaves. This is a bitter plant, grown in considerable quantity in some districts and dried. Its use seems to be an inveterate habit among these people, and they chew it incessantly. Every man, woman, and child among them will have his little leather pouch, and will trudge contentedly along all day, chewing ruminatively on a cud of the stuff.

The usual method of access to the mountains is, of course, through the river valleys. In the immediate vicinity of these rivers the fertility of the soil is evidenced by luxuriant growths of cane, while outside of the limits of irrigation, the ground will be barren and desolate. The rivers themselves are very small during the greater part of the year, and usually run underground before reaching the ocean. As a result, there are no fertile deltas visible along the coast. On one side and another of the main river valley, are dry *quebradas*, reaching to the towering mountains on either side. The trail ascends from the river basin, and eventually will follow one of these dry and rockstrewn *quebradas* and straight up the side into the mountains.

The evidence of sudden torrents is plain. Great boulders of many tons of weight lie in the dried up channels, and the courses are torn and scarred. The general dryness of the country, by contrast with the river valley just left, becomes oppressive. Finally, winding steeply up the scarred and jagged shoulder of the mountain, you come out upon a bench of almost level ground. Before you, and more forbidding than ever, in the wearied state of yourself and your animals, rises another terrace, towering two thousand feet above you.

The Approach to the Cordillera

In the course of two days of this sort of travel you may climb ten thousand feet or more. Suddenly the character of the country changes. Still dry, but no longer forbidding, it stretches away from your feet, in the undulating ground of the pampas, and you realize that you are at last on the roof of the world; but not quite on the ridgepole. Far away to the east rise the snow-capped peaks of the Cordillera, towering up a good five thousand feet higher, and reminding you that yet another barrier must be surmounted if you would gaze down the eastern slope into Bolivia and Brazil.

Here you notice a marked change in climatic conditions. Before this, you have been in an absolutely

rainless country. Now, riding along the edge of the pampas, you look down for two or three thousand feet into broad valleys and plateaus which bear all the marks of irrigation and cultivation, although exceedingly patchy and spotty. It is from the cultivators of these little green spots that you will draw your labor later on.

Here are the towns of San Pedro and Pulquio, on opposing flanks of the Andes, with a broad valley some ten miles in extent between them. Like clinging fragments of a last year's swallows' nest, the mud and stone built houses flank the steep and narrow streets. Extending down from the towns, and out across the valley, stretch the long, interminable wavering stone fences so characteristic of this country. What may have been the purpose of these irregular quadrangles originally, in the days of the Inca, is beyond power to guess. At present, so dry and barren are many of the patches of ground that they enclose, that one assumes the fences are there to keep anything living from getting on the ground and starving to death.

Leaving this valley, and climbing higher, you come out on another bench of the pampas, at an altitude of about fourteen or fifteen thousand feet. If your heart is weak, you may at this time be suffering from *saracho*, the dread 'fever' of the Andes. Many, however, remain absolutely unaffected. Beyond a very quick-coming fatigue attendant upon exercise, and at times a shortage of breath, it may be that no other effect will be noticed. After a few weeks' residence, even this will pass off, and one can walk many miles at fifteen or sixteen thousand feet elevation, without the least after-effect.

Population

As the pampas are ascended, the villages become fewer, farther apart, and scantier. At this altitude, during the summer season (which comes in the months of December, January, and February), there are apt to be frequent rain and hail storms. Owing to the abrupt slopes and lack of vegetation in the country, the water runs off directly into deep gorges of the mountain torrents. As a result, coarse grass such as a sheep alone may thrive on, and a brush somewhat similar to our sage-brush, is about the only vegetation that abounds. There are practically no trees of any size in the country, though there is an occasional scrubby type, somewhat similar to the buckeye, which clings closely to the watercourses. These latter streams are more abundant, as you near the Cordillera, where their source, the snow, is continually feeding them, and the pasturage becomes better. As a matter of course, the inhabitants of this region are shepherds, totally ignorant of Spanish, and extremely peaceable and meek. There are some few cattle ranging here, but your meat diet is confined almost solely to mutton. Old men, old women, and children do most of the shepherding, and occasionally shear a little wool, which is wound into thread on hand spindles, and woven on hand looms into the inevitable poncho. One poncho serves the average peon for from ten to twenty years, and is then worn to fragments by his children. As their only other need is an occasional handful of maize, raised in abundance on the river bottoms, naturally

the question of currency is of little importance to them, save as a solution of the liquor problem. For every specimen of the Quichua race—man, woman, and child—appears to be an alcohol drinker. In reading an account of the various imports and exports of Sandia province for one year, it is to be noted that the value of alcohol imported amounts to one-third of the total exports of the province. In other words, all the surplus above living expense. The houses of these pampas-dwelling people are, for the most part little circular walls of stone, topped with a thatch of the longer, coarser pampas grass.

Crossing the Cordilleras, a different type of country is entered. There is much more evidence of rainfall, and in the summer the rains are daily. Little shallow lakes abound and great herds of sheep and llamas, as well as alpacas, are grazing over the flats. Often one rides along the shores of a mountain lake for a mile or two, and the surface is spotted with wild ducks and geese, called *guachos*.

The Eastern Slope

Suddenly one comes to a break in the pampas. Down below, stretching for thousands of feet, lie the brown flanks of the mountain sides, and, invisible at five thousand feet lower elevation, flows one of the headwaters of the Amazon. Along the banks and benches above the river, stretching up into the well watered *quebradas* on either side, are little patches of alfalfa and maize, which are the main support of the countryside. At intervals along the river banks little terra-cotta colored villages appear, each with its chapel and bell tower standing guard over the community. From these villages are supplied the main body of laborers upon whom you will have to depend. Many of these speak quite a little Spanish. If it were not for the desire to buy alcohol, there would be practically no incentive for them to bend their backs to the service of the strange desires of the white men.

Here again comes a temperamental clash. It will be supposed that the neighborhood of one of these little towns is the goal of your journey, and that you contemplate a two or three months residence here while examining a large alluvial or quartz property. You are naturally anxious to get to work at once, and go down to the village to see about labor and food supplies. You will probably make the acquaintance of the mayor of the town, and the principal storekeepers. These men are naturally interested in the employment of the men of their village, because it means that they will eventually get the money paid in wages. In many cases they have a hold on the peons, who may have run in debt to them. If you contract for men from them, you will be much surer of your labor supply, although you will be expected to allow the *patron* to make a profit on each man's labor, running from twenty to fifty per cent. Even in doing this way, you will probably be disgusted by the dilatory fashion in which your labor is furnished. However, if you do not do it, you will often find yourself utterly without men, in spite of your best efforts. The Indian simply does not need money, because his standard of living is so low. He will contract to work for a week at a time, and

when his week is up, you may depend upon it that you will not see him again for some time. If, however, the principal men of the village have a financial interest in supplying you with labor, you will find the supply much more regular.

The attitude of the average Peruvian toward the Quechua is well expressed by the remark of a young Limanian friend of mine, who said, "*Esos no son Peruanos; no mas Peruanos que las llamas.*" (Those are not Peruvians; no more Peruvians than the llamas.) The price of labor per diem is very cheap in most parts of Peru, varying from twenty cents gold in the central provinces to one dollar gold in the quartz mines of the south. The cheaper the labor is, however, the more costly it seems to be, looking at it from the standpoint of work accomplished. I have found the average Indian of the south to be worth much more per day than his less-paid brother of the north and central portions of the country. One who is used to handling intelligent white labor on the theory that it is cheaper to discharge a man than to waste your time watching him, finds a different condition here. On that theory, it would be necessary to discharge all of your men faster than you could hire them.

(To Be Continued.)

Electrolysis of Aqueous Solutions of the Simple Alkaline Cyanides

According to G. Howell Clevenger and Mortimer L. Hall, the following conclusions were arrived at after considerable experimenting and presented at the twenty-fourth general meeting of the American Electrochemical Society at Denver, Colorado: (1) The bulk of the decomposition of cyanide occurring during electrolysis is due to oxygen liberated at the anode through the decomposition of water. (2) The principal final reaction in solutions of cyanide containing protective alkalinity, which in cyanide mill practice is usually due to lime, is the formation of the corresponding alkali carbonate. This accounts for the formation of large amounts of calcium carbonate during the electrolytic precipitation of gold and silver from cyanide solutions. (3) A consideration of the reactions previously discussed will explain the failure in many cases to obtain regeneration of cyanide when such regeneration is theoretically possible. It is apparent that the decomposition of cyanide may easily be equal to or greater than that regenerated through the precipitation of the metal in solution. (4) The Liebig titration for the estimation of cyanide in an electrolyzed solution gives results which are low. (5) The changes taking place in fresh and electrolyzed cyanide solutions, upon standing, are different. (6) While not wishing to discourage investigators working along the lines of aiding extraction with refractory ores by electrolysis, it is of importance to call attention to the disadvantages which may arise through the indiscriminate use of electrolysis with an ore pulp. First, a large loss of cyanide may result from which there is no benefit derived, and, second, electrolysis may actually interfere with extraction through the formation of a coating of calcium carbonate upon the ore particles.

Synthesis of Pyrite

ALFRED R. WHITMAN

*Economic geologists have been debating whether certain deposits of pyritic copper ore could have originated through the re-deposition of pyrite leached by meteoric waters from overlying rock. But in the experiment here described pyrite was actually re-deposited from meteoric waters which had leached it from overlying rock, in the laboratory. Therefore the potency of the process to perform the function of creating a deposit of pyrite, can no longer be doubted.

The type of copper deposit referred to is that which produces the pyritic copper ores of Shasta county and the pyrite of Leona Heights in Alameda county, California. These deposits are large solid masses of pyrite containing copper, enclosed in a country rock of rhyolite or andesite. The sulphide masses are not crustified, nor do they necessarily lie along faults, but they are apparently isolated in most cases from any connection with possible channels of ascent for deep seated mineral-bearing solutions, and are devoid of evidence of foundation in subterranean chambers. If they have originated through magmatic segregation in intrusive bodies, the mode and evidence of segregation are very obscure; but at Leona Heights, at least, the enclosing rock is a series of lava flows, a fact which precludes the possibility of such an origin.

Origin of Leona Heights Deposits

The only reasonable mode of origin remaining for the Leona Heights deposits, is that of deposition from waters descending from the surface. In the case of the Shasta county deposits, the idea has been proposed that descending surface waters oxidized the primary pyrite grains, disseminated through the country rock, and carried the resulting sulphate in solution to, or near, the ground water level, where, in a reducing environment, the sulphate was transformed back into a sulphide, replacing the country rock, and giving rise, by slow accretion about a central core, to the large solid bodies now being mined. I examined the pyrite deposit at Leona Heights, owned by the Leona Chemical Co., and formed the same conception of its origin. From a detailed study of this body, it appeared that the pyrite deposit had grown by accretion, and had replaced the enclosing rock as it grew, the rock being changed to kaolin and amorphous silica immediately before being replaced by the pyrite. The process had evidently been brought about by solutions, and since acid solutions are generally understood to be the chief agents of kaolinization, it was assumed that some reaction of sulphate solutions had taken place at the growing points of the orebody to liberate the sulphuric acid which must have produced the kaolin from the feldspars of the rock.

With the hope of clearing up these obscure points of geochemistry or of at least circumscribing them within the limits of laboratory research, the follow-

ing synthetic experiment was undertaken toward the end of last year. A zone of leaching corresponding to the region above ground water level, was constructed. Below this, there was placed a zone of reduction, corresponding to the region below ground water level. And two water solutions, corresponding approximately to two types of surface water, were allowed to percolate downward through both zones. The zone of leaching consisted in two co-ordinated sets of five vertical glass tubes, $1\frac{1}{4}$ inches in diameter, and from 2 to 4 ft. long, filled with crushed andesite, with pyrite and chalcopyrite artificially disseminated through them. One set of tubes received one surface water, and the second set the other, the solutions flowing from one tube to another through each series. Half of each system was electrically heated to 45°C . in an asbestos-lined wooden box. From this zone the solutions flowed through small glass tubes into four vertical larger tubes filled with reducing agents, carbonaceous in two of the tubes and mineral in two. After passing through this portion of the reducing zone, the solutions passed in two cases, directly into carboys, and in the two other cases through horizontal tubes half filled with kaolin, and then into the same carboys. The solutions flowing through the kaolin tubes had previously passed through the heating box in the upper zone. Solutions of humus acid were introduced into the carboys in small quantities to assist in producing reducing conditions there. The carboys also contained mineral and carbonaceous reducers and kaolin. The rate of flow through these systems was fairly constant, averaging one drop per minute.

About one month after the experiment was started a green slime began to accumulate around the grains of sulphide in the zone of leaching, showing that the process of conversion of sulphide into sulphate was in progress. Gradually more of this green sulphate appeared in this zone, then in the tubes leading to the lower zone, and finally at the bottom of one of the reduction tubes. This indicated that the iron sulphate was being transported through the zone of reduction. About a month later, a black discoloration was observed in the kaolin of the kaolin tubes. From day to day this black discoloration spread, and increased in intensity until solid black masses had formed, imbedded in the kaolin.

Result of Synthetic Experiment

In the sixth month from its inception, the experiment was dismantled. No sulphide precipitate was found until the kaolin tubes were examined. Then it was discovered that the black substance was powdery pyrite, and that the black masses within the kaolin were clusters of cubic crystals of pyrite. Small pyrite cubes were also found disseminated through the kaolin. This pyrite had been precipitated from the solutions and proved that cold, dilute water solutions could oxidize and transport pyrite, and that sluiced kaolin could precipitate pyrite from them. It also appeared that it made no difference whether the initial solutions were enriched in sulphuric acid and ferrous sulphate, or in acid potassium carbonate. The experiment was successful to the extent that it duplicated the results of nature by a method supposedly similar.

*From *California Journal of Technology*, November 1913; a detailed account of these experiments appeared in *Economic Geology*, August 1913.

ARRANGEMENT OF PLANT FOR MIXING CONVERTER SLAG AND FLUE-DUST.

fore altered, and its size increased. The gases from the converters were led through a large independent flue into a small subsidiary part of the dust-chamber at the base of the stack, and the finer material, as well as the dust, was extracted from the cupola charge and passed to the reverberatory furnace. A series of fresh experiments is about to be made to determine the efficiency of these conservative methods. But proof of their value is offered by the fact that the dust produced by the blast-furnaces has dropped from an average of 227 tons per day during the first half of 1912, when the reverberatory furnaces were not running, to an average of 116 tons per day since they started up.

Coarse Particles

The amount of coarse particles caught in the converter flue is two tons per day, but this is independent of the finer particles which settle in the brick-header at the base of the stack. That recovered in the flue itself is very high grade, analyzing as follows: An, 0.155 oz.; Ag, 15.4 oz.; Cu, 60.9%; SiO₂,

Handling Flue-Dust at the Copper Queen Smelter

By JAMES DOUGLAS

*Experiments made at the Copper Queen smelter during 1909-10 showed that by reducing the velocity of the gases in the dust-chamber and preventing eddies, a large amount of the dust loss could be avoided. The shape of the dust-chamber was there-

*Reply to discussion of paper, 'The Copper Queen Mines and Works,' presented before the Institution of Mining and Metallurgy.

MIXING DRUM FOR CONVERTER SLAG AND FLUE-DUST.

2.2% ; Fe, 8% ; S, 11.6 per cent:

A dust-chamber of 1200 sq. ft. cross-section and 132 ft. long was built, connected with the reverberatory furnaces, from the roof of which are hung some 30,000 wires. From this chamber, during a period of thirteen months, only nine tons of dust has been recovered. The dust in the chambers has not yet reached a point where the daily accumulation

LINERS FOR SLAG-DUST MACHINE.

can be regularly drawn off. Most of it, however, probably will always settle in the boilers and flues which are interposed between the furnaces and the dust-chamber. The dust-chamber connected with the McDougall roaster plant is 1370 sq. ft. cross-section. It is 144 ft. long, and has some 42,000 wires hanging from the roof. To date, the dust recovered is 6% of the charge roasted.

Frank Rutherford has furnished the drawings and following description of the converter slag and flue-dust sintering apparatus and methods at Douglas:

In June 1909 a cylinder 4 ft. in diameter and 9 ft. long, lined with firebrick, was set up in an inclined position so that the material made would discharge from the end. This machine soon demonstrated that a good product for blast-furnaces could be made by pouring molten converter slag and flue-dust together into one end of it, but that the crust or collars made were very difficult to remove. Naturally, the conditions suggested that instead of a cylinder a truncated cone would overcome all the difficulties and still give a good product. The working of the cone completely satisfied expectations as to dislodging the crust, and was a delightful surprise as to the tonnage it could handle. The conveyor, as shown in the drawing, was an essential part of the plan.

Operating Results

This machine ran for a number of months and proved conclusively the practicability of the process. The machine, working three shifts, easily handled all the converter slag made, and from 60 to 70 tons per day of flue-dust. The best and most even product was made when the dust used was from 18 to 20% of the converter slag by weight, and 25% was found to be the practical limit at which good coarse product could be made unmixed with flue-dust. The maximum day's product, 24 hours run, was 535 tons, with an average of 325 tons per working day over a period of five months, which included time taken for all minor repairs done while the shifts were on. The power was supplied by a 50-hp. motor through a train of gears and chain drive, and gave eight revolutions of the drum per minute. This speed might, with advantage, be somewhat reduced, and the method of drive be improved upon. Both of these changes would have been made had the experiments

been prolonged, but the reverberatory furnaces going into commission required all the flue-dust and brought the experiments to an end.

If the flue-dust contains much sulphur, the amount of sulphur dioxide gas liberated is very great, and provision for its removal must be made, and for collecting a small amount of fine dust. Trial runs made with matte instead of converter slag proved that, although the matte would take up much more flue-dust, the collars were much heavier than with the slag, and therefore harder to break. While working with converter slag and dust it was found that a small jet of water playing on the crust as it formed was sometimes quite a help, but with hot slag, free from white metal, the crust broke by its own weight, and therefore did not require the aid of a bar and hammer. Had the work been continued it would have been desirable to rebuild the machine, making it much heavier and increasing the diameter of the small end to about 6 ft. in order the better to dislodge the crust. Two of these cones have been installed in the new smelter of the Arizona Copper Co., Clifton, Arizona, primarily to mix fine silicious material with converter slag before going to the reverberatory furnaces, and thus obtain a better fluxing of this silicious material than could otherwise be obtained.

Mineral Production of Colorado

The following table has just been issued by the U. S. Geological Survey, and gives the value of the products for the past two years.

Mineral.	1911.	1912.
Clay products	\$ 1,606,709	\$ 1,437,394
Coal	14,747,764	16,345,336
Copper	1,003,061	1,172,705
Gems and precious stones	2,520	4,506
Gold	19,001,975	18,588,562
Lead	3,135,568	3,385,902
Lime	34,614	36,478
Manganiferous ore	109,340	12,646
Mineral waters	104,763	75,314

Sand and gravel	65,366	45,983
Silver	3,884,989	5,050,423
Stone	1,514,827	1,420,607
Tungsten ore	234,513	297,533
Zinc	5,392,625	9,123,374
Uranium and vanadium ores.....	302,000	*
Miscellaneous	1,153,678	970,975

Totals\$52,522,416 \$58,167,399

*Included in miscellaneous.

The value of the pig iron is not included, as the ores come from New Mexico and Wyoming.

Iowa increased its mineral production in 1912 by \$1,787,454 over the 1911 output of \$21,112,896, according to figures compiled by E. W. Parker, of the U. S. Geological Survey, in coöperation with the Iowa State Geological Survey. The value of the state's production of coal in 1912 was \$13,152,088, clay products \$4,522,326, portland cement \$2,790,396, an increase of 50%, and sand and gravel \$1,509,245.

Nearly 265,000 acres of land, previously withdrawn from entry in the United States, have been restored to the public domain recently.

Belgian Furnaces in Zinc Smelting

By GEORGE C. STONE

*It is frequently stated that there has been no change in the metallurgy of zinc since the first Belgian furnaces were built in the early part of the last century. It is true there have been no such spectacular and radical changes as were worked in the metallurgy of copper and iron by the introduction of converters; but, in the essentials, I believe the progress in zinc metallurgy has been as great as in that of the other common metals. The main reason that there have not been revolutionary changes is that the chemistry of zinc differs radically from that of the other metals and these differences control the type of apparatus that can be used. The differences are:

1. The temperature at which zinc is reduced by carbon is much above the volatilizing point of the metal and it is therefore always produced as a vapor.

2. To obtain a merchantable product the vapor must be condensed at a temperature well above the melting point of the metal. More than this, the temperature necessary to condense zinc depends on the concentration of its vapor and is lower the more dilute the vapor. When the mixture of zinc vapor and gases enters the condenser it is rich in zinc, and the condensation temperature must therefore be high in order to prevent sudden solidification and the production of blue powder. As the vapor leaves the condenser it is very dilute, and unless the condenser temperature is much lower there will be a loss of zinc. This means that the temperature of the condenser must be close to the boiling point of zinc (920°) nearest to the retort and very much lower at the opposite end.

3. The reaction by which most metals are obtained commercially is

With all the common metals but zinc, this reaction is only reversed when there is a considerable change in temperature or a very large increase in the concentration of CO_2 in the atmosphere. Neither of these is quite true of zinc. For any given temperature the equilibrium between CO_2 and the zinc vapor determines the amount of reaction. That is, the reduction of zinc proceeds until there is a certain ratio of CO_2 to zinc in the atmosphere and then stops. A decrease in the CO_2 causes the reaction to start again in the same direction, and an increase causes it to start in the opposite direction. The lower the temperature the less CO_2 it requires to reverse the reaction. In order to effect complete reduction this equilibrium must be continually destroyed by the presence of an excess of carbon, and the equation must be either

These three essential facts limit the possible apparatus for the production of zinc in several ways.

The reduction must take place in a closed chamber to prevent the loss of volatilized zinc. As the re-oxidation is proportional to the total CO_2 present, and not to its concentration, and as the difficulty of proper condensation increases very rapidly with dilution of the zinc vapor, the volume of gas going off with the zinc must be kept as small as possible. This means that the gases from the heating fuel must not come in contact with the charge, or, in other words, the heating must be external. As the mixture of ore and coal forming the charge is a poor conductor of heat, the size of the chamber containing it must be small in at least one direction or the heating will be too slow. The charge must, at all stages, contain a large excess of carbon to at once reduce all CO_2 formed. The condensers should be as close to the charge as possible and as small as will do the work in order to make it possible to maintain the proper heat gradient in them. The condensers must be kept within proper limits of temperature, diminishing toward the exit.

The first spelter furnaces built filled these conditions, and it is difficult to conceive of any other type that will do so.

Heat Consumption

It is commonly stated that the spelter furnace is very extravagant in heat. This I venture to question. Any furnace in which the issuing gases heat the incoming charge and thereby economize fuel is out of the question for reasons already given. It is therefore necessary to introduce cold charge in the furnace and heat it there. The heat used for this purpose is certainly not wasted. The heat escaping to the stack is not a large proportion of the total in a properly designed regenerative furnace supplied with gas of good quality, especially if waste-heat boilers are placed between the furnace and the stack. The main unavoidable loss of heat is by radiation. The end walls of the furnace are usually made very thick and the radiation from them is not great. The radiation from the roof is much greater, and is often excessive, as the roofs are usually thin. A great part of this loss can be prevented by covering the roof with a thick layer of porous material such as well burned boiler ashes. The main radiation is from the front of the furnace, and this is necessarily so, as the front must be made very thin in order to keep the retorts hot to the ends, otherwise there would be a considerable amount of unworked charge left in the front. But is this large radiation all loss? Considered only in relation to the heat required for reduction, yes; but considered in relation to the heat required for the entire operation, no. This heat is only sufficient, and not always sufficient, to keep the condensers up to the proper temperature, and it should therefore not be considered as lost, as heat from some other source would have to be supplied to the condensers if this were not available. This radiated heat regularly and automatically keeps

*Abstracted from a paper on 'Improvements in the Metallurgy of Zinc,' read before the New York Section of the American Institute of Mining Engineers.

the condensers at a suitably graded temperature, which would be difficult to do if they were heated in any other manner.

Forty or fifty years ago the typical Belgian furnace contained from fifty to ninety retorts of about 0.8 cu. ft. capacity each. At the present time the furnaces used in the natural-gas field contain from 500 to 700 retorts of about 1.4 ft. each, an increase in capacity of 1300%. Furnaces containing 1008 retorts are in operation, doing satisfactory work; this is an increase of about 2400% in size and capacity. The increase in capacity of the spelter furnaces is therefore about the same as that of the modern coke furnace making pig iron over the old charcoal furnace.

Increased Efficiency of Furnaces

Mere increase in size, however, does not amount to much unless accompanied by increased efficiency. In this respect the zinc furnaces show well. In the iron furnaces there has been no improvement in the proportion of metal recovered, the old furnaces having given almost theoretical results. With zinc the improvement has been very marked. In 1844, at the Vieille Montagne works, the recovery was about 62%, and even as late as 1880, 75% was considered good work. Today 87% is only fair and many works can show runs of long periods averaging 90% and over. The fuel consumption has been largely decreased, mainly by the adoption of regenerative gas-firing. A comparison of furnaces using the same kind of coal, shows that where the hand-fired furnaces 25 years ago required 2, 3½, and even 4 tons of coal per ton of ore, well equipped gas furnaces using the same coal and working the same class of ore now take only 1½ to 1¾ tons. Labor has also been largely reduced. The old Belgian furnaces required five days' labor per charge, two men working 24 hours continuously, and an extra helper on the day shift only. As these furnaces worked only about a ton of ore, they required five days' labor per ton. At present all 24-hour work is done away with, and not over 1½ days' labor is required per ton. In 1844 fifteen to twenty days was the usual life of a retort. Now good retorts made in hydraulic presses last from 30 to 40 days, and at that more are replaced because they are filled up than because they leak.

Regarding the future, I believe progress will continue to be made, but rather on the lines of improvement in the present processes than by the adoption of radically different ones. The present types of furnaces can be much improved. Fuel can be saved by better design and proportions of regenerators; better arrangement of the parts and decreasing radiation losses by more thorough lagging of the parts of the furnaces from which radiation is purely wasteful. A determination of the best size and shape of retort and condenser for different ores, and the choice of such as suit the particular ore to be worked instead of using one size and arrangement for all, will give improved results in recovery and output. A careful study and application of the principles on which ores should be mixed offers a wide field for improvement.

There have been a number of furnaces patented

for the production of zinc. Several of these are on the general lines of the present furnaces, and many of them show probabilities of being advantageous. Many others are shaft-furnaces, some heated by coal and some by electricity. Nearly all of these have the peculiarity of requiring the zinc vapor to go in one direction and the gases in another, which is obviously impossible of accomplishment. The coal-fired furnaces of this type have the additional disadvantage of producing a large volume of gas which would increase the amount of blue powder made and the difficulty of condensation. In the old days, metallurgy was purely empirical and progress was slow in all lines. Iron and steel were the first to be taken up by trained men, and the results they obtained were startling and revolutionary. Copper and lead followed next, with equally beneficial results. Zinc was about the last to employ trained metallurgists, but they have taken hold of it at last, and I have sufficient confidence in them to believe they will continue to improve on the good work they have already done.

Costs at the Oriental Consolidated Mines

According to the last annual report of this Company, reviewed in this journal of November 29, costs at the various mines and mills operated were as follows:

	Tons.	Cost per ton.
Mining:		
Tabowie	112,529	\$1.59
Taracol	93,558	1.91
Kuk San Dong North.....	12,757	1.00
Kuk San Dong South.....	13,774	0.81
Kuk San Dong Central.....	606	2.68
Kisen	6,986	1.02
Chintui	28,487	1.79
Charabowie	37,658	3.64
East Candlestick	6,463	4.88
Total and average	312,818	\$1.95
Ore transport:		
Taracol		\$0.02
Kuk San Dong		0.03
Chintui		0.03
Average per ton		\$0.01
Milling:		
Tabowie	112,529	\$0.44
Taracol	122,928	0.45
Kuk San Dong	34,123	0.64
Malbong	37,658	0.94
Candlestick	6,463	1.00
	313,701	\$0.54
Less receipts for milling tribute ore	883	0.75
Total and average.....	312,818	\$0.54
		Cost
	Tons	Per ton
Concentrate treatment:	treated.	treated.
Tabowie	12,863	\$3.48
Taracol	12,456	2.82

East Candlestick	6,463	1.19
Malbong (charges)	1,202	11.38
Total and average.....	36,952	\$2.91
General expenses averaged 40 cents per ton.		\$0.34

The Camanche Dredge, California

By C. G. LEESON

During February of this year the Oro Water, Light & Power Co. has started operating a dredge with 9-cu. ft. buckets at Wallace, Calaveras county, California, on lands adjacent to the Mokelumne river.

Details of Construction

The boat has a useful digging capacity of 40 ft. below water. The designers, who are also large dredge operators, call attention to the following important points. The hull is 45 ft. wide at the bottom, 115 ft. long, and 9 ft. deep, containing a total of 250,000 board feet of lumber. This was thoroughly dried and the hull treated with crude oil. The top spud strain is carried through four steel girders running above the screen and attached direct

bearing base. The main driving machinery has extra large shafts with four bearings on each intermediate and pulley shaft, and gears throughout the boat are steel with rim and spider integral. The main pulley shaft is divided in the middle and is connected by a large flange coupling, which also acts as a brake wheel for the main driving machinery. Flange couplings fitted in this way allow of adjustment of pinions for bearings on each side without offsetting keys. The main hopper, which receives the gravel from the buckets, is a large one and is lined with a cast steel hopper spout. The revolving screen is 6½ ft. diameter and 33 ft. long, and is made up of ¾ in. thick perforated, and liner plates made of 0.4% carbon steel. Screen tires are of exceptionally massive type with large bearing surface, many rivets, and with extension wings cast on for attaching longitudinal bars of screen. A screen thrust roller is carried at the top of the screen in an accessible position.

CAMANCHE DREDGE ON MOKELUMNE RIVER.

MAIN DRIVE SHAFT, BRAKE, AND GEAR.

to the main drive structural foundation, which is strongly anchored. Bow and stern gantry guys both anchor on the same foundation, thus counterbalancing gantry strains through the entire steel construction. The digging ladder is 83 ft. long, having a maximum depth of 8 ft., and being composed of two plate steel girders, cross bulkhead, and having a depressed carrying sniece on top. The bottom side of the ladder at the lower end is exceptionally well protected by heavy rider bars to keep the bucket line from abrading the under side of ladder. An effective lower tumbler rock guard is provided. The upper tumbler is the 'seat east on body type,' with a shaft 18 in. diameter, and heel plates 3 in. thick of manganese steel, supported by 3 in. of body metal underneath. These heel plates butt against a shoulder which effectually prevents shear on fastening bolts. Digging buckets are of the integral bottom and lip design, and weigh 1600 lb. each when machined. The lip weighs 420 lb., bucket pins are 5⅜ in. diameter, and the pitch is 327⁄8 in. Buckets are of 9-cu. ft. capacity, and the carrying angle is so designed as to minimize spill when the dredge is digging high. The ladder rollers are of manganese steel and are 16 in. diameter, and the bucket-line is designed to run 21 buckets per minute. All ladder hoist sheaves are 40 in. diameter, bronze bushed, and manganese steel castings, also the sheaves working on side lines, spud hoist lines, etc., are manganese steel castings. All bearings throughout the dredge rest upon a structural steel sub-base, and bearing cap bolts are capable of removal without disturbing

This roller is 24 in. diameter and is carried on a large long bearing. Gold-saving tables have a total area of 2000 sq. ft. on a single deck and are equipped with steel-lined Hungarian rifles. They are not covered by housing, but are enclosed by wire safety netting. The table area is supplied by two 10-in. Yuba Construction pumps, having a capacity of 2800 gal. per minute, each at 60 and 40-ft. heads, respectively.

Transformers on the dredge reduce electric current from 4400 to 440 volts. The main digging motor is 200 hp., and the motors total 465 horse-power. All electrical equipment is provided with automatic circuit-breakers, and oil switches, auto-starters, etc., are enclosed in steel air-tight boxes. Electric equipment is of General Electric Co.'s manufacture. The structural parts of the dredge were furnished by the Modern Steel Structural Co., of Waukesha, Wisconsin; and carbon and alloy castings were furnished by the Bucyrus Co., the Taylor, Wharton Iron & Steel Co., and the Edgar Allen American Manganese Steel Co., all parts thus furnished being made according to the specifications of the New York Machine Shop at Oroville. The total weight of machinery, including structural work, is 700,000 lb., and the boat cost \$160,000 in its completed condition.

Results of operation, in attacking an average gravel bank of 25 ft., show that the dredge is handling 75,000 cu. yd. more than estimated, the monthly total being 225,000 cu. yd., with an average running time of 20.5 hours per day. Gold recovery is 10c. per yard, and the boat is saving 50% more than prospecting indicated.

Portable Electric Mine Lamps

By H. H. CLARK

*Portable electric mine lamps are a comparatively new development in this country, although such lamps have been used in European mines for some time. For at least five years, and probably for a longer time, portable electric lamps have been used in the attempt to develop a satisfactory substitute for the safety lamp. There are a number of qualities that an electric lamp must have in order to make it acceptable for mine use. Chief among these is safety. The principal reason for the Bureau of Mines advocating the adoption of the electric lamp is that fire and explosion hazards will be thereby decreased. It is therefore manifest that the electric lamp itself must not be a source of danger. The Bureau proved by actual test that the glowing filaments of portable electric lamps are capable of igniting mine gas, but that sparks from portable electric lamp equipments of not more than six volts are not capable of igniting mine gas, unless the equipments are unusually large.

Permissible Lamps

Permissible portable electric lamps, according to the Mining Bureau, shall be so designed and constructed that under no circumstances can the bulb of a completely assembled lamp be broken while the lamp filament is glowing at a temperature sufficient to ignite explosive mixtures of mine gas and air.

The first requisite of an electric lamp is the production of light, and for mining service a lamp should burn steadily and with undimmed brilliancy for a certain number of hours of every day in the year. The next requisite is lightness, that is, a lamp should not weigh so much that it hampers a man's movements or becomes a burden to him. The cost of operation and maintenance should be consistent with the work done and the benefits received. It is also important that there is no leaking or spilling of electrolyte while the lamps are in use.

A true measure of the illuminating power of a portable electric lamp must consider not only the candlepower but also the angle over which the intensity is maintained. An intensity of light of one candlepower maintained all around a lamp results in twice as much light as if maintained only half way around the lamp. The term candlepower used without qualification is not only confusing, but really meaningless. If all sources of light distributed light equally in all directions, then a single measurement of their candlepower would suffice to compare them. Practically, however, sources of light differ a great deal in the way they distribute light, and this is especially true if reflectors are used. Therefore, if a lamp is stated to give two candlepower, the statement should also explain whether 'head on' candlepower is meant, or average candlepower over the stream of light, or average candlepower in a given plane—such as, for instance, the horizontal. A lamp that uses a reflector may have a 'head on' candlepower three to ten times the av-

erage candlepower over its entire stream of light. Generally it is best to state the average candlepower of a lamp instead of the candlepower at a single point or group of points. A statement of the candlepower of a lamp does not sufficiently define its light-giving capacity. A 100-cp. lamp is seemingly 33 times as desirable as a 3-cp. lamp, and yet a 100-cp. lamp shining through a hole $\frac{1}{2}$ inch in diameter gives less actual light and much less useful light than a 3-cp. lamp shining through a hole 3 inches in diameter. Therefore, in order properly to define the light-giving capacity of a lamp, a statement must be made regarding both the candlepower and the total flux of light produced by the lamp.

The Bureau suggests that lamps designed to be worn upon the cap should give the same intensity of light as that required for hand lamps, but that the minimum flux of light required from cap lamps should be not more than half the minimum demanded from hand lamps, because when a lamp is worn upon the head any light that is thrown to the rear is wasted. Twelve hours was selected by the Bureau as a reasonable time of burning. A lamp should be able to give the required light up to the time when the exhausted condition of the battery requires that the discharge be stopped in order not to impair the battery. Therefore, at least an hour of burning should be allowed over and above the usual requirements of the miner in order not to push the battery too hard in an emergency and to allow for possible incomplete charging. It is also not unreasonable to require 300 hours of actual service from each lamp bulb.

It is not necessary to suggest that anything should be well made if it is to be used underground. Under this head should be considered simplicity of design, strength of parts and fastenings, design of moving and removable parts, and the design and construction of electrical circuits and contacts.

Costs at the Oroya Black Range Mine

This gold mine is in Western Australia, and during the past fiscal year a total of 59,680 tons was mined and treated, at the following cost:

Ore extraction:	Per ton.
Breaking ore, including ore from development...	\$1.88
Filling stopes	0.05
Tramming and raising	1.14
Total	\$3.07
Ore treatment:	
Crushing	\$0.10
Milling	0.48
Treatment by vacuum-filter	1.14
Fine grinding sand	0.64
Cyaniding by percolation	0.62
Precipitation and melting	0.08
Disposal of residue	0.19
Total	\$3.25
Realization of bullion	0.10
Grand total	\$6.42

The Butters Salvador mine, in October, produced bullion worth \$49,000 from 3150 tons of ore, yielding a profit of \$20,000.

*Abstract from an address delivered on December 5, 1913, at Pittsburgh, before the Coal Mining Institute of America.

Dislodging Slime Cakes From Filter Media

Improvements in vacuum-filtration continue to be made by active workers in the field, and considerable litigation has been the result. United States patent No. 1,078,994 was granted on November 18, 1913, to Charles Butters for a 'Process of Dislodging Slime Cakes from Filter Media,' and the following notes are taken from the patent specifications.

In the treatment of slime, one of the most difficult and troublesome problems is to dislodge reliably and within an economical time, the slime cake from the surface of the filtering medium after the filtering process has been completed, without injuring the filtering surface of the leaf. It has been the practice heretofore to dislodge slime cakes by air-pressure from the interior of the leaves while suspended in the air, or this has been accomplished in some cases by water under pressure being passed through the filtering medium in a direction reverse

NEW BUTTERS FILTER LEAF.

to that of the filtrate. It has been supposed that, to remove the cake reliably, pressure was necessary, whether air, water, or other fluid was used in the process, whether used interiorly or exteriorly. When used interiorly, special precaution has sometimes been taken to get a uniformly thick, cohesive, and resistant cake, such that the fluid under pressure might dislodge it as an entirety, and make it unnecessary to use additional means to dislodge the cake completely. By the new process such uniformity of the cake is of no importance at all to the cake dislodgment, and consequently the filtering operation may be more economical.

In practice, it is found that slime cakes have great adhesion and cohesion, and that when a cake is formed on each side of a filter-leaf they are not easily dislodged. This adhesion depends on the percentage of water in the slime, and partly on the character of the filtering surface. Mr. Butters has found that from a comparatively smooth filter surface the cake can be removed if it is first partly dried and then copiously flooded externally. A cake at the end of the filtering process, before special drying, contains about 30% moisture. By the drying step, the highest vacuum being maintained on the cake for 5 to 10 minutes while it is suspended in air, the moisture is reduced to about 20%, and may be more

or less concentrated toward the inner parts of the cake. The drying also tends to crack the cake at the top, and initiate there a separation of the cake from the filter. Then the vacuum is shut off, and water applied at this point, immediately dislodging the cake.

The Filter Leaf

Referring to the numbers in the accompanying illustration, the filter leaf is described as follows: The leaf consists of headers 12, which support it on shoulders 31, of the vats; a fibrous filler 13, preferably of cocoa mat; and a filtering medium 14, such as canvas, mounted on each side of a frame and the cocoa mat. The medium may be composed of two pieces sewed along the sides and clamped at the top between the headers 12, or it may be a single piece sewed on the sides, clamped at the top between the headers and open across the bottom. The open portions extend 6 to 8 in. below the frame member 15. The extended open portion of the medium 14 may be stitched every 9 or 10 in. as shown. This type of leaf is preferred, although others may be used. Connections 4 communicate with the interior of the leaves through the frame members 8, 9, and 11. The lower frame member 9 is perforated or slotted along its upper side, and the upper one along its lower side in the well known manner. A vacuum pump 3 is connected with the interior of the leaves through the pipe 7, valves 6, sight glasses 5, connections 4, and members 8, and perforated members 9 and 11. The members 8, 9, 10, and 11 are connected so as to form a rigid frame structure, and are all in open communication with one another. No. 10 extends upward through headers 12 to a T joint 16. In this extension is a plug 19 to seal the vacuum there and prevent the entrance of water from the pipe 26 to the leaf. In order to place the leaves easily in the vats, spacers 27 are put on the sides and are held in place by bolts 28 through them. A pipe 17, perforated along its lower side with, say, 1/4-in. holes 3 in. apart, is supported above the headers 12 of each leaf, and above the top of the slime pulp in the vat, and so above the top of the cake on the filter leaf by means of straps 17. They may be bolted through the headers by bolts 18, and may bend around the pipe and have a bolt 21 passing through the straps below the pipe. To remove the leaves at any time, holes 20 are provided in the headers 12 for the insertion of hooks. Connected with pipe 15 is a pressure pump 22, through valve 23, pipe 24, valves 25, and connections 26. By this means water at any desired pressure comes from the pipe 15 on top of the headers 12. The header will take the pressure of water rather than the cake, and the water will merely run down over the leaf and its attached cake without any great pressure.

Indiana in 1912 produced minerals to the value of \$42,239,193, an increase of nearly \$5,000,000 compared with \$37,439,187, the production of 1911. The 1912 figures, however, do not include the value of the pig iron produced in the state, which was more than \$17,000,000. The principal products of the state are coal, clay, cement, and stone, these having a value of 90% of the total output.

Mining Conditions in Western Chihuahua

From a recent report to the shareholders of the Rio Plata Mining Co., by Henry W. Miller, president of that Company, the following relative to the conditions under which mining is being conducted in some parts of Mexico is abstracted. The property of the Company is situated in the Sierra Madre mountains near the western boundary of the state of Chihuahua at a distance of about 250 miles southwest from the city of Chihuahua.

The Mexican revolution, which has now been going on for about three years, has increased greatly in violence during the past year, and has caused more serious interruptions to business than in previous years. Many properties of mining and commercial companies have been damaged; a great many companies have been forced to stop business; both life and property have been placed in peril. We have been able so far to keep possession of our property and obtain a limited number of workmen with whom the development at the mine has been continuously carried on. Thus the safeguarding of the works and improvements had been successfully accomplished to the date of the last advices from the mine, October 8. These unsettled conditions compelled curtailment of mining and milling during all these years. Labor, always scarce, has been made more so by the incessant drafting of the able bodied men into the armies. Procurement and transportation of food and operating supplies heretofore has been difficult, but this year it has been almost impossible. The ore mined a year ago and treated in the Company's mill in the last quarter of the fiscal year 1912, is the last that has been treated. Operation of the reduction works, during the present year, would have been impossible for the want of supplies and men, even if millable ores in sufficient quantities had been ready for treatment, and the further shipping of the product in safety would have been entirely out of the question.

During the current year, railroad transportation and trail freight routes used heretofore by the Company have been out of commission or abandoned; mails have been slow, irregular, unreliable; no telegraphic connection with the mine or with any place near it, and runners sent from the mine, and to the mine from the city of Chihuahua and elsewhere, with messages, letters, reports, orders, etc., have been stopped or detained by the different revolutionary factions—papers greatly delayed, some of them lost or destroyed. To illustrate: A transfer of \$5000 bank credit from Chihuahua to Alamos arrived, but the acknowledgment was not received by the Chihuahua bank until September, and notice from the Alamos bank to the mine superintendent was never received. From general information during August it was learned that the Alamos bank had been forced to stop business some time in May.

Shipments of dynamite and powder are prohibited. Revolutionists have been almost constantly active and troublesome in different parts of the country districts between the mine and the city of Chihuahua. Supplies could not be safely transported from Chi-

huahua at any time after December of last year. Goods, supplies, and money could not be sent out over the trail in the usual way. These the superintendent procured by various means for a time from Alamos and later from other quarters. At times and especially in recent months he obtained powder and other supplies from different mining companies in nearby districts which had been forced to stop operations.

The Company's correspondence since last May has been sent from El Paso, Texas, to Chihuahua by private conveyance and by special runners from Chihuahua to the mine, a total distance of five hundred miles across a rough country in all parts of which either federal or revolutionary troops and bandits have been and are carrying on warlike operations. Reports from the mine have been sent out in the same manner.

Counterbalancing Hoists

A new system of counterbalancing hoists, for which patent is being applied by Letson Balliet, manager for the Buckeye-Belmont mines at Tonopah, who supplies the following account.

When skips or cages used in hoisting are run upon double-drum hoists the process is called 'hoisting in balance' which technically is not the case, for when the empty skip, cage, or bucket is to be returned to the bottom of the shaft it is lightest when leaving the top, and often is lighter than the weight of the cable that is extended down the shaft to the other cage or skip. The loaded skip or cage with the cable on leaving the bottom is the heaviest, or at its heaviest, when the empty skip is giving it the least aid. Furthermore, the total friction loss averages from 30 to 40% of the power used in hoisting, as can easily be verified by computing the work done, in foot-pounds, when hoisting a known weight or load, and subtracting it from the meter reading for the trip, or indicator card of the power actually used. It is evident that the double-drum balancing system helps a little, but it is far from being efficient. Moreover, the weights are frequently 'out of balance' with the cages at different levels.

Another form of balance is a transverse balance, where a weight suspended in a pipe, wooden flume, or on a guide, is directly connected with the cage or skip, by a cable that is passed over a sheave, like the old fashioned well buckets, where two buckets are handled on one rope, over a pulley suspended above. This form of 'direct balancing' has a greater efficiency than the double-drum hoist, because it eliminates the gears and mechanical friction of one side of the hoist, and the cable wind upon the drum. It is limited to shallow mines, for manifestly there will come a time when the weight of the cable on the counterweight, plus the weight of the skip or cage, would outweigh the counterweight and pull it into the sheave. Conversely, the counterweight, plus the weight of the cable when the counterweight is down would weigh so much that the empty skip, or cage, would not descend. Like the double-drum hoisting, the counter-

weight is lightest when the loaded skip or cage is to be lifted from the bottom, at which time the counterweight rope is extended down the shaft and attached to the load. In some shallow mines, a tailrope system has been installed where a sheave at the bottom allows a cable to run from the counterweight to the skip or cage. This compensates the weight of the cable nicely, but it has some disadvantages and limitations. It must be kept tight or the lower rope gets out of the sheave, lubrication is difficult, and the extra rope is always hanging in the shaft. If in water or a 'wet-shaft,' troubles may multiply, and a dropping rock or a falling car, cage, or skip, makes a worse condition than ever, with a broken sheave and tangled rope to remove. The Balliet system of counterweighting consists of a superimposed sheave-wheel in the head-frame, with an extra cable running from the skip or cage over the upper sheave and down to the counterweight. The mathematics of the system is that of two variables, wherein the skip or cage and its rope is changing weight at all points, which must be counterbalanced in the other shaft by a gain of weight at all points. Thus when the empty skip is at the top and counterweight resting upon the bottom, the weight of the rope only prevents the skip from starting down. At the instant it starts from its topmost point it takes up, without jolt or jar, a weight which still leaves the empty skip or cage about 350 to 400 lb. heavier than the weight and its rope. This allows the skip to get a good start and causes it to gain weight as the rope gets longer on the skip side, and shorter on the counterweight side. As the weight rises, it follows a guide and takes up additional weight at all points, increasing in weight faster than the skip does, until it becomes in exact balance at the bottom, or at any point where it is desired to set the balancing system.

Advantages of the System

One advantage of this system is that the skips or cages do not accelerate, but maintain practically a uniform speed in descending until near the bottom, where they begin to go slower. Another advantage is that a skip operating in a shaft with any number of levels can be set in a few seconds time to stop or come to balance at any level desired, and it cannot descend to lower levels till the balance is adjusted for the purpose. A shaft a few feet deeper than the lowest level, can have the weight so adjusted that if the counterweight alone is holding the skip or cage, when the hoisting rope breaks or a runaway drum accident happens, the skip will come to rest at a balance suspended above the bottom, without jar, damage, or injury, even if the dogs and the cut-off latch fail to hold. The weights can be increased instantly, but are picked up gradually without jar by the engineer giving a pull at a lever. It also automatically increases if the engineer overwinds. It cannot be ignored by the engineer in overspeeding, nor can it be put out of balance, but will always run as it is set. It can be applied to either single or double-drum hoists and to passenger elevators. It is 'fool proof' in that a skip or cage loaded with men can be cut loose at the top and its descent will be only at the speed it is set to travel,

until the ever increasing counterweights overbalance the load and bring it to rest suspended in the shaft. It can be installed in any vertical or near-vertical shaft. It removes the peakloads to considerable extent, because the greatest weight of the counterbalance is when it is up and the loaded cage is ready to be lifted. It reduces the power costs by the amount required to handle the dead weight unbalanced. In the case of double-drum hoists each cage is balanced independently of the other, exactly as if they were two single-drum hoists.

No power is required for the descent of the skip or cage, as the latent energy exerted by the skip or cage descending by gravity picks up just as much load as it can carry until it picks up enough to bring the skip or cage to rest at any point desired. The latent power, having been transferred from the skip to the weight, is then ready to aid in raising the skip when it is loaded. When the hoist is started it has to overcome the net load placed on the skip, while the counterweight handles the dead weight of the skip and cable.

Hoisting at the Buckeye-Belmont

In the Buckeye-Belmont No. 1 shaft the skip weighs 1600 lb., 1200 ft. of cable weighs 744 lb. (the cable required to run from the collar up over the sheave and back to the collar is balanced and need not be considered), the counterweight itself weighs 500 lb., while the variable weight adds 1768 lb. It will be seen that when the skip is dropping back out of the tippie, much of its weight is over the bin and not in the guides—at this point the 500-lb. weight rests on the bottom and the skip needs balance only 744 lb. of counterweight cable. At the instant that the skip rights itself and its whole weight is in the guides, the engineer lowers it out of the tippie with the brake, and the cable tightens on the 500-lb. weight. At this instant the 1600-lb. skip is offset by 500 lb. plus 744 lb. of cable, or 1244 lb. total.

It will be seen that the empty skip overbalances the counterweight and its rope by 356 lb., which allows it to be returned promptly, and it starts immediately. The counterweight comes up, following a guide in the manway or other compartment, picking up weight at all points as the empty skip descends in the working shaft. It is evident that when the skip reaches the bottom it will have 1600 lb. weight plus the 744 lb. of counterweight cable which has been pulled into the working shaft by the descent, and meanwhile the counterweight has ascended to the top of the shaft and has picked up 1768 lb. of weight in addition to its original 500 lb., which gives 2268 lb. total counterbalance weight, to lift the 2344 lb. of deadweight upon the hoisting side. This 76 lb. difference was necessary in this case, to allow the skip to sink into the sump a distance of one inch over the bailing valve in the side of the skip.

Taking 4c. per kilowatt as a basis of power-cost, the same skip unbalanced hoisted 1500 lb. at a cost of 14c. per trip for power, two trips 28c.; with the balance the skip is filled with 3000 lb. of ore or rock, and costs 10c. per trip. It is easier upon the motors, machinery, and head-frame, as every jar and vibration is removed. The entire cost of this installation was about \$850.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Publication of any contribution is determined by its probable interest to the readers of this journal.

Water in Veins

The Editor:

Sir—T. A. Rickard's invitation, on pages 693 and 694 of the issue for November 1, with its R. S. V. P. demands, according to the usages of polite society, an acknowledgment without delay. All his friends concerned in the invitation would do so promptly and frankly under any circumstances, but most of all when it is evident that one for whom and for whose writings all entertain a particularly high regard, feels himself to be suffering from a failure on their part to properly recognize and cite his published work. It may be stated very positively at the outset that no one would fail to do so for the reasons mentioned in his letter, since his contributions to mining geology are everywhere recognized to be the results of world-wide and accurate observation, and to be illustrated with an extremely faithful pencil. In the present instance, the nature of the early records in Mr. Rickard's papers themselves seem to the writer to furnish a sufficient defense for not citing them as having priority in the question of the shallow zone of the ground-waters. As to the lack of ground-waters in the depths of at least one unusually deep mine, there is a record of almost identical purport with Mr. Rickard's, and about six years earlier.

The paper on 'The Cripple Creek Volcano' was read at the Washington meeting of the American Institute of Mining Engineers, February 1900, and was published in Vol. XXX of the *Transactions*, pp. 367-403. In the portion of the paper from which Mr. Rickard quotes in his letter, he is discussing the agency of water in causing explosive volcanic out-breaks. In his view, the water is derived from the surface, by downward movement; that is, in our modern phrase, it is meteoric in nature and not magmatic. The full paragraph, pp. 376-377, reads as follows:

"There is therefore ample evidence that water does penetrate into the conduit of the volcano, and that it is originally derived from the surface. As against the contrary belief, namely, that the water vapor accompanying eruptions is an essential constituent of the lava, and therefore shares with it a deep-seated origin, there is the following evidence. It has been found, as the result of a large number of accurate observations in wells, shafts, and bore-holes that the temperature underground increases 1°F. for every 48 ft. of descent. At 7776 ft., the boiling point, and at 34,700 ft. the critical point, 773°F., of water would be reached. The exhaustive force of steam increases rapidly with the temperature, so that at 773°F. it would be equal to the pressure of 350 atmospheres. This is termed the 'critical point,' because, at this temperature, water, however great

the pressure to which it is subjected, can no longer exist as a liquid, but becomes dissociated into its constituent gases. Although the exact conditions which obtain at these great depths cannot be known with certainty, nevertheless all the evidence goes to show that there is a limit set to the descent of surface water by the rapid increase in the expansive force of its vapor, due to the rising temperature. Prestwich put the maximum limit at 6 to 7 miles, and Delesse estimated it at 60,000 ft., or about 11 miles. Moreover, experience goes to show that the water encountered in mines is the drainage from the surface. Deep mines are usually dry ones. I may instance the deepest metal mines, the Calumet & Hecla and Tamarack, in the Lake Superior region, and the '180,' 'New Chum-Victoria,' and neighboring shafts, at Bendigo, in Australia."

We can only infer from this passage that Mr. Rickard was arguing for the deep descent of the surface waters and adduces in proof the obvious experience that the water encountered in mines comes from the surface. All the context goes to show that the dryness of deep mines never suggested itself as an argument for shallow ground-waters. Additional corroboration will be found on pp. 219-220 of Vol. XXXI, 1901, of the *Transactions*, in Mr. Rickard's paper on 'The Formation of Bonanzas in Gold Veins,' in which, a year after the paper on the Cripple Creek volcano, he writes as follows:

"It does not appear to me that Professor Van Hise has erred by exaggerating any particular view of the subject. His elucidation of the water circulation as a complete system is based on a broad conception of the whole matter," etc. The reference to Van Hise means his views as expressed in the paper entitled 'Some Principles Controlling the Deposition of Ores,' which was read at the Washington meeting of the Institute, February 1900, and published on pp. 27-177 of Vol. XXX of the *Transactions*. Whatever views are expressed in this paper, the shallowness of the zone of meteoric waters is not among them, since the paper is a strong argument for exactly the reverse. Its great feature is the descent of the meteoric waters possibly even to the limit of cavities, their migrations through the rocks and return by trunk channels to the surface.

It does seem strange as we look back upon the animated and interesting discussions of this period, that participants generally were not moved to check up their conclusions by the actual experience of the miner and the driller. Instead, however, of basing reasoning about deep-seated waters primarily on facts of observation, almost everyone was so deeply under the influence of the time-honored views inherited from Delesse, Prestwich, and other early writers, and from the experience in the shallow mines of preceding generations, that this new evidence was either overlooked or twisted into a support for the old-time conceptions. While I would not wish to exaggerate its significance, I do not think that its force is generally appreciated today. Could we have attacked the problem of the deep veins and orebodies primarily with these facts in mind, we might well have felt forced to look around for some other kind of water. So far as I know the first con-

tribution in which this attitude is taken, is the one in Vol. XXXI, pp. 169-197, 1901, of the *Transactions*, where on pp. 184-195 the subject is set forth with some fullness. The question of priority interests the author of this paper but little, but the importance of securing for these matters a proper place in the discussions is great. I can say for him, now, that he regrets at the time he did not know of Mr. Rickard's mention of the Keweenaw Point and Bendigo Deep mines the year before so that the latter could have been cited and acknowledgments made. Keweenaw Point, however, was no new thing and had been well known to him from personal visits for nearly twenty years. The omission of Mr. Rickard's remark was quite unintentional.

Nevertheless in the contribution on 'Water in Veins—A Theory' in *The Engineering and Mining Journal* for March 14, 1903, two years later, Mr. Rickard makes no mention of this earlier contribution, although he traverses almost the same ground. The next year, 1904, in the *Proceedings of the Colorado Scientific Society*, J. W. Finch brought out his interesting discussion entitled, 'The Circulation of Underground Aqueous Solutions and the Deposition of Lode-ores.' (Vol. VII, pp. 193-252) Mr. Finch takes a decided stand for a zone of meteoric ground-water even shallower than had been believed by the earlier writers. Perhaps these citations will correctly set forth the matters of priority, except so far as the point of decrease and final absence of the application of these facts to its distribution.

Posepny certainly knew that the surface waters decreased and finally failed at Przibram, since he writes as follows in Vol. XXIV of the *Transactions of the American Institute of Mining Engineers*, p. 971, 1894:

"The Przibram district lies in round numbers, about 500 metres above sea-level, and the mine-workings extend as is well known to more than that distance below sea-level. The ground-water level is but a few metres under the surface. The deepest adit drains the mines to about 100 metres; and everything below that level is strictly deep workings, from which the water is lifted to the adit-horizon. A comparison of the water raised from different levels shows that the largest quantities come from the upper ones, and that the amounts diminished with increasing depth, so that at about 300 metres below sea-level no water remains to be raised, the ruling rock and air temperature of about 23°C. (74°F.) at that depth sufficing to evaporate the small existing quantity of water. This is certainly a striking proof that the water encountered in mining is of atmospheric origin." The mines were developed to about 1100 metres from the surface, leaving some 300 metres at the bottom practically free from water. What efforts, if any, were made to impound the waters immediately below the 100 metre adit, Posepny does not state.

In preparing the paper on the 'Rôle of the Igneous Rocks in the Formation of Veins' for the meeting of the Institute of February 1901, I consulted with my colleague, H. S. Munroe, of the department of mining, and received confirmation of my own impressions that the general experience in deep mines was that, with the impounding of the waters in the

upper levels, pumping became unnecessary at greater depths. The deep dry well at Wheeling, West Virginia, had been a matter of record for ten years, and the deeper one at Pittsburgh for four years. The application of all these and others as an argument for a shallow zone for the ground-waters was with some justice considered new.

In closing, I can only express the wish to have treated this uncomfortable subject in a proper manner and one calculated to bring out the truth and to give no offence. No one could wish more than I, to see Mr. Rickard get all due credit and recognition for his contributions on the ground-waters and all other subjects; and likewise that justifiable claims to priority should also be no less recognized.

J. F. KEMP.

New York, November 17.

The accumulation of helium in the rocks and the radium, uranium, and lead ratios probably serve as the best recorders of time that geologists possess. The work of Strutt and others in determining these ratios indicate that the earth is really an old world after all. The ages of the various rocks on this basis are about as follows:

Class of rock.	Years.
Carboniferous	340,000,000
Devonian	370,000,000
Ordovician	430,000,000
Algonkian	1,000,000,000
Archean	1,300,000,000 to 1,600,000,000

Continued work of this kind will perhaps serve as a very important aid in really making geology a chronological science and giving dates to geological history.

The principal mineral product of Kentucky is coal, which in value constitutes about three-fourths of the state's total mineral output. In 1912 the value of Kentucky's mineral production was \$22,452,984, of which the coal output made up \$16,854,207, according to figures compiled by E. W. Parker, of the U. S. Geological Survey, in coöperation with the Kentucky State Geological Survey. The increase in the total mineral production over 1911 is \$3,156,370. The clay-working industry is second in importance in the state, with manufactured products in 1912 valued at \$2,413,740, against \$2,368,094 in 1911. The principal clay products are firebrick and other forms of refractory material made from fire-clay and common brick.

The work of the United States Geological Survey is reflected chiefly in the publication and distribution of its printed reports and maps. According to the annual report of the Director, recently made to the Secretary of the Interior, during the fiscal year ended June 30, 1913, the number of reports printed was 253,850 copies, and the number distributed of these reports and reports previously printed was 375,213 copies. The reports are sent out only on application.

The ore minerals at the Mount Lyell mine, Tasmania, in the order of their observed prominence, are pyrite, chalcopyrite, enargite, tetrahedrite, sphalerite, galena, hornite, and chalcocite.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Operating costs at the North Broken Hill mine are: mining, \$3.04; development, \$0.60; and milling, \$0.84 per ton.

Franckeite is a sulphide of tin, composed of $Pb_5Sn_2Sb_2S_8$, or $2PbSn_2Pb_3Sb_2S_8$, found in the province of Oruro, Bolivia.

After 30 years, land in the Joplin district, Missouri, on which the regular taxes have not been paid, reverts to the state, and is sold for delinquent taxes.

Shovelers at Joplin, Missouri, average 19.7 tons per man per shift. They are usually paid by the tub, 4 to 8 cents each, these being 28 by 30, 30 by 30, and 30 by 32 inches in size, holding from 850 to 1100 pounds.

Javanese coolies working at the Ketahoen mine, Sumatra, are paid from 16 to 24 cents per day, depending on length of service, not ability. A white miner gets from \$100 to \$130 per month, his work consisting mainly of supervising natives.

Costs of milling at the Nevada Wonder mine were as follows during the past year, in the treatment of 39,118 tons: direct, \$3.092; indirect, \$0.157; making a total of \$3.249 per ton. The recovery was 93.1% of the metal contents, the ore containing approximately 70 of silver to 1 of gold.

Spares used in the Oriental Consolidated company's five mills, containing 240 stamps, which crushed a total of 313,701 tons of ore during the past year, were as follows: 658 shoes, 454 dies, 14 heads, 10 tappets, 23 cams, 7 cam shafts, 8 stems, and 3 pulley flanges. The consumption of quicksilver was 21,500 ounces.

In making geologic notes underground, a simple color scheme has been adopted at the Anaconda Copper Mining Co.'s mines. Red pencils are used to indicate vein filling, which may be ore, barren pyrite, in fact any metallic mineral or quartz, and the record of the minerals present is found in the written notes. Blue coloring indicates evidence of faulting, either as the definite planes of movement or the crushed granite resulting from such movements.

Consumption of chemicals at the four cyanide plants of the Oriental Consolidated company, during the last fiscal year, was as follows:

Chemical.	Quantity, pounds.	Cost per ton treated.
Cyanide	167,330	\$0.56
Zinc and zinc dust	50,200	0.07
Borax	10,640	0.04
Lime	818,385	0.11
Soda	4,256	0.005
Litharge	1,456	

A total of 53,923 tons of products was treated.

Cobalt has been often tried as a steel alloy without making a notable improvement in the resulting steel. There has recently come on the market a German product known as 'iridium steel.' It contains cobalt, but no iridium, and its price is prohibitive. Its analysis shows: cobalt, 4.25%; tungsten, 16%; chromium, 3.55%; vanadium, 0.67%; molybdenum, 0.80%; carbon, 0.60%; a low percentage of manganese, silicon, sulphur, and phosphorus; and 74% of iron.

Comparing the Waihi deposits described in the 'Geology of the Waihi-Tairua Subdivision, Hauraki, Auckland,' by J. M. Bell and Colin Fraser, with the Tonopah deposits described by J. E. Spurr, one is impressed with the many similar features of the two regions, according to W. H. Emmons in *Economic Geology*. Both groups of deposits are in igneous rocks of comparatively late age, nearly related in composition; both are capped in places by later barren rocks. The ores of both carry carbonates and adularia, and the proportion of sulphides to gangue minerals is low in the ore of both districts. Tellurides and selenides are present in both, and the lists of ore minerals are closely similar, although the proportions of the minerals present show considerable variation. Hydrothermal alteration, as already pointed out by Finlayson, is closely similar—silicification, sericitization, and development of adularia and carbonates being the dominant hydrothermal processes in both regions.

Recovering gold from gravel dug by dredges is simple. After leaving the buckets, the gravel passes either through a revolving or over a shaking screen, this eliminating all material over about half-inch size, while the finer sand and gravel passes through the screen to the bottom of a hopper. During its passage through the screen, water is added copiously to the gravel to disintegrate it, also at the bottom of the hopper below the screen, from which the pulp flows over a series of riffles. These usually cover a large area on the boats, and consist of either strips of beveled pine shod with $\frac{1}{8}$ by $1\frac{1}{4}$ -in. iron, or of 1 by 1 by $\frac{3}{16}$ -in. angle-iron riveted together. Quicksilver is added to the riffles and the gold caught as the pulp flows across them, and two or three times per month all the fine gravel and sand and amalgam is collected and washed. The accompanying half-

PART OF GOLD-SAVING TABLES ON CAMANCHE DREDGE.

tone shows part of the revolving screen, hopper, water pipes, and riffles on the Camanche dredge described on another page of this issue.

LITIGATION BETWEEN ELMORES AND THE MINERALS SEPARATION.—THE MESSINA COPPER MINE AND ITS DEVELOPMENT.

An unusual event has happened in connection with the hearing of the appeal of the Elmores, before the Judicial Committee of the Privy Council, against the judgment of the New South Wales court in connection with their suit for infringement of patents on the part of the Sulphide Corporation which uses the Minerals Separation process. The appeal was heard early in November and judgment was reserved. Now comes the news that the case is to be re-argued in January next. A vast amount of speculation has been rife as to the meaning of this hitch, and at the time of writing I have not heard that the Lord Chancellor has divulged the reason why the views of the judges have not been given or accepted. It is assumed, however, that the three judges were not unanimous and that a majority judgment in so small a court would not be acceptable in Australia. The constitution of the court was a strange one, for two of the judges had already passed opinions in connection with the English litigation, one on each side. Lord Moulton, who had been in favor of the Elmores in the Court of Appeal, did not hesitate to express his opinion forcibly at the recent hearing, thereby disconcerting his brother judges and the counsel engaged. Lord Moulton ought never to have been on the bench in connection with these patents, for before his elevation he had given an opinion as to the validity of the first Elmore patent. In an American court this fact would be sufficient to disqualify him from sitting on the case. I am not aware that Minerals Separation raised the point, or whether it would have done any good if it had been done, but the Company would surely have been fully justified in objecting to his association with the case. In the course of a week or two I shall have further news to send.

After many years of struggle the Messina copper mine, in the north of the Transvaal, has arrived at the profitable stage. It is a round dozen of years since A. M. and J. P. Grenfell had their attention drawn to the old workings just south of the Rhodesian border. They visited the property, and after due inspection decided to make the financial plunge. These two gentlemen are well known in the United States, Canada, and Mexico in connection with their multifarious land and mining interests, and Camp Bird and Santa Gertrudis may be mentioned in particular. More recently the name of Grenfell has become associated with the General Petroleum of California. The Messina mine contains a rich ore deposit, but, owing to absence of railway communication, the cost of development and of realization on the ore won was abnormally high, and for years the sale of ore in Swansea, Wales, was only sufficient to pay for development. The method of handling the property has proved satisfactory, however, for the Company has not been overburdened with capital. At the present moment the profit in sight is over five times the nominal capital. Naturally the shares stand at a big premium, but not too much so, considering the excellent prospects at the mine and the other copper deposits at present undeveloped, not to mention the coal mine owned by the Company. The great event of the day is the completion of the railway connecting the mine with Pretoria and Cape Town. Another railway is in hand to connect with the Selati railway which runs from Leydsdorp to Delagoa bay on the east coast of Africa. Two reverberatory furnaces have just been put into commission under the metallurgical management of T. D. Nicholls, who was for many years with the Cape Copper Co., and is known among copper people as the co-inventor with the late Christopher James of the 'direct' method. During the past 12 months, 3462 tons of picked ore and jig concentrate was shipped to Swansea, averaging 45 to 50% copper, and a profit was made of £29,734. An account of the ore deposit will be

of interest to readers. The ancient workings are all open-cuts, and some are as deep as 80 feet. Most of them have been filled with debris, presumably by the old miners as the faces advanced. The workings approximately follow three lines, which have since been identified with definite lodes, and named the North, Middle, and South lodes. Their general trend is northeast to southwest, and they approach each other toward the west. The country for a mile round the mine is granite, with hornblende-gabbro dikes penetrating it in various directions. On the line of lodes many other rocks are found, principally decomposed or altered granites. Both red and gray granites, frequently of a gneissic structure, are exposed in the cross-cuts between the lodes. Soft decomposed felsites, in substance like china-clay, and colored yellow, red, or green, are associated with the lodes in some places. Elsewhere white quartz is the gangue of the lodes. The copper minerals are chalcocite, bornite, and chalcophyrite, and they are found occasionally in large irregular blocks, at other places cemented in the cracks of the quartz or disse-

SECTION ACROSS THREE LODES IN MESSINA MINE.

minated through its mass. When prospecting was started, seven shafts were sunk, three on the line of the North, three on the South, and one on the Middle lode. At first the results were disappointing. It was not until cross-cuts were driven on the No. 1 and 2 levels from the shaft on the Middle lode to the North lode that a large body of ore was found in the latter. This was called the Bonanza. It forms part of the North lode, and on the upper levels was about 100 ft. long and from 25 to 40 ft. thick, consisting of chalcophyrite and bornite mixed with felsite. The North lode has been exposed for 1500 ft. along the strike on the second level, and has been proved to a depth of 900 ft. The ore-shoots consist of a series of lenticular masses having no observable connection between each other. The lode is generally 3 to 4 ft. wide, with granite walls. At places it widens to 10 or 20 ft. where it includes granite 'horses.' In the Bonanza stope the copper minerals are disseminated in irregular blocks throughout the mass, and the gangue and wall rock are much decomposed. In depth the proportion of chalcophyrite decreases. Below No. 3 level the Bonanza stope splits into two parts. The Middle lode is more erratic than the North lode and is about 2 ft. wide, consisting of bornite and chalcophyrite, widening occasionally to 20 ft. with 'horses' of granite interposed. The South lode has been worked to No. 4 level and consists of chalcocite and quartz within hard granite walls. Occasionally it splits into two parts, each about 3 ft. thick, separated by 3 to 6-ft. granite through which stringers of ore penetrate from one side to the other. An excellent account of the mine was recently given by the manager, J. A. Woodburn, to the South African Society.

WASHINGTON, D. C.

BUREAU OF MINES ESTIMATES.—PROPOSED PETROLEUM INVESTIGATIONS.—ALASKAN RAILWAYS.—LAND LAW REVISION.

Estimates for appropriations for the United States Bureau of Mines, approved by the Secretary and submitted to Congress, call for \$752,000, an increase of \$90,000 over the current appropriation. The principal new items are \$30,000 for equipment of mine-rescue stations and cars, and \$30,000 for petroleum investigations. The first is made necessary by the fact that the old cars, originally the gift of the Pullman company, are about worn out. This is not surprising, since, when they were planned, such work was entirely new and experimental. The Pullman company generously gave to the Bureau a number of old sleeping cars which were converted to their new use. Since then steel cars and steel-frame cars have come to be the standard equipment for first-class trains. As a result, a number of these older cars can not be hauled upon the fastest trains, a fact that may at any time prove of first importance. To reconstruct them or buy new cars is now necessary. The money for petroleum investigations is necessary because of the large direct interest of the United States in reserved petroleum-bearing lands and its indirect interest as guardian of the Indian lands. Within the year an unexpected burden was placed upon the Bureau when it was called upon to find a way to permit opening certain oil lands in Oklahoma without waste of the gas in the overlying sands. This was successfully accomplished, and a waste amounting to millions of cubic feet per day was stopped. In California large areas of presumably oil-bearing land are held for future use of the Navy and other branches of the Government service. The Geological Survey selected the lands and they are presumably well chosen. At the same time, there is no adequate knowledge of the probable effect on these lands of development on railroad and other tracts that exist within their limits, and introduction of water into the oil-sands by careless drillers may ruin the Government reserve. It is proposed to study the whole situation carefully to protect the Government's interest. At the same time, it is hoped that technical information of value to oil companies in general may be developed. In this connection the Bureau of Mines has made the following statement:

"In 1911 the total value of the petroleum produced in this country was \$134,044,752; that of the natural gas usefully produced was \$74,127,534. The magnitude of the petroleum industry, the increasing value of petroleum and natural gas as fuel, and the rapid decline of the yield from many fields emphasize the need of conducting inquiries concerning the mining, treatment, and utilization of petroleum and natural gas, with a view to economical and efficient development of these resources, as well as inquiries into the economic conditions that have developed in the oil and gas industries, with a view to the determination of the factors governing production and the means whereby supplies of oil and gas, especially those on public lands or on lands controlled by the Government, can be utilized to best advantage in promoting the public welfare. As illustrating the need for inquiries and investigations concerning petroleum and natural gas, with a view to economic development, it is pertinent to note the following extract from a recent report received by the Bureau of Mines regarding the Cushing field of Oklahoma: 'The maximum yield of oil from the Cushing field has never reached 30,000 bbl. per day. For a long period it has been considerably less than 20,000 bbl. per day. The average value of oil at the highest market quotation probably is below \$20,000 per day. During this time there has been wasting from drilling wells not less than 100,000,000 cu. ft. of gas, while the waste from flowing wells is perhaps in excess of 200,000,000 cu. ft., making a total daily waste of 300,000,000 cu. ft., which at the domestic rate of 25c. per thousand, would be \$75,000 per day in fuel, or a matter of perhaps \$20,000 per day to the oil producer. It is not only possible to conserve this gas, but it also is possible in many cases to so manage the wells that they can furnish oil without allowing the gas to escape.

The main purpose of the oil producer is to get the oil and let the gas escape.' There are other fields in the United States where enormous daily waste of gas occurs. Practically all of the oil purchased by the different branches of the service of the United States has been tested by the Bureau of Mines. This is particularly true of tests for the Navy Department, these purchases amounting during the past year to about 21,000,000 gal. of oil."

The proposed increase of \$20,000 in the appropriation for mineral mining investigations is made necessary by the demand for work in the Western states especially. The Bureau has recently issued excellent papers dealing with 'Safety in Tunneling,' written by D. W. Brunton and John A. Davis; 'Mine Accident Prevention at Lake Superior Iron Mines,' by Dwight E. Woodbridge; 'First-Aid Instructions for Miners,' by Messrs. Glasgow, Randenbush, and Roberts; 'Possible Causes of the Decline of Oil Wells,' by L. G. Huntley; and similar subjects. It is to expand the work upon which such reports is based that the money is asked. The detailed estimates are as follows:

General expenses	\$ 70,000
Mine accidents	347,000
Mine-rescue cars and stations	30,000
Equipment of testing plant	10,000
Testing fuels	135,000
Mineral mining investigation	120,000
Petroleum investigation	30,000
Inspection in Alaska	7,000
Library	2,000
Lands and leases for cars	1,000
Total	\$752,000

Those interested in Alaskan problems are distinctly hopeful of some legislation at this session of Congress. The strong endorsement given by the President to the project for building government railroad lines in the territory is felt to insure some action. There is also hope that a beginning at least will be made in the task of revising the mining law. Probably this will take the form of an attempt to clear up the situation regarding petroleum lands. J. E. Raker, of California, has become interested and has been collecting data and opinions from the Geological Survey and other sources of information.

KALGOORLIE, WESTERN AUSTRALIA

GWALIA CONSOLS, LANCEFIELD, AND GREAT VICTORIA MINES.—FIRE ASSAYING UNRELIABLE FOR GOLD.—BETTER DEVELOPMENTS AT THE VICTORIOUS AND HORSE-SHOE.—GEOLOGY OF KALGOORLIE.—THE CHAFFERS MINE.

Owing to the final collapse of Ben Howe's volatilizing process, the directors of the Gwalia Consols and Lancefield mining companies have decided to go into liquidation and abandon the mines. The Gwalia Consols mine has produced \$2,200,000 from 270,000 tons, and the Lancefield \$4,150,000 from 540,000 tons, and neither has paid a dividend. Both mines proved unprofitable in the sulphide zone, the former chiefly on account of antimony, and the latter on account of graphite and arsenical pyrite. The lode in the Gwalia Consols is 40 ft. and in the Lancefield 25 ft. wide, and the grade is higher in the sulphide than in the oxidized zone, but cannot be treated at a profit. The Gwalia Consols company has lost \$162,500 in cash working capital, and the Lancefield \$412,500, and both concerns are in debt, with useless machinery, building, and stores as their assets. The situation of both concerns is certainly unfortunate, and it is not for the want of faith by shareholders and directors, or lack of good mining or metallurgical ability that hope has been abandoned.

Bewick, Moreing & Co. have taken a sampling option on the Great Victoria mine, near Southern Cross, on behalf of the Mountain Queen company. The Great Victoria was last year under option to the Great Boulder Proprietary Co., but was rejected after several months of development and prospecting. The mine is situated 12 miles south of the Mountain Queen, and, as the oxidized ore in the latter is nearly depleted and the value of the sulphide is doubtful, a new property is being looked for. The Mountain Queen

company owns the Transvaal mine, whose ore is heavily impregnated with arsenical pyrite, and a process for its treatment will probably be hard to devise.

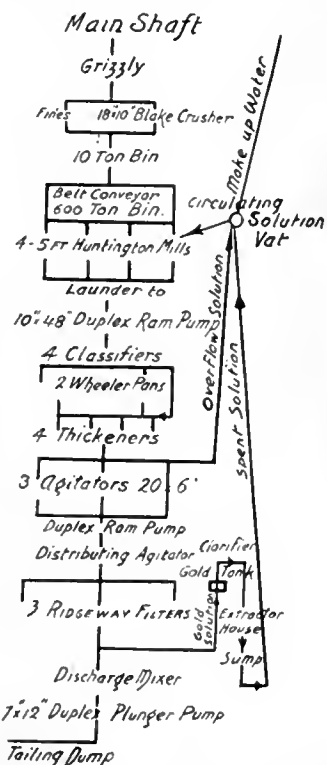

The Federal Ore Co., of Victoria, the owners of the I. H. Niemann patent process for treatment of selenite ores, has just treated a test shipment from the Broken Hill Gold & Copper Co.'s mine, returning 4.2 oz. gold per ton, leaving 6% copper in the residue. It is alleged that similar ore previously treated at Footscray, near Melbourne, yielded only \$5.36 and at Bendigo \$4 gold per ton. Mr. Niemann states that selenium is as universally present in ores as sulphur, and volatilizes the gold, and consequently that even fire-assays are unreliable. This is important if true. Incidentally the cost of the Niemann process is said to be very little more than milling and the results surprisingly high.

The position of the Victorious mine at Ora Banda is improving, as the last 45 ft. driven east is in high-grade ore containing free gold and telluride, showing occasional high assays. The comparative gold content of the east drifts at two levels is as follows: No. 4, from 1 to 190 ft., \$43.82, from 190 to 255 ft. \$3.02; No. 5, from 1 to 27 ft. \$2.16, 27 to 138 ft. \$14.28, 138 to 220 ft. \$4.56, and from 220 to 265 ft. \$25.74 per ton. The station at No. 6 level has been started and cross-cutting for the lode will soon begin. If this level warrants it, Edwards roasting furnaces and

developing so well of late that before long the returns and profits should show a substantial advance and place the mine at the head of the producers. Not only is No. 4 lode on the boundary of the Great Boulder mine opening splendidly, but No. 2 and 3 lodes, which have hitherto yielded over 90% of the ore treated, are improving toward the south, where they were quite barren in the upper levels.

Malcolm Maclaren has not yet returned from Queensland to inspect the Associated. His report to the directors of the Kalgurli has, however, been published, and in it he states that the lodes having passed out of the quartz-dolerite into the underlying calc-schist, at a depth of 1750 ft., are barren, and likely to remain so. This was described in this journal of November 8, 1913. According to Mr. Maclaren, five other important mines are in the same predicament, besides several smaller mines. In fact, a calc-schist band, coming in from the east, has cut off all profitable ore. The western contact of the quartz-dolerite with the calc-schist is just outside the Ivanhoe western boundary, and this accounts for the western mines being barren near the surface. Mr. Maclaren argues that when the calc-schist has been left behind, and the quartz-dolerite entered, new and profitable ore-shoots will probably be found. On his recommendation, the Ivanhoe company, which holds a large area of ground on the west, intends diamond-drilling to test the ground at a depth of 2000 to 3000 ft. If his theory proves correct, a fresh lease of life will be given to the district on the west of the 'Golden Mile.' He states "that it is unsound mining business to sink deeper in search of ore-bodies that both the indications present and a wide experience of similar conditions combine in asserting to be non-existent." In spite of this advice, prospecting in the condemned area is still being continued, and the Lake View Consols management reports rich ore opened at a depth of 2100 ft. This mine is on the same line as the Kalgurli.

Since the reconstruction of the Chaffers company the manager has been working at the No. 16, and has now started at the No. 15 level, although the advice of John Morgan, of the South Kalgurli, to the directors of the Chaffers company 18 months ago, was "to explore further your mine to a greater depth, as the latest discoveries in the Golden Horse-Shoe mine prove that profitable zones exist in the deeper ground." At the time of Mr. Morgan's report, cross-cuts at No. 15, 16, 18, and 20 levels had proved that the Golden Horse-Shoe's No. 2, 3, and 4 lodes were unprofitable at these depths, and since then the cross-cuts at No. 16 level have been extended nearly 600 ft. west. At 427 ft., the west branch of No. 3 lode was cut, and followed south 150 ft. in ore assaying \$28.32 per ton, and the face is within 70 ft. of the Hannan's Star boundary. Lode No. 4, Horse-Shoe No. 1, was cut 567 ft. west of the drift on lode No. 1, Horse-Shoe No. 4, and this lode has been driven on 326 ft. in ore assaying \$6.96 per ton. No cross-cuts in any level either above or below have been extended nearly so far west, so that no connections can be made to secure ventilation. Nothing new has been heard of the projected treatment plant.

FLOW-SHEET OF VICTORIOUS MILL. THIS PLANT TREATS 8000 TONS OF ORE MONTHLY AT A COST OF \$1.20 PER TON.

Krupp ball-mills will be purchased to replace the present Huntington mills. A peculiarity of the No. 5 level is that the ore is alternately oxidized and sulphide, and that where the ore is soft and oxidized the gold content is poor, and where it is hard sulphide it is rich in free gold and telluride. The next level will probably be all in sulphide ore. No winzes have been started below the fifth level yet. The shaft is quite dry and no water is found below this level. The future of the Ora Banda district depends on the next level of the Victorious, as the oxide ore in all of the mines has been proved by the government mill to be too low grade to make profitable properties.

The Golden Horse-Shoe Estates Co. has declared a dividend of \$1 per share, or \$300,000, which was rather unexpected. The Company started on January 1 with a credit balance of \$178,000, and has since made a profit of \$156,000. It, however, paid off \$31,500 debentures in May, and has to redeem another \$31,000 in November, besides paying the interest on the 375,000 debentures outstanding and redeemable within the next six years. However, the mine has been

BAJA CALIFORNIA

PROGRESS IN SAN ANTONIO DISTRICT.—IMPROVEMENTS AT THE CIA. METALURGICA DE LA BAJA CALIFORNIA.—THE WEST MEXICO MINES COMPANY.

The mining industry of the San Antonio district is more active than it has been for some time, as is evidenced by the new work and the number of new denouncements. The combination of the Progreso Mining Co. with the Cia. Metalurgica de la Baja California, has made a great improvement as to output, and when the new power-plant of 400 hp. is completed, the results will be excellent. The power plant includes suction gas-engines and electric generators. This power will be distributed to the various properties of the Company, to drive hoists, pumps, and the old plant at Triunfo. This Company has title to many properties, some of which are big producers. Fernando Castanier is general manager. The operations of the San Juanes Reduction Co. are second in importance in this district. The big roasters are now running at capacity, and, besides cyaniding the roasted product, the Company

is treating a quantity of oxidized ore. The mines of this Company are reported in good condition, and the ore reserves are large. At the present time the Parral mine is producing the greater portion of the sulphide ore for the roasters. This ore is being successfully hauled from the mine to the plant by a 5-ton Pierce-Arrow truck. The Hardinge mill that was installed to regrind the oversize from the rolls is proving a success. Two large masonry tanks for leaching have been added to increase the capacity of the plant. Paul Knappe is the manager.

The addition of concentrators to the West Mexico Mines Co.'s mill will greatly improve the equipment. The Company is now awaiting the arrival of a separator and two concentrating tables to resume operations. The principal mine of the Company, called the San Lorenzo, is opening up in fine shape and a new find has been made in this property of a large orebody carrying over 2 oz. of gold per ton and some silver.

The properties belonging to the Brazilar y Anexas company are being worked under the supervision of Frank Lawrance. During the month of September a splendid shipment of oxidized ore was made from the Gausabe mine, which is one of three properties owned by the Company. Up to date over 3500 tons of ore, worth \$50 per ton, has been treated, and all of this came from the Guasabe property. This mine also has a good grade lead-silver ore, shipment of which has been made to the Selby smelter.

There are several small operators in the San Antonio district at present, and many good prospects are being developed. One of the most needed and necessary requirements for this district is an up-to-date reduction plant for custom work. There is an abundance of ore, but the great difficulty is to get it treated.

NEW YORK

MINE TAXATION.—SMELTER SITUATION IN MEXICO.—GUGGENHEIM EXPLORATION.

It is a curious fact that important events seem to attract very little attention sometimes, and an instance of this is seen in the little comment evoked by the decision regarding mine taxation rendered on December 1 by the Supreme Court of the United States. When the United States began to tax the incomes of corporations a good deal of protest was made by some mining companies on the score that the difference between their gross returns and expenses does not represent net income, but is in large part a return of capital, since a mine is worked out in a comparatively short time. This theory so appealed to some companies that by using a suitable unit in computing the depreciation in the value of the mine per ton of ore extracted they were able to show no regular income. The Stratton's Independence instituted a test case, which has gone its way to the Supreme Court of the United States. This court held that the corporation tax law applies to mining companies, the proceeds from the ore mined are income within the meaning of the law, and the value of the ore in place may not be deducted from these proceeds in computing the income of the company. Mining companies are already taxed somewhat heavier in proportion than other forms of property, and there seems a certain degree of justice in the contention that the net proceeds of a mine do not represent the same sort of income as that from a railroad, for example. In some of the Western states, notably Arizona, tax laws have recently been enacted which assess mines at a very high valuation. It would seem as though the general subject of mine taxation needs a thorough overhauling.

Rumors were floating around last week that the American Smelting & Refining Co. had given orders to shut down all its Mexican plants. The rumor was baseless, but there was a certain amount of grim humor in it, for as a matter of fact only the smelter at Aguascalientes is now in operation, and that only at half capacity. The others have been compelled to stop because of interruption of communications and the disturbed conditions generally, but it is hoped that some of them will be able to start again at an early date. The earnings of the Mexican companies have been remarkably good, considering the difficulties of the past year. The Guggenheim Exploration has declared an extra dividend of

2%, bringing this year's total up to 37½%. Last year the Company earned 15.7% on its outstanding stock. In 1912 the Company disposed of 110,000 shares of its American Smelters Securities preferred 'A' stock, and \$1,500,000, par value of its American Smelters Securities 6% bonds, and bought 65,246 shares of Yukon Gold stock, 69,500 shares of American Smelting & Refining, 97,750 shares of Chino Copper Co., and 121,200 shares of Ray Consolidated. As the result of placing Chino on a \$3 per annum dividend basis and Ray Consolidated on \$1.50 per annum dividend basis, the Guggenheim Exploration earnings from investment are now at a rate greater than last year's. The annual report for the year ended December 31, 1912, showed the Company with no bills or accounts payable and cash and demand loans of \$10,303,299.

TORONTO, CANADA

ROYALTIES PAID BY COBALT MINES.—MOND NICKEL CO.'S NEW MINE.—NEW COMPANIES AT PORCUPINE.—JUPITER COM-

During the past year the royalties collected from the Cobalt mines by the Ontario Government amounted to \$250,145. The following table shows the total paid by the mines up to October 1912 and that paid for the year:

	Royalties for 1912.	Total to date.
O'Brien	\$72,071	\$668,376
Crown Reserve	136,180	611,991
Hudson Bay	36,759	245,270
Chambers-Ferland	26,260
Hargraves	1,200
Waldman	777
Wiandoah	123,123	1,422
Provincial	5,012	6,735
	\$250,145	\$1,562,031

The decreased earnings of several companies have influenced the Government to make a considerable reduction in the amount of royalties to be paid in future. The royalty paid by the O'Brien was reduced from 25% of the gross value of the ore at the collar of the shaft, to 15% of the net profits. Should other bonanzas be opened in future workings, the Government retains the power to restore the former rate. The Hudson Bay company pays 15% of the gross value of the output, but an allowance has been made to cover the cost of concentrating. In the case of the Chambers-Ferland and Hargraves, the royalty, which was originally 25% of the gross value, has been abolished entirely; but the right is reserved to impose a royalty not exceeding 15% of the net profits.

One of the most important deals in the Sudbury nickel range was recently closed when the Mond Nickel Co. purchased the Big Levack property for a price of approximately \$650,000. The property was under option for some time, and the six diamond-drills which were at work are stated to have proved 2,000,000 tons of ore. The property comprises 1600 acres, and was first staked in 1882. A few years ago, the Mond company had an option on it at a much lower price.

The advent of the West Australian Gold Mines, Ltd., which is one of the subsidiary companies of Erlich & Co., in the Porcupine district, is responsible for a greater interest being taken in the surrounding properties. The West Australian company has taken an option on the North Thompson claim which adjoins the Hollinger on the south, and the McEnaney on the east, and it expects to get the extension of the No. 44 vein from the Hollinger, and also to get the dip of the Porcupine Crown vein. The Company already has two diamond-drills at work and has started sinking a shaft. The deal for the North Thompson lot, which was purchased from G. Von Polenz, and Norman Fisher, manager of the Temiskaming mine, was as follows: The West Australian company will form a company with a capitalization of 1,000,000 shares, par value \$1, \$525,000 will be left in the treasury, while vendors get \$83,500 in cash and 150,000 shares of stock. In order to provide money for development and equipment, the Western Australian company will take treasury shares at par.

General Mining News

ALASKA

CORDOVA

During the season of 1913 the Valdez Creek Placer Mines Co. operated on a bank of gravel 110 ft. high and 200 ft. wide, and the clean-up gave an average of \$1.59 per cubic yard in that part above the old workings. A ditch and pipe-line was completed during the year, and another long pipe to give an additional capacity of 5000 cu. yd. per 24 hours is being planned by the Company. On Lucky gulch, 7 miles above this property, there was recovered about \$3000, some of the gold being in the form of nuggets worth from \$5 to \$60. A No. 4 Keystone and an Empire drill will be sent in by the Company at an early date to prospect the ground near here.

FAIRBANKS

With the proposed new mill on the Fish creek property there will be 14 stamp-mills in the Fairbanks district, and the miners expect that most of these will be running full time next summer. The mills which are already constructed are: Hudson brothers, a 2-stamp Nissen mill, on 4 Above, Ester creek; Soo mine, one small 3-stamp and one large 2-stamp mill, situated on upper Dome creek; Rainbow mine, Straub rapid stamp-mill; Furstenau property, a Little Giant stamp-mill, at the head of Fairbanks creek; Rexall mine, 2-stamp Hendy, situated at the head of Wolf creek; Chatham Mining Co., 4-stamp Hendy, situated on Chatham creek; Willis' property, 5-stamp Hendy, situated near Chatham Mining Co.'s mill; Rhoads-Hall mine, 5-stamp Hendy mill, situated on Bedrock creek; Chena mill, 10-stamp Hendy, at Chena; Fairbanks test mill, situated on Garden island; Newsboy, 5-stamp Hendy, head of Cleary creek; Tolovana, 2-stamp Nissen, Willow creek. The Newsboy crushed 400 tons of ore in October. A new scraper will be installed at the Ryan & Lundberg ground on 4 Below, Fairbanks creek, where prospecting has shown an average of \$1 to \$1.50 per square foot of bedrock. On 2 Below, operators are preparing for next season.

JUNEAU

During October the two 120-stamp mills at the Alaska United crushed a total of 38,906 tons of ore, yielding \$74,488 by amalgamation and treatment of 848 tons of concentrate. The estimated profit was \$18,062. Development in the Ready Bullion mine covered 194 ft., and 482 ft. in the 700-ft. claim, the stocks of broken ore decreasing 1700 and increasing 1845 tons respectively.

SHUSHANA

According to John E. Barrett, an old Alaskan prospector, Shushana looks as though it might make a big camp. James Ground produced \$27,000 out of 39 box lengths, 12 by 14 ft. each, and it is only 3½ ft. to bedrock on this claim. This property is on El Dorado creek, the McClellan claim has richer ground than this on Bonanza creek. A. C. Baldwin, of the Alaska boundary survey, got \$5.50 in three pans on McClellan's claim. The new winter sled road is now completed and staked over the Nizina and Shushana glaciers. Horses have gone through with 'double-enders' over the glaciers, and wagons are going from here to the Nizina glacier with 3600 to the load. Travelers are coming out from Shushana to McCarthy in 2½ days, and as soon as snow falls the trip will be made with dog team in 1½ days and with horses and loads in 4 days. The route is safe from snow-slides, as they have no side-hills to go along. Other prospectors have recently arrived at Cordova over the glacier trail and report that generally it is in good condition. There are at present 300 people in the camp, 17 of whom are women. Five steam boilers had arrived from Snag river, and from 300 to 400 men are waiting on the other side of the boundary line, waiting the freeze-up. Beef is selling at 65c. per pound. A full account of work done in locating and marking the new trail was given on November 25 by George C. Hazlet, who is in charge of the work, to the Cordova Chamber of Commerce. About 15

outfits, ranging from 400 to 16,000 lb., have passed over the glacier since November 1. The distance from McCarthy to the placer field is not over 75 miles. There are road-houses for accommodation. When the rivers freeze, the cost of freighting should not be over 10 or 12c. per pound. A number of men are going in poorly equipped, and the U. S. Government should do as the Canadian authorities, that is, station a police officer at each starting point to see that every man is properly supplied before he leaves.

ARIZONA

MARICOPA COUNTY

Between January 1 and October 1, 24,354 tons of ore was mined and milled at the Vulture. The average gold content of this ore was \$20.54 per ton, and an average recovery of \$17.40 was made. The production of bullion for that period was \$276,772, and from concentrate \$152,643, a total of \$429,416 for the nine months. Under previous managements the Vulture produced over \$2,000,000.

PINAL COUNTY

The three-compartment shaft on the property of the Calumet & Arizona Mining Co. at Superior has been completed to the seventh level, which will enable the Company to remove the ore in a more economical manner, and also handle a larger tonnage. The large pumps recently installed handle the water from the mine with ease, making working conditions better than heretofore. Seventy-five men are now employed by the Company.

YAVAPAI COUNTY

Good sulphide ore has been opened on the 300-ft. level of the Copper Queen mine, near Stoddard. An option has been taken on the Independence, near Kirkland, by Brooklyn men. Five 6-mule teams are hauling ore from the Commercial mine, in Copper basin, to Skull Valley station, and then by rail to the Copper Queen smelter at Douglas. Fifty tons per day of silicious ore, with 4% copper, from this mine is to be sent to the United Verde smelter at Jerome. At the Henrietta, 10 men are mining \$40 ore, and more men will be engaged soon. The new electric motors have been installed.

YUMA COUNTY

A receiver has been appointed for the Swansea Consolidated Gold & Copper Co., whose mine and smelter are in the northern part of the county. Twelve miles east of Ehrenberg is a placer formation from 5 to 16 ft. deep, proved by numerous drill-holes to contain gold. A Colorado syndicate, headed by E. L. Burcamp, will treat this by a scraping system, which requires little water.

CALIFORNIA

AMADOR COUNTY

The management of the Plymouth mine has been authorized from London to proceed with development, which will include sinking the shaft from 1500 to 1800 ft., and then preparing for stoping the ore opened by winzes below the 1500-ft. level. A 300-ton mill is now being designed by Gelasio Caetanl. Argument in the suit between the Kennedy Extension and Argonaut companies at Jackson, which was to have been started on December 8, has been postponed till January 8. At the Central Eureka, two miles from Jackson, development has opened a promising vein which is an extension of the old shoot, that yielded good ore in past years. A. Millar and W. H. Storms, of San Francisco, arrived in Sutter Creek recently to inspect the West Eureka mine. Mr. Millar has a large interest in a company that was recently formed to take over this property on a bond from local owners. A new shaft is to be sunk at an early date.

BUTTE COUNTY

Three dredges of the Oroville Dredging Co. yielded \$4849 during the week ended November 1. A circular issued in London, by the Company, states that arrangements have been made for an extension of the time for the repayment of the loan from the Gold Fields American Development Co., and it is proposed to resume payment of dividends at the end of December at the rate of 10% per annum, the first quarter to be paid in February 1914. The remaining

indebtedness will probably be liquidated during the first quarter of the coming year. Profits from the Pato dredge, Colombia, returns of which are given on another page of this issue, have been excellent, and are relied on to justify the proposals given.

CALAVERAS COUNTY

Two St. Louis men who got control of the Reiner Mining Co. last week have not paid an assessment of 15c. per share on their holdings, and are seeking to prevent the sale on the grounds that this is not legal. Details of the position of this Company were given in this journal of August 9, 1913.

INYO COUNTY

Well-boring machinery is being delivered in the Panamint valley to test the potash claims under option to Eastern people. W. C. Bass is in charge for the Smith-Emery Co., of Los Angeles, who are to do the work by contract. He expects to sink 600-ft. holes in different parts of the valley.

LOS ANGELES COUNTY

The Los Angeles Chamber of Mines and Oil on December 11 exhibited at the German building the S. W. Clawson collection of Bisbee copper ores. These magnificent speci-

MUSEUM OF LOS ANGELES CHAMBER OF MINES.

mens have been purchased for the mining exhibit by Thomas Thorkildsen and J. O. Royer, and the specially designed cabinet was secured through the generosity of J. Ross Clark and Seeley W. Mudd. The collection is an object of unusual interest and of exquisite beauty.

SHASTA COUNTY

On January 5, 1914, the Hazel Gold Mining Co., owning the Gladstone mine near Kennett, will pay its twelfth dividend for 1912, equal to \$108,000 for the year, making a total of \$1,008,000 to date. In a few weeks a new electric hoist will be installed, and the shaft sunk deeper. At the Field process plant being erected near Redding rapid progress is being made. Rich copper ore has been opened in the Delta Consolidated, near Delta.

SONOMA COUNTY

The railroad being built by the Sonoma Magnesite Co. from its mines to the station at Watson, and there joining the Northwestern Pacific railroad, is now nearing completion, having only to go about 3½ miles. This Company is said to own the largest deposit of magnesite in the United States, and expects to make its first shipment to San Francisco about May 1, 1914.

TUOLUMNE COUNTY

A bond and option to purchase the Clio mine for \$150,000 has been given Robert Grauer by the Oro Mining Co. The first payment of \$5000 is to be made within one year and the balance within five years. The Clio mine is situated near Jacksonville and is looked on as a good property, but its development has been retarded by mismanagement and litigation in the past. Twelve men are working at the Santa Vsabel under C. E. Shafer.

COLORADO

Heavy snowstorms fell all over the state during the end of last week, and 15 ft. was piled up in the Cripple Creek district.

EAGLE COUNTY

There are 75 men employed in the Brush Creek district.

The Lady Belle is shipping 16 to 20 tons of ore per day. The winze is down 70 ft., where a small vein was cut. Assays from ore in the North Dakota have been as high as 955 oz. silver per ton. Lady Belle No. 4 has been leased and an adit is being driven. Twenty-ounce ore has been opened in the Little Salem.

LAKE COUNTY (LEADVILLE)

In Lackawanna gulch, the Lackawanna Belle Gold Mining Co.'s mine is developing in fine shape, and rich ore has been opened in No. 1 ore-shoot. A cross-cut adit is to be driven in 600 ft. from Lake creek. In the spring a small mill will be erected. Akron, Ohio, people are interested in the property. At the New Monarch there are 22 different sets of lessees working, and most of them are doing well. The orebody in what is known as No. 5 stope of No. 2 adit of the Mt. Champion, is now 25 ft. wide. Of this, 5 ft. is smelting and the balance milling ore. This is the largest shoot opened in this property. Mr. Smith, the manager, has decided to run all of the ore through the mill, thereby saving the heavy cost of transportation and increasing the value of the concentrate.

LAS ANIMAS COUNTY

It is reported that the United Mine Workers officials have decided to submit to Governor Ammon's proposal to submit the question of a settlement to the strikers for a referendum vote. The suggestion does not include recognition of the union nor an increase in the wage scale, but is the one which has already been accepted by the operators.

TELLER COUNTY (CRIPPLE CREEK)

The accident in the Golden Cycle mine, referred to in the last issue of this journal, occurred on La Bella vein, about 600 ft. north of the main shaft, and the slide is said to have affected a mass 200 ft. wide and 1000 ft. deep. Thomas Henahan and James Stewart, state commission of mines and mines inspector, respectively, have inspected the mine and are assisting rescue operations. Wonderful results have been made by the men at this work, but there is little hope for the entombed men.

THE SAN JUAN

Production from the Rico property is being made from two faces of ores at the present time, shipments having been curtailed through lack of hauling facilities to the railroad. The Company has on hand and ready for shipment 6 cars of carbonate ore, 6 cars of copper rock, which will be consigned to a local smelting plant, and 15 cars of copper ore, which will be shipped to the Ouray smelter. In addition to this, there are being loaded one car of iron ore and one car of zinc ore. Shipments for December will aggregate at least 40 cars, with the probability that they will be greater than this. Conditions at the mine are reported to be satisfactory.

Rico ore shipments for October were as follows:

Mine.	Ore.	Cars.
Rico-Wellington	copper ore	29
Rico-Wellington	zinc concentrate	7
Rico-Wellington	lead concentrate	4
Rico-Argentine	copper ore	19
Rico-Argentine	iron ore	1
Rico-Argentine	silver-lead	4
Rico Mining Co.....	lead concentrate	5
Rico Mining Co.....	zinc concentrate	9
Carpathia Mining Co.....	silver-lead	1
L. Habermann	copper ore	1
Custis & Nixon	silver-lead	2
Hays & Krise.....	silver-lead	1
Total		83

Fire destroyed the tramway, terminals, ore-bins, stables, and all other buildings at the Sunnyside mine, near Silver-ton, on December 1. The damage is estimated at \$50,000, and 120 men are without employment for the time being.

IDAHO

IDAHO COUNTY

A bond has been taken on the Yellow Pine group of claims on the south fork of the Clearwater river, 45 miles from Stites, by Norman Hooper and Ben Braham, of Kellogg.

and H. J. Rice, of Mullan. A 5-stamp mill is to be erected to treat the gold ores opened.

MICHIGAN

HOUGHTON COUNTY

The eight-hour day for miners and stamp-mill employees went into effect on December 1 at all the mines of the copper district. The scale of wages on the new basis will be \$3 per shift worked.

MISSOURI

ST. FRANCIS COUNTY

Details of the work of the Myers-Whaley shoveling machine operated in No. 11 mine of the Federal Lead Co., at Flat River, are supplied by the manager, H. A. Guess, as follows: The machine operates with two men, who sledge up the big rock, one operator, and one car-leveler. In addition, there is mule haulage to and from the machine, but that is really tramping and not loading. For October the machine shoveled 6962 tons and had delays as follows: moving machine, 648 minutes; off track, 895; repairs, 3220; total, 79 hours 23 minutes. These were the delays inherent in the machine. In addition there were delays incident to the mining operations as follows: cleaning and repairing track, 1156 minutes; breaking rock, 2130; scaling bluffs by safety miners, 1108; block out, 279; shifting cars, 3210; miscellaneous, 357; total, 8240 minutes, or 137 hours 20 minutes. There were 27 working days in October of two 8-hour shifts, or 54 shifts in all, so net running time for the shovel was 217 hours 15 minutes. Repairs are variable, but will average perhaps \$60 per month, including labor and material. At the National mine the same machine has been given up as too costly. In low stopes where it cannot work to capacity it proves uneconomical.

MONTANA

MISSOULA COUNTY

After years of litigation, the Amador Copper & Gold Mining Co. is again operating its mine near Iron Mountain. A pump was kept working in the mine all the time and the flume kept in repair. The railway connecting with the Northern Pacific line cost over \$5000 to put in order. A locomotive, constructed out of a 50-hp. gasoline engine mounted on a truck, and driving it by means of a chain belt, conveys the ore cars over this 10.5 miles of track. Several shipments of 12 to 15% copper ore have been sent to Tacoma since October. This ore comes from the 400-ft. level of the mine. On the dump is 20,000 tons of ore, and a mill will probably be erected to treat this.

NEVADA

ELKO COUNTY

A lease and bond has been acquired by John C. Yore, acting for San Francisco people, on the Nevada-Anaconda Copper Co.'s claim, 20 miles from Elko, for \$60,000. About \$7000 has been spent on development in driving adits and other work. Ore shipments have netted up to \$60 per ton, and that mined by the new people calls for a royalty of 15 to 20%. A shaft is being sunk on 8 ft. of ore. At the Carlin-Nevada claim adjoining, prospecting is under way, and surface ores have assayed from \$3 to \$38 per ton in lead and silver. Eighteen inches of \$40 ore has been opened in the Diamond claim. The Sunrise group is opening in a promising way. In the Old Bullion district, near Elko, lessees are shipping rich ore from a 10-ft. vein to the United States Smelting company's plant in Utah. Sixty men are employed. In the Dolly Varden district there will probably be increased activity early next year, although at present a lot of development is under way.

ESMERALDA COUNTY

The estimated production of the Goldfield Consolidated Mines Co. for November is as follows:

Ore mined, tons	28,927
Gross value recovered	\$348,000
Operating expenses	180,000
Net realization	168,000

Development at the Blue Bull continues on the 500 and 700-ft. levels, and good assays have come from ore on the former level, containing gold, silver, and copper. Fifty tons of ore per day is being sent to the Belmont mill at Millers

from the Florence mine, a distance of about 37 miles. The total cost of transport and treatment is \$5.50 per ton. The Pioneer company has now an ample supply of water, supplied from springs two miles from the mine. The mill is again in operation.

HUMBOLDT COUNTY

Near Imlay, the Imlay Mining Co. has opened a 12-ft. vein in the Judge claim, assaying 137 oz. silver and a little gold. The Company has made an assessment for further work.

At the Hines-Baldwin lease, at National, a well defined vein $3\frac{1}{2}$ ft. wide has been opened beyond the fault. An adit will probably be driven on the west side of the Shilo group of claims. The National Mines Co. is working to the south in its lower levels, and the orebodies are increasing in size with depth. This Company is running its mill, which is situated at the portal of the No. 5 main adit. The Charleston National Mines Co. has started to cross-cut from its main shaft to the west, where it will cut the vein at about 300 ft. vertical depth. The main shaft is also being sunk at the same time. Considerable work is under way at the Charleston Hill, Indian National, and at Auto Hill properties.

LYON COUNTY

The Nevada-Douglas Copper Co. reports the following results of operations in October:

Ore shipped to smelter, tons.....	4,529
Average copper content, per cent.....	6.44
Revenue	\$55,112
Operating expenses	18,836
Taxes, depreciation, leaching expenses, etc.....	7,733
Net income	28,543

NYE COUNTY

After working for eight months, and crushing 18,294 tons of ore yielding gold worth \$67,190, the Manhattan Big Four 10-stamp mill has been shut down indefinitely. During the period from March to October the value of the ore decreased from \$8.32 to \$2.25 per ton, and it is now proposed to acquire adjoining property. Owing to defects in No. 2 battery foundation, an insecure rock-crusher, and small water supply, the plant's capacity has been greatly reduced of late, although recovery has been good. D. R. Finlayson is superintendent. Experiments are being made on base ores from the White Caps and Manhattan Consolidated mines at Oakland, California. An electro-cyanide process is said to have given good results. For the 10 months of the current year the White Caps mine has produced 3570 tons valued at \$84,491, this being the largest yield at Manhattan. The initial mill run in the Manhattan Milling & Ore Co.'s 10-stamp mill, under the management of the operators of the Big Pine, Messrs. Mushett and Wittenberg, is under way. It is intended to treat ores from the Big Pine, Manhattan Dexter, Mayflower, and Gold Crater properties in this mill, the various properties being operated by Mushett and Wittenberg. Under the Brady management the mill treated 10,000 tons of ore of a gross value of \$100,000 during 1913.

At Tonopah, the north cross-cut on the 950-ft. level from the new main shaft of the Extension has opened the Murray vein, which shows good ore.

On the 850 and 750-ft. levels ore has been driven on for over 250 ft., where it is from 5 to 14 ft. wide. Good progress is being made with the electric tramway from the new shaft to the mill. The plant is treating 15 tons of ore per day. On January 1, 1914, the Belmont company will pay 25c. per share, amounting to \$375,000, and making a total of \$5,618,000 to date. November bullion shipments totaled 11.46 tons. In a drift from the winze below 1050 ft. in the North Star, rich ore has been opened. According to S. H. Brady, the West End mine is looking exceptionally well, especially on the 600-ft. level, and stopping above the 500-ft. level. A new hoist is being installed with a speed of 1000 ft. per minute in hoisting ore. Another 10 stamps and one tube-mill are to be added to the mill at once. The south cross-cut, on the 615-ft. level of the Montana, cut the A. B. K. vein where it was 4 ft. wide and assayed \$85 per ton. During the week ended December 6, mines at Tonopah produced 11,868 tons of ore valued at \$280,355.

STOREY COUNTY

Last week the Starrett pump in the old Con. Virginia winze, on the 2500-ft. level of the C. & C. pumping shaft, was started, and in a few hours lowered the water 23 ft. below the winze collar.

WHITE PINE COUNTY

Thomas F. Cole, president of the Giroux Consolidated, and a director of the Consolidated Copper Mines Co., is inspecting these properties at Ely.

CANADA

ONTARIO

There is now being hoisted through the various shafts in the Sudbury district about 4000 tons of ore per day. Half of this comes from the Canadian Copper Co., and 800 tons from the Moose Mountain iron mine, about thirty miles from Sudbury, but which is, nevertheless, tributary to this district. The British American Nickel Co. is sinking a 3-compartment shaft at the Murray mine, which is down 400 ft. The Gertrude, Whistle, and Elsie properties are ready for development. The Victoria mine of the Mond Nickel Co. is down 2000 ft., and the 'glory-hole' at the Creighton is 300 ft. deep. At the Froude, 64 houses are to be built for employees. The vertical and incline shafts are down 400 feet.

Work has commenced underground on the Drummond Fraction at Cobalt, the section of land and water bought jointly by the Kerr Lake and Crown Reserve companies from Earle and Fasken before the incorporation of the old Drummond and Cobalt Comet, later the Caribou Cobalt. The property is being worked as a separate unit and under separate mine management. Before Kerr lake was drained, nearly all the Drummond Fraction, of 7.75 acres, was under water. Since then a promising vein has been uncovered. Mark Little is mine superintendent.

At a meeting held at Cobalt on November 28 the following mines were represented: Dominion Reduction, York Ontario, Crown Reserve, Nipissing, McKinley-Darragh-Savage, Cobalt Townsite, City of Cobalt, Buffalo, Hudson Bay, Beaver, Trethewey, and Cobalt Lake. It was decided to post notices immediately relative to the new schedule of hours going into effect on January 1, in accordance with the new eight-hour day law passed at the last session of the Ontario Legislature.

During October the Buffalo Mines treated 6662 tons of ore yielding 135,457 oz. silver. Dividend No. 55, of 7%, was paid on November 15, making a total of \$2,507,000 to date. The township of Coleman has withdrawn opposition to draining Cobalt lake. Drifts at 100 and 200 ft. in the Tough-Oakes mine, at Karkland Lake, are still in high-grade ore, 230 and 110 ft., respectively, being opened.

During the four weeks ended November 4, the Hollinger, at Porcupine, treated 13,401 tons of ore yielding \$15.07 per ton with 96.1% recovery. The profit was \$124,495. There is 8 ft. of \$17 ore at the bottom of the winze below the 425-ft. level.

COLOMBIA

Returns from the Pato dredge of Oroville Dredging, Ltd., are as follows:

	Gravel treated, cu. yd.	Gross gold yield.
To October 21	239,492	\$140,617
Week of October 28	24,100	15,900
Week of November 4	26,370	17,500
Week of November 11	25,250	31,250
Total	315,212	\$205,267

These returns give an average of 65.12c. per cubic yard, or more than double the estimated average of the tested area, this being 31.31c. per yard. The last weekly output averaged \$1.23 from ground that one of the drill-holes gave only 34c. per yard.

MEXICO

HIDALGO

The fifth annual meeting of Santa Gertrudis Co., Ltd., was held in London on November 19, and results may be tabulated as follows:

Development, feet	17,000
Ore reserves at June 30, 1913:	
Positive and partly developed, tons	778,000
Probable, tons	269,000
Estimated profit from total reserves.....\$	4,700,000
Ore treated, tons	263,554
Metal recovery:	
Gold, ounces	21,800
Silver, ounces	4,243,000
Net profit, depreciation deducted	\$1,110,000
Dividends	1,060,000
Carried forward	38,000

The property is known to contain, besides the main vein, 11 other productive veins, six of which were discovered during the past fiscal year. On No. 16 and 17 levels, west of the San Francisco shaft, an ore-shoot 10 ft. wide

SANTA GERTRUDIS MILL.

and 150 ft. long, with limits undefined, has been opened. Development of No. 19 level was finished, showing a shoot of payable ore nearly 1635 ft. long, although it is narrower and of lower grade than on the level above. Since the end of the year, No. 20 level has been reached and driving started in ore. San Francisco No. 2 shaft is down 1760 ft., and new surface equipment installed, so that it is now convenient to produce 25,000 tons of ore per month, October showing 30,000 tons with a profit of \$105,000.

A cable to London on November 23 stated that, on No. 17 level the south cross-cut has passed through 21 ft. of \$47 ore per metric ton. The formation is unusual, and it has not been proved whether the shoot is the vein or merely locally mineralized rock.

JALISCO

The Mexican Development Co., of Peoria, Illinois, which is developing the Quelitlan copper property in the Autlan district of this state, 18 miles from the Pacific port of Chamela, has let a contract for the sinking of the double-compartment shaft an additional 100 ft. The shaft is now down 110 ft. A Knowles sinking pump has been installed. Three ore-shoots have been opened so far and contain 10% copper, \$10 to \$20 per ton in silver, and considerable zinc. Plans have been arranged for a smelter and zinc separation plant.

SONORA

It is reported at Douglas, Arizona, that interests allied with the Southern Pacific railroad have taken over the Lampazos mine, held by the Bank of Sonora, under mortgage by Lopez Bros. for about \$400,000. The property is 48 miles south of Moctezuma and 85 miles southeast of Nacoari.

Personal

BERTRAM HUNT is in London.
 J. H. LIDGERWOOD is in London.
 L. K. HOULTON has gone to Arizona.
 E. E. SOMERMEIR is in San Francisco.
 S. W. PARR is in San Francisco this week.
 MILNOR ROBERTS is at Kennett, California.
 T. J. ANDERSON is in New York from Nome.
 SAMUEL W. COHEN was in New York last week.
 B. BRITTON GOTTSBERGER has returned to Miami.
 LEO VON ROSENBERG is in the Ray district, Arizona.
 H. P. HENDERSON is now at 66 Broadway, New York.
 EDMUND JUESSEN has returned from western Arizona.
 W. H. ALDRIDGE is expected in New York December 10.
 THOMAS H. LEGGETT has been in San Francisco this week.
 C. S. HERZIG sailed for London on the *Lusitania* December 3.

F. DANVERS POWER was in New York and has gone to London.

WALTER CURRIE will go to London from Bulawayo, Rhodesia, in January.

RALPH ARNOLD is returning from Venezuela and will be in New York today.

S. E. BRETHERTON spent last week in Shasta county on professional business.

A. J. EVELAND will be in Colorado and Utah on professional work until the first of the year.

E. J. SCHRADER has been examining the property of the Brunswick Con. M. Co., near Emplre, Nevada.

G. B. LANTZ sailed last Thursday for the Philippines to accept a position with the Colorado Mining Company.

T. H. OXNAM, of Los Angeles, was in San Francisco this week attending the funeral of his brother, CHARLES OXNAM.

LEONARD A. BAXTER, of London, has gone to Northern Nigeria to take charge of the properties of the South Bukern company.

H. CLARKSON FLETCHER, of Johnson & Fletcher, Bulawayo, Rhodesia, is in London and expects to remain there about three months.

STANLEY C. SEARS, consulting mining engineering and metallurgist, has opened an office at 705 Walker Bank building, Salt Lake City.

ROBERT C. STICHT, general manager for the Mt. Lyell Mining & Railway Co., Tasmania, will leave Melbourne, Victoria, in January for an extended tour of the world.

R. H. RICHARDS has gone to Indianapolis in connection with the Wilfley table litigation. He recently gave the mining department of the Massachusetts Institute of Technology a hindered settling open-spigot classifier.

W. A. FARISH, Jr., has succeeded M. BROWN, of the firm of Miller & Brown, and will take an active part in the affairs of the new firm of chemists and metallurgists, which will be known as the Miller-Farish Co., with headquarters at 532 Commercial street, San Francisco.

Obituary

JOHN McMAHON, a former prominent mine operator of the San Juan district, Colorado, died in Los Angeles on November 16. He was born in Orange county, New York, and came in 1874 to Georgetown, Colorado, becoming associated with the Pelican-Dives mine. In 1876 he journeyed by horseback from Denver to Lake City, going by way of Cañon City, Salida, Poncho Pass, and Del Norte. In the fall of 1877 he undertook the management of the Aspen mine at Silverton and remained in charge until the following spring; from there he went to Leadville and returned to Lake City. He was appointed special deputy to take charge of the notorious criminal Packard in 1884 and shielded him from the hands of mobs bent upon lynching. At various times he was in charge of some of the famous producers of the San Juan district, including the Humboldt in 1902. He was an honest man in his dealings, was fearless in his duties, and was held in highest esteem by all.

Decisions Relating to Mining

FREE USE OF TIMBER ON MINERAL LANDS

A new set of instructions, under date of March 25, 1913, has been promulgated by the Secretary of the Interior with reference to the cutting of timber on public mineral lands. Anyone interested may read them in full in the advance pages of Volume 42, Land Decisions, page 30.

MINING COAL ON PROPERTY LINE—PENALTY

Where a statute provides a penalty of \$500 to be paid by any person mining coal within five feet of the property line of another, in order to recover this penalty in an action at law it is unnecessary for the plaintiff to prove that he suffered any damage if he is able to show that defendant has mined coal within the prohibited space.

Selvey v. Grafton Coal & Coke Co. (West Virginia), 79 Southeastern, 656. Sept. 23, 1913.

HOMESTEAD ENTRY OF MINERAL LAND

Where a homestead entryman made final proof and received a patent to his land after five years residence, and some eighteen months after receipt of patent made a coal lease thereon to prospectors who eventually developed a profitable coal mine on the property, the agricultural patent will not be canceled at the government's suit, in the absence of a showing of positive fraud on the part of the entryman, or the existence of such a state of facts as would have indicated reasonable probability, at the time final proof was made, that the land was more valuable for mineral than for other purposes.

United States v. Kostelak (Montana), 207 Federal, 447. August 4, 1913.

MINING LEASE—REMOVAL OF MACHINERY

A mining lease contained a covenant that if there were any arrearages in royalties, machinery placed on the land by the lessee should not be removed without the lessor's consent. The lessee assigned his lease and in the assignment stipulated that his assignee should not be bound by the terms of the foregoing covenant. It was held that the lessor, not being a party to the assignment, was not bound by this stipulation, and, royalties being in arrears, could enjoin the removal of machinery placed on the land.

Freeman v. New Jersey Portland Cement Co. (New York), 207 Federal, 699. Sept. 16, 1913.

CANCELLATION OF PATENT

On application for a patent for six mining claims adjoining each other and lying lengthwise along a river in a forest reservation, notice was sent by the register to the superintendent of the reservation, who caused an examination to be made, and as a result there was filed in the General Land Office a letter from the acting forester, enclosing reports from the state geologist and a forest ranger, and recommending that a patent be denied on the ground that the claims were held for water-power and not for mineral purposes. The report of the geologist was to the effect that the claims contained very little ore and were of no commercial value for mining purposes, but were very valuable for the water power thereon. Three weeks after the filing of such papers a patent was issued to the applicant. It appeared that no hearing was had upon the protest of the forester, probably because it erroneously stated that no patent for the claims to which it related had been applied for. Held that, if the facts on which it was based were established, they would constitute grounds for refusing a patent, and that whether it was not considered through inadvertence, or whether, through mistake of law, it was deemed insufficient, the United States was entitled to a cancellation of the patent, that such questions of fact might be determined by the land department.

United States v. Lavenson et al., 206 Federal, 755. June 13, 1913.

The Metal Markets

LOCAL METAL PRICES

San Francisco, December 11.

Antimony.....	10-10½c	Quicksilver (flask).....	840

Pig lead.....	4.2½-5.20c	Spelter.....	6½-6¾c

Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.

EASTERN METAL MARKETS.

(By wire from New York.)

NEW YORK, December 11.—The copper market remains dull. The production of the Braden company for November is reported at 1,592,000 lb.; Arizona Copper Co., 2,800,000 lb.; Cananea Consolidated, 3,150,000 lb., and Mason Valley, 1,174,000 lb. Report from Lake Superior region states that fighting took place at Houghton yesterday between the striking miners and strike-breakers in which citizens of the city helped the authorities to arrest the strikers and trouble-makers. The lead market is weak and spelter quiet. The stocks are generally quiet, with but few changes and little trading being done.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending	Nov. 25.....

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

	1912.	1913.		1912.	1913.
Jan.	42.53	50.45	July	44.25	40.70
Feb.	42.96	49.07	Aug.	45.80	41.75
Mch.	42.58	46.95	Sept.	48.64	42.45
Apr.	43.92	49.00	Oct.	50.01	40.61

June	45.76	45.10	Dec.	49.80

Tin statistics for November show an increase of 2630 tons in the visible supply, the largest since May of this year, when the increase was 3588 tons. The total visible now stands at 14,470 tons, and the price at the end of November was \$180, compared with 12,348 tons and \$226 last year, and 16,630 tons and \$204 two years ago. The price has since declined to about \$175, or 38c. per pound. According to L. Vogelstein & Co., writing on December 4, the position of tin seems to be quite good and sound, the only unfavorable feature being the larger Straits' shipments. Information to hand is not that the Straits' production is increasing, but that the monthly shipments are swollen by the quantities of ore now being sent to the Straits from Siam, Australia, China, and Africa, to be smelted, instead of going direct to Europe. This material used to be absorbed without appearing in statistics, but now it does so under the head of Straits' shipments. Large Straits' shipments can thus easily create a wrong and bad impression. Considering the position, it is probable that there will again be a gradual decrease in the visible supply and a return to higher prices.

Share trading on the New York Stock Exchange during November totaled 3,725,886 shares, the lowest of any month since May 1897. Monday, November 24, was the duller day on Wall Street since July 3, 1888, there being only 57,605 shares sold. Bond trading for the month was \$33,691,000, the smallest since November 1907. On November 1 there was a shortage of 1842 freight cars on United States railroads, but on November 15 there was a surplus of 22,652 cars. Commercial failures in the country during the last week of the month numbered 356 as reported by R. G. Dun & Co. of New York, against 299 during the second week of the month, and 220 a year ago. The November liabilities total \$16,274,809. Gold exports from New York for 11 months amount to \$68,996,146, and silver \$45,008,638, against \$33,277,176 and \$52,815,563 respectively in 1912. Imports of these metals total \$24,127,486 and \$9,982,220 in 1912, and \$27,596,325 and \$9,136,456 in 1912.

Gold movements in Great Britain from January to October, inclusive, were as follows:

	Imports.	Exports.
Unrefined gold.....	£39,574,489	£ 965,824
Bar gold, refined.....	95,658	20,918,215
Sovereigns.....	10,135,966	17,752,157
Foreign gold coin.....	40,247	602,496
Total.....	£19,846,369	£40,238,692

The totals in 1912 were £41,884,763 and £37,222,996, respectively.

Portable Burners

One of the many uses of portable burners is presented in the halftone, which shows the method of heating an end sill of a steel car with a Hauck portable fuel burner, previous to strengthening it. This little apparatus has come into a wide use in iron and steel repair work, and has greatly expedited work which formerly could only be accomplished by sending the broken parts to a well equipped repair shop, often at a distance of many miles. Among the many uses of the portable burner, it has been found to be a most valuable tool for the welding or straightening of locomotive frames and structural steel of

HEATING THE END SILL OF A STEEL CAR.

all kinds, shrinking of pinions on geared locomotives and hoisting engines, shrinking bands on cracked cylinders, straightening shafts and frames, rebabbiting engines, pre-heating for oxy-acetylene welding, brazing, and numerous other heating purposes. One of the interesting features of the Hauck burners is the clean smokeless flame that can be produced instantly without heating the burner. It is also to be remarked that this burner uses crude oil with better results than gasoline, which insures perfect safety. The ease with which it can be moved from place to place has created a wide field for its use, and it has been found a valuable adjunct in mine and smelter repair work. The apparatus consists of a steel tank of from 8 to 16 gal. capacity, 12 ft. of special oil-resisting rubber hose, 12 ft. of air hose, and the patented Hauck burner, which is made entirely of iron and steel. These burners are being distributed by the Pacific Coast branch of the Hauck Manufacturing Co., with headquarters at 111 Main street, San Francisco.

Commercial Paragraphs

H. W. JOHNS-MANVILLE Co. has opened an office and warehouse at Galveston, Texas.

The A. S. CAMERON STEAM PUMP WORKS reports that a recent addition to the staff of the centrifugal pump department is C. V. Kerr, the organizer of the Kerr Turbine Co., and later with McEwen Bros. of Wellsville, New York. Mr. Kerr delivered an interesting address with stereopticon views on 'A New Centrifugal Pump with Helical Impeller' at the monthly meeting, on November 11, of the American Society of Mechanical Engineers, at their rooms, in New York City.

ASBESTOS PROTECTED METAL Co., of Beaver Falls, Pennsylvania, reports that the Pennsylvania railroad has standardized asbestos protected metal for the enclosing of all buildings using sheet metal roofing or siding except those of a temporary character. Recent orders include a freight station at Harrisburg, freight sheds at Uniontown, dock buildings at Baltimore, Maryland, and pier 29, North river, New

York. Asbestos protected metal is manufactured for the Pennsylvania railroad in special colors to match their standard color scheme, which is a buff ground with dark brown trim and relief. The Asbestos Protected Metal Co. is the only producer of colored asbestos felts in the United States at the present time.

The HARDINGE CONICAL MILL Co. reports that the Bunker Hill & Sullivan Mining & Concentrating Co., of Kellogg, Idaho, has ordered two more 6-ft. Hardinge pebble-mills, bringing its total installation to six units of this size. Other orders include two more sectionalized mills for the interior of South America, also two of the largest size 8 ft. by 30-in. mills for the Silverton Mines, Ltd., of Silverton, British Columbia, which company is installing the flotation system.

The DODGE MANUFACTURING Co. has received an order through Mine & Smelter Supply Co. from the National Copper Mining Co., National Station, Idaho, for the following equipment: 360-hp. Dodge American rope drive from motor to jack-shaft, 225-hp. Dodge American rope drive from jack-shaft to Harding conical main line, 180-hp. Dodge American rope drive from shaft to second main line. On the first drive, 260 ft. of Dodge 'Firmus' manila transmission rope will be used in 24 grooves on 72 and 36-in. sheaves. On the second drive, 700 ft. of Dodge 'Firmus' manila transmission rope will be required in 8 grooves for 60 and 81-in. sheaves. On the last main drive, 850 ft. of Dodge 'Firmus' rope is specified for 6 grooves on 60 and 81-in. sheaves.

LOWERING the water-level in the old Consolidated Virginia property on the Comstock from the 2500 to the 2700-foot level has been commenced by the United Comstock Pumping Association, of which Mr. W. C. Ralston is now president. This, it is hoped, will result in proving that there is such a thing as a mine 'coming back.'

MAKING proper outfitting for Alaskan trails a subject of government supervision, as recommended by Mr. George C. Hazelet in his report to the Cordova Chamber of Commerce, would undoubtedly result in minimizing the perils and hardships experienced by many on the Alaska trails. Whether the annual fatalities recorded are due to the ignorance of the 'cheechaco' or the overconfidence of the 'sourdough', such a regulation, acting as a safeguard on both, would be most effective. As pointed out in the article on 'The Glacier Trail to Shushana,' the method has been proved a success by our Canadian neighbors.

SMELTING complex sulphide ores so as to save all the metals has not heretofore been possible. At best, only a part of the zinc or of the silver and copper could be recovered where the three metals occurred together. On another page Mr. E. W. Hale, chief chemist for the Continuous Zinc Furnace Company, presents results of work done at Hartford, Connecticut, which, while accomplished on a small scale, is significant of possible results of wide interest in the West. The company with which Mr. Hale is connected is now building a three-ton furnace and is preparing to demonstrate that equally good results can be accomplished on a larger scale.

THE Order of Carabao, with its good ships *Fellowship*, *Friendship*, and *Piffle*, which were recently subjected to a broadside from the President, has voiced widespread sentiment among those familiar with Philippine affairs, as to the present policy toward the Islands. While time alone can prove the wisdom of the extremely liberal policy now in vogue, a large percentage of those who have, by years of association, come to know the native, are by no means optimistic as to the result of our present course. If the Filipino is capable of self-government, he should have it; if he is not, and such seems to be the verdict of that part of the army and navy which has been struggling with the Philippine problem in the field, it will have been a decided mistake to allow the solid foundations of good government, which have been established there, to become weakened.

AT the request of Mr. C. E. van Barneveld, chief of the department of mines and metallurgy of the Panama-Pacific exposition, Mr. Thomas T. Read will act as Eastern representative of the department. Intending exhibitors and others interested are invited to consult with Mr. Read regarding plans.

THE Sherman anti-trust law has found a new application in its relation to the coal-miners' strike in Colorado. A federal grand jury has recently returned indictments against the officials and members of the striking miners' organization for violating this law by organizing a conspiracy in restraint of trade. The attempt of the Secretary of Labor, Mr. W. B. Wilson, to bring about a renewal of settlement negotiations, is reported to have met with but little favor on the part of the operators, as was to be expected since his recent utterances have discouraged belief that an unbiased arbitration could be had at his hands.

GIFT of the sum of \$1000 per year for ten years to the University of California by Mr. F. W. Bradley of the class of 1886, is for the purpose of aiding students in the College of Mining whose records and ability "seem to promise that they will be of material service in development of the mining resources of the state." Aid is to be given through loans, and repayments and interest, which is to be charged after graduation, are to be added to the original fund. If this gift proves the means of bringing into the industry even a few such men as its donor, it will have proved well worth while, and Mr. S. B. Christy, dean of the College, is to be congratulated upon this evidence of support and esteem among leaders of mining.

UNITED STATES Geological Survey reports on the mineral production for the calendar year of 1912 shows the output for the period to have been the largest in the history of the industry. The total was valued at \$2,243,630,326, which is an increase of \$316,098,198 over that of the preceding year. With few exceptions the year was a record one in all branches. The increase in the production of copper is the most notable, the total being 1,243,268,720 pounds valued at \$205,139,338, as compared with \$1,097,232,744 pounds in 1911, valued at \$137,154,092. Comparing the statistics for the past 25 years shows that, while there have been periods of comparative depression, the general tendency has been upward, and in spite of occasional predictions to the contrary, the mineral industry is far from decadent. It is reasonable to suppose that the limit of production and exhaustion of resources is a matter still of many years to come.

COAL-MINING fatalities in the United States during the first nine months of the present year, according to statistics collected by the Bureau of Mines, numbered 1843. These figures, made public at a time when the Bureau of Mines is making an effort to expand its scope of operations and render a greater service in the cause of mine safety, are particularly significant and add weight to the President's recently expressed opinion that "the Bureau of Mines ought to be equipped and empowered

to render even more effectual service than it renders now, in improving the conditions of mine labor and making the mines more economically productive as well as more safe. This is an all-important part of the work of conservation; and the conservation of human life and energy lies ever nearer to our interest than the preservation of our material resources."

METAL production of Mexico for the month of July as indicated by the export statistics compiled by the Mexican government, show a decrease of ₧2,837,246 as compared with the same month of the preceding year. Of this amount ₧96,000 was exported as coined gold. The total gold exported shows an increase of ₧354,787; while the silver exports showed a decrease of ₧708,245. The value of the silver bullion exported during July was ₧5,064,111. The copper exports for July were valued at only ₧2,184,308, which is a decrease of ₧3,463,779 as compared with the same month of 1912. Among the other mineral exports antimony declined ₧250,555, lead ₧49,495, and zinc ₧31,190; while asphalt showed an increase of ₧84,721 and petroleum an increase of \$1,237,949. The total mineral exports during July showed a decrease of ₧2,837,246 as compared with the month of July 1911. These figures do not include exports made through ports in the hands of the rebels.

SHAREHOLDERS' interest in a strike is one phase of these industrial turmoils not generally considered as important by those who see only one side of the question at issue; namely, the desirability of shorter hours and higher wages. However, when it is realized that for the millions that have been taken from mines and paid in dividends there have been other millions put into mining investments and which have resulted in nothing more tangible than beautifully engraved stock certificates, it seems equitable that those who are taking the chances and making possible the comparatively small number of successful mining enterprises should be conceded to have some interest in the matter at issue. In the present strike in the Lake Superior copper region it has been estimated that the loss to shareholders will amount to almost \$5,000,000 in this year's dividends alone. In addition there is also the loss due to the irregularity of operations as at present conducted, with its accompanying increase in production cost. If the shareholders should go on a strike for higher dividends and so tie up the mines, would their demands often be met by the miners?

LOUD outcry is frequently heard over the absorption of profits in mining, railway, and industrial enterprises by the financial houses that market their securities. The history of the New York, New Haven & Hartford railroad, recently published, shows that the relation is one that is capable of being abused. At the same time there is no denying the truth of the statement that "persons who decry the close relations existing between the bankers and the great transportation and industrial businesses fail to perceive that, as individuals require the advice of lawyers and physicians, so great enterprises require

financial diagnosticians who can give counsel as to the world's investment markets, as to what form of securities is best adaptable for any given time, as to what financial policy for the corporation is best calculated to command the confidence and the steady support of the investor," made in an open letter to the Pujo committee by J. P. Morgan & Company. Most enterprises that fail, and we include mining companies, do so because they are not soundly financed. Too much or too little capital is put into them, or the ratio of capitalization to earning power is wrongly estimated. We are constantly asked to assist someone having a mining property to find capital, and in the great majority of cases even a brief examination of the papers submitted shows that the business end of the project is unsound. It is regrettable that there is so much popular prejudice against bankers and others to whom the public should turn for advice in financial matters. The whole matter of currency reform could be easily settled if there was a sound public confidence in the disinterestedness of some of the extremely competent men who are offering advice. However, one or two such artistic jobs of wrecking and manipulation by the 'best people' as in the case of the New Haven, account for a mountain of prejudice.

Safety and Health First

In many of his writings, but especially in his 'Data of Ethics', Herbert Spencer has clearly indicated the total change brought about in human relationships when society advances from that stage in which war is a normal state to our present level in which war is a deplorable evil to be avoided so far as possible. With this advance comes a sweeping change in the whole viewpoint of mankind, and such great readjustments in the relationships of men to each other that we are only just coming to realize their full extent and importance. To forward-looking men, one of the most encouraging signs of the times and evidences of marked progress is the first International Safety and Sanitation Congress, held, under the auspices of the American Museum of Safety, in New York on December 10, 11, and 12. The subjects discussed were industrial accidents, accident prevention and the public, industrial hygiene, employer and employee, and the coming generation. Nearly a hundred speakers were heard, representing such large and important organizations as the Pennsylvania railroad, United States Steel Corporation, the General Electric Company, United Gas Improvement Company, Interborough Rapid Transit Company, Travelers Insurance Company, the National Consumers League, Carnegie Steel Company, Illinois Steel Company, New York Central Railroad, United States Department of Labor, Wanamaker's, Ohio State Department of Health, New York Industrial Commission, Illuminating Engineers Society, Brotherhood of Railway Trainmen, Industrial Relations Commission, Women's Trade Union League, National Association of Corporation Schools, Public Service Corporation of New Jersey, Pennsylvania Commission of Labor and Industry, New York City Bureau of Fire Prevention, and others too numerous even for mention. That

such a variety of organizations does not argue a lack of unity of purpose was well brought out by Miss Leonora O'Reilly, who, speaking for the Women's Trade Union League, and with a force and fluency characteristic of her race, classified mankind into the working and the loafing classes, and pointed out that work is a natural expression of human energy and that the needs and aspirations of workers of all grades are fundamentally the same. On such a happy basis of unity the discussions proceeded, bringing out with clearness the modern viewpoint that in well conducted industry the energies of the worker must be released from combatting unfavorable conditions and employed only on useful and productive forms of work. The idea that the necessary risks of industry must be borne by the industry itself, and not shifted upon the worker or society in general, is now so widely accepted and has been so generally incorporated into recent legislation, that further discussion is unnecessary, except in so far as it relates to devising and improving methods of decreasing the risk and of carrying its burden. Thus Dr. W. Irving Clark, of the Norton Company, told of the good results attained through the preliminary and periodic medical examination of all workmen, whereby fewer accidents and less loss of time per month were benefits secondary to the fact that workmen suffering from hernia and heart disease were prevented from injuring themselves. Similar examinations are now the rule with many of the mining and smelting companies, the American Smelting & Refining Company, for example. An interesting feature of the work of the Illinois Steel Company is the employment of 'plant preachers,' who talk interestingly on the subject of accident prevention to their fellow-workmen during the lunch hour. The result of this and numerous other devices has been the saving from injury and death of many good men since 1906, corresponding to a decrease of 46 per cent in the number of accidents. The important effect of light on accidents is shown by the fact that in some lines of industry the number of accidents at night is double that in the daylight hours. The extra cost of illumination is often repaid by the more effective work thus rendered possible, making the saving in accidents clear gain. Ventilation is almost equally important, though a better understood subject, yet here also marked advance is still possible. The beneficial effect of pleasant surroundings has been so clearly demonstrated in the case of some companies which have surrounded their plants with recreation grounds and gardens, that it has been found worth while to lengthen the lunch period to 1½ hours so as to afford time for reaping the full benefits. This is not charity, it is good business, and yet it is also justifiable and commendable on highest grounds of humanitarianism. It is impossible to treat the subject more at length here, but we hope to give, later, some accounts of what has and can be done by mining companies. Plans are maturing for the consideration of work of this sort by the American Institute of Mining Engineers, and we are sure that much of benefit to employer and employee alike will result from its careful consideration.

The Rand Banket—Part VI Continued

By C. B. HORWOOD

The Distribution of the Gold.

(e) *Black-Edged Pink, and Milk-White Pebbles.*—About six and a half years ago, at the Star section

upper one varying in thickness from 8 or 10 in. to 18 or 20 in.; a middle one varying from about 3 to 5 in.; and a lower one varying from a single line of

FIG. 28.

of the Consolidated Langlaagte mines²⁹⁶ the writer first particularly noticed white, gray, or bluish-gray black-edged lustrous quartz pebbles in the banket.

FIG. 29.

pebbles up to 2 to 6 in. thick. These layers of banket are separated from each other by a few inches of intervening quartzite.²⁹⁷ The narrow lowest seam, as it carries nearly all the gold, is the profitable member of the series, and is known as the South Reef Leader. When typically developed as a single-pebbled layer the pebbles may be adjacent, or nearly so, but they are often one or two, up to as much as 5 in. apart; occasionally, they may be even a foot or two, or more, apart. Indeed, in the face of development drives²⁹⁸ the banket is sometimes only represented by two or three pebbles; and sometimes no pebbles are to be seen, in which case one may be only able to judge from the appearance of the quartzite whether the face of the drive contains the line of the lode or not. This is often possible, by careful observation, because, as a rule, the South Reef Leader occurs in a dense black crystalline quartzite, and there is usually a sharp line of demarcation between this black quartzite and

In these mines the South Reef series consists of either two or three leaders, generally three. There is an

²⁹⁶These mines are at Langlaagte, a township about 4 miles west of Johannesburg.

²⁹⁷This series, as it occurs in these mines, has already been described in the first part of this paper.

²⁹⁸The dip in these mines is about 35°. In advancing the

the whitish, comparatively soft foot-wall quartzite on which it rests. When present, the Leader generally rests immediately on, or, at the most,

FIG. 30.

lies not more than a few inches above this whitish quartzite, which forms the foot-wall. When absent or represented merely by an occasional pebble, it is quite an easy matter for the line of the banket to be missed either in development work or in actual stoping. Thus the careful study of its characteristics, especially in mines where it is poorly developed, is of the utmost importance, since it is the main gold-carrier of this series;²⁹⁹ and any peculiarity or distinctive feature that helps to distinguish it from other 'reefs' becomes valuable. In these particular mines its pebbles have well rounded contours: some are spherical in section; but a large number, probably the majority, are oval or oblong, and have their longer axes parallel to

FIG. 32.

the dip of the strata; many are like the flat oval pebbles so frequently found on sea-beaches at the drives, which are usually about 6 ft. wide, it is customary to do so in such a way that the bottom of the banket it is intended to exploit is at about the height of a man's shoulder on the foot-wall side of the drives; so that when stoping begins the broken ore can be gravitated into the trucks in the drives below the stopes. [The word 'drive' as used by the author is the equivalent of the technical term 'drift.'—EDITHA.]

²⁹⁹Even when no pebbles are present, the line of the lode generally carries gold.

present day and give one the impression that they have not traveled far.³⁰⁰ They vary greatly in length, from less than half an inch up to about 2 inches in greatest diameter. They are mostly translucent crystalline lustrous quartz pebbles, light to dark-gray or bluish-gray in color; in some of these the outer circumferential portion is black, forming a black edging; a few consist of black crystalline lustrous quartz; there are occasional amorphous milk-white quartz pebbles; also occasional rather resinous-looking pebbles which by candle-light underground exhibit a slight pink tinge.³⁰¹ In thin section under the microscope the latter were found by the writer to consist of quartzite. Long practical experience on these mines has proved that these pink resinous-looking pebbles in particular,³⁰² and also the black-edged quartz pebbles are an indication of good ore. This being so, it seemed to the writer that their color must, in some way, be connected with the agencies to which the bankets owe their gold.

FIG. 31.

Origin of Black-Edged Pebbles

With regard to the origin of the black-edged pebbles, the writer soon observed that pebbles occurred in all stages from white to black. The gradations pass from pebbles with just a mere thin outer layer of black to those in which this layer is thicker; and, again, from these to pebbles that are almost entirely black except for a small white central portion; lastly come pebbles that are entirely black. Therefore, one of two processes must have taken place; either these pebbles were originally all black, and were finally converted into white pebbles through some process of decoloration that started from the centres; or they were originally white and the pro-

³⁰⁰This is rather exceptional; in most of the mines on the Rand the quartz pebbles are not flattish, but are very well rounded.

³⁰¹It is seldom that these pebbles exhibit a pink tinge by daylight. When brought to the surface they appear a dirty yellow color.

³⁰²A. D. Bacon, formerly general manager of the Langlaagte Estate mines, informed the writer that his experience on those mines proved conclusively that these resinous-looking pink pebbles were an infallible sign of good ore.

cess of converting them into black ones has proceeded from the circumference toward the centre. It seems impossible to imagine how the first could have operated. It is sufficiently difficult to account for the physical conditions under which the second could have taken place. It has been shown that pyrite has replaced quartz in the banket; and that

bles by being diffused through it either by replacing portions metasomatically in an extremely finely divided state, or by actually penetrating it without replacement; or by insinuating itself between the in-

FIG. 33.

carbon has also, to some extent, done the same. The latter is capable of producing a black coloration. Probably also the former; and possibly gold,³⁰³ manganese, chromium, and other elements, if in a sufficiently finely divided state, may be capable, under certain conditions, of coloring the quartz of the peb-

³⁰³Here it is interesting in connection with the slight pink coloration of some few of the pebbles to recall that a pink sublimate can be obtained on aluminium foil by volatilizing gold with a strong blow-pipe flame. (See Ross' 'Pyrology'; and also 'The Blowpipe in Chemistry, Mineralogy, and Geology,' by W. A. Ross (1912), published by Crosby, Lockwood & Son. In this process a carbon slip is employed and gold is heated with lead on aluminium foil, as described in these two books.

FIG. 34.

dividual irregular granules of which it is composed. The higher the temperature of the solution (either liquid or gaseous) containing any of these elements, and the greater the pressure, the more would be the physical and chemical activity and therefore the

FIG. 35.

greater the likelihood of, one or more, such changes taking place.

FIG. 36.

Later the writer studied the occurrence of similar pebbles at the Rietfontein mines, situated some 12 miles farther east. Here also he noticed that pebbles could be found in different stages from white lustrous quartz with a well defined black edge up to an entirely black lustrous quartz pebble. Quartzite pebbles with a pink tinge also occur, and experience showed that both were indications of good ore. Amorphous milky-white quartz pebbles are found, and they too are a sign of good ore. From the mode of occurrence of the latter there can be little doubt that they were originally translucent white crystalline quartz pebbles that have undergone subsequent alteration.³⁰⁴ At the Rietfontein mines the writer sometimes noticed, near a dike, a change from the ordinary white lustrous crystalline pebbles to these amorphous milky-white quartz pebbles. Further, he has constantly noticed underground that where rock is shattered by blasting the ordinary lustrous light

the gold-bearing member of the series in which it occurs.

Pink Tinged Pebbles

Attention was first directed to these black-edges by the writer in 1910. At the same time he also called attention to the presence of pebbles with a pink tinge and to their close association with good ore.³⁰⁶ Fig. 28 to 32 show the appearance of these black-edged pebbles. In Fig. 28 and 29 the outlines of the black-edged pebbles do not appear well defined, although they are clear in the original specimens. This is owing to the high-lights in the photographs. Fig. 29 is of a specimen that illustrates well the association of these pebbles with high-grade ore, as the other side of the specimen contains much gold, which is present in such a way as to remind one of the way butter is often smeared over bread. Fig. 30 is of one of these pebbles, about 3 in. long,

FIG. 37.

FIG. 38.

or dark-gray or bluish-gray pebbles are changed to amorphous milky-white ones.

Still later the writer studied the occurrence of pebbles similar to those described in the lodes of the various Randfontein mines, which are 20 miles west of the Consolidated Langlaagte. There again he found that practical experience proved that the pink pebbles, black-edged quartz pebbles, and black lustrous crystalline quartz pebbles are invariable signs of good gold contents. As at the Consolidated Langlaagte the black-edged quartz pebbles are a distinctive feature of the lode known as the South Reef Leader, so at the Randfontein mines black-edged quartz pebbles are one of the chief characteristics, particularly when the ore is rich, of that lode known as the Randfontein Leader,³⁰⁵ which is

³⁰⁴For example, at the Star mine in the Main Reef Leader, on No. 3 level, where the ground was disturbed and faulted, the writer found in one place right in the faulted ground, and where waters were still circulating, that some of the pebbles were milk-white and amorphous, and that others occurred in various intermediate stages between this and entirely translucent and crystalline forms. The occurrence was such as to suggest that the amorphous milk-white pebbles had originally been ordinary translucent crystalline white pebbles, and that the alteration was due to dynamic or chemical causes, or perhaps to a combination of both.

³⁰⁵The Randfontein Leader on this part of the Rand is the representative of, and can be correlated with, the South Reef Leader.

from a thin 'leader,' underlain immediately by a dike, in the western section of the New Rietfontein mines. Fig. 31 shows a typical black-edged pebble from a drive; the pay leader has here so diminished in size that it is represented merely by this one pebble. Fig. 32 is a splendid example of a black-edged quartz pebble. A slice has been cut from this pebble, leaving a polished surface that helps to bring out the black edge of the pebble in sharp relief. Around the left side of this pebble there is a heavy edging of pyrite, which in the specimen, with the aid of a good magnifying glass can be seen embaying and fretting, and some of it enclosed in, the black circumferential portion of the pebble. This can even be seen in the figure with a strong magnifying glass.

Sections of Pebbles

The writer had many thin sections cut of these black-edged pebbles; and some of these are shown in Fig. 33, 34, and 35, from photographs in which they are all considerably enlarged from the original slides. Fig. 33 is of a thick section (varying from $\frac{1}{32}$ to $\frac{1}{16}$ in. thick), mounted on a slide without a cover-slip. It shows the black edge very distinctly. Fig. 34 and 35 are of two sections mounted in the ordinary way for examination under the microscope; they show the black edging of the pebbles very well,

³⁰⁶'The Mode of Occurrence and Genesis of the Carbon in the Rand Banket,' by C. B. Horwood, *loc. cit.*, pp. 67 and 74.

and also the surrounding matrix of the banket, and examination under the microscope indicated that the coloring matter had in the first place worked inward from the circumference by insinuating itself along the edges of the irregular interlocking granules of which the quartz mosaics of the pebbles consist and had then, in places, diffused through the quartz itself. The writer was unable, however, even with a high-power oil-immersion lens to determine the dark dusty coloring matter. Fig. 36 shows, in enlarged form, two opposite ends, of one of these pebbles; from the central portion of which five thin complete slices (right through it) were cut and mounted for microscopic examination. The black margin is distinct in this figure and the way it spreads inward, like the ragged-edge of a black cloud, is clear. In the one on the left, on the side nearer the edge of the plate, the way the pigment works round and between the granules can be seen, and also how it then diffuses inward toward the central portions of the individual granules. Fig. 37 and 38 are of photographs taken by transmitted light of two of the thin sections cut from the black-edged pebble shown in Fig. 36 and mounted on glass for examination with the microscope. Although the black edge and its extent is plain in the original sections (which are much enlarged in the figures), it is not clear in the illustrations, owing to the strong light behind them when they were photographed. These two figures show the manner in which the dusky coloring matter has insinuated itself between the quartz granules of the pebbles and how it then diffuses into these granules. The photographs also illustrate beautifully the mosaic structure so typical of the quartz pebbles of the banket. The structure is due to the numerous small irregular interlocking granules of which the quartz is composed. From examination of numerous sections under the microscope, and from these figures, it is manifest that the agencies to which the black coloration of these pebbles is due possessed extraordinary powers of penetration and diffusion.

Diffusion of Metals

It may, therefore, be well at this stage to touch briefly on some aspects of diffusion, especially at high temperatures. The great diffusive power of certain medicinal substances and of scents, in spite often of extreme attenuation, is well known; and also the ability possessed by even minute traces of certain metals to produce coloring effect. This quality of diffusion indicates molecular mobility; a good example of this being furnished by the great rapidity with which mercury will penetrate a bar of tin.³⁰⁷ Thus if a tin bar of tin (say 2 in. square and $\frac{1}{2}$ in. to 1 in. thick) a notch, say $\frac{1}{8}$ in. deep be cut, and right across it, as shown below, and this be filled

³⁰⁷Homberg, 'Mém de l'Acad. Royale des Sciences,' 1713 (volume published 1739), p. 306.

with mercury, the latter will quickly soak through the tin and the bar can then easily be broken, owing to the fact that the mercury has diffused between the crystalline grains of the tin. This is a case of the diffusion at ordinary temperatures of a mobile metal (which is liquid at ordinary temperatures) through a solid one. Roberts-Austen³⁰⁸ pointed out that where diffusion is concerned small variations of temperature may be of great importance, the diffusibility being greatly increased by a rise of temperature; and that Graham³⁰⁹ was of the opinion that the effect of high temperatures is "to assimilate diffusibilities" of different salts.

Thus it will be readily understood that metals and other substances if existing under high pressure and temperature conditions as pneumatolytic vapors would have their diffusive qualities greatly enhanced. Good examples of coloration produced by pneumatolytic vapors is furnished by some of the tin deposits of the Bushveld area of the Transvaal. At the Rooiberg tin mine, some 40 miles west of Warmbaths, the cassiterite occurs as an actual replacement and also as an impregnation in those sandstones and quartzites now known as the Rooiberg series, of the Waterberg formation. It is found in various forms such as (1) replacements and impregnations of the country-rock, (2) lenticular-shaped deposits along bedding-planes, and (3) in rich pockets of almost pure cassiterite. In all these cases the deposits can be traced to fissures. One of the characteristic features of these pockets is a concentric structure. This consists usually of a light-gray ring of secondary silicious matter, and beyond this another ring produced by the deep red coloration of the adjacent quartzite, which has undergone feldspathization. Between these two rings there are often layers of tourmaline.³¹⁰ At the Zaaiplaats tin mine, about 20 miles northwest of Potgietersrust, the cassiterite, so far, has mainly occurred in small pipes in the Red granite. The author particularly noticed that the color of the granite immediately round the pipes was often of a much deeper red, and that a great deal of tourmalization had taken place. In each case the red coloration and its close association with the presence of cassiterite and tourmaline point to its being one of the effects of that pneumatolytic action to which the presence of these two minerals must be ascribed.

Analyses of Black-Edged Pebbles

As regards the black-edged pebbles, in order to see whether chemical analysis would disclose the coloring matter,³¹¹ several were collected and separated as carefully as possible from the matrix; but,

³⁰⁸'On the Diffusion of Metals,' by Sir W. C. Roberts-Austen, *Phil. Trans., A. Roy. Soc.* (1896), see pp. 383-415. The reader is particularly recommended to carefully read this paper, as well as certain papers on diffusion in the *Proc. Roy. Soc.*, Vol. 67, No. 436 (1900).

³⁰⁹Graham, *Phil. Trans. Roy. Soc.* (1861), pp. 183-224.

³¹⁰For this description of the occurrence of cassiterite at Rooiberg the author is indebted to E. R. Shock, the manager of the mine.

³¹¹In addition, the writer tried blow-pipe tests on small particles of the black-edging. With a borax bead the presence of iron was indicated. With a bead of equal parts of sodium carbonate and potassium nitrate the presence of manganese and chromium was suggested. These reactions were not well marked and were therefore unsatisfactory.

for the most part, it was found impossible entirely to free the surfaces from a small amount of adhering matter consisting of a little iron pyrite, free gold, and carbon. In the process of separating the pebbles from the matrix the former were mostly broken into pieces, which were collected as carefully as possible. In several pieces the black coloring matter could be seen spreading inward in jagged tongues from the circumference of the pebbles; and, in one instance, by the aid of a strong glass it could be seen surrounding some of the individual crystalline granules of which the quartz pebble was composed. In these pebbles the black edges varied in thickness from a thin streak round the circumference up to about one-sixteenth, and in one place up to about one-eighth of an inch thick. At the same time ordinary white or light-gray lustrous quartz pebbles were collected, and separated as carefully as possible from the surrounding matrix. These seemed to have a still greater tendency to break during the process of hammering and chipping the surrounding material of the blanket, and so the pebbles after isolation were only obtained in broken pieces: unlike the black-edged pebbles, there was little closely adhering foreign matter and it was found possible to clean them far better than the former. The small amount of adherent matter still remaining consisted of a little iron pyrite and a little greenish-looking substance that appeared to be a decomposition product from pyrite. The pebbles in both cases were obtained from one of the Randfontein Leader stopes of the North Randfontein mine.³¹² This stope-face was about 200 ft. long, and its average assay-value at the time was about 13½ dwt. over a width of 52 in. These two samples were carefully analyzed,³¹³ with the following results:

	A, %	B, %
SiO ₂	96.10	97.40
Al ₂ O ₃	0.69	trace

Gold expressed in dwt. per ton (of 2000 lb.)	145	8
Total weights of samples in grammes.....	78	77
Specific gravities	2.66	2.65

Column A gives the analysis of the black-edged quartz pebbles; and column B gives that of the ordinary white or light-gray quartz pebbles.

Coloring Material of Pebbles

These analyses show, as one would expect with quartz pebbles, that the silica percentage in each case is very high. The most notable differences in

³¹²These pebbles were from the north face of 9.3 Leader stope.

³¹³The analyses were made for the writer by E. H. Croghan of Johannesburg.

them are that the black-edged pebbles contained 18 times as much gold as the others; 0.8% more iron pyrite, with 0.69% of alumina and 0.1% of phosphoric acid, as against traces in the other case. Each sample contained traces of carbon and of titanium; but no manganese was detected. The evidence thus obtained merely suggests that the coloring matter may be due to traces of carbon or possibly titanium; or to the presence of mineral matter such as gold or pyrite, or possibly both, in a finely divided state.

It has already been pointed out that carbon, and probably pyrite, gold, manganese, chromium, and other metals, under certain conditions and in a sufficiently finely divided state, or in a state of diffusion, are capable of producing a coloration. Sollas ascribes the black color in flints to a carbonaceous pigment, the last residuum of the living protoplasm once present in the chalk.³¹⁴ It is now generally admitted that the coloring matter in the so-called moss agates is an iron compound deposited in the silica in dendritic form.³¹⁵ In the cyanide process for the extraction of gold, the latter is thrown down in a finely divided state as a black powder on the zinc shavings in the extractor-boxes. The typical black color of much of the Black Reef quartzite is probably due to manganese that has been leached out of the overlying dolomite.³¹⁶ As already stated, minute traces of certain metals are sometimes sufficient to produce strong coloring effect; for instance, a very little of a cobalt compound fused with borax is sufficient to produce a blue coloration; the same effect is produced if a small quantity of one of its salts is added to ordinary potash-glass while the latter is in a molten state. Amethysts owe their color to manganese; rubies and sapphires to chromium compounds. Again, the resulting color seems often to depend on the degree of fineness of division: for example, although the precipitated gold in the extractor-boxes is black, finely divided gold may be purple by reflected and green by transmitted light.³¹⁷ Gold thrown down from a solution of gold ehloride by the action of sunlight is of various shades of iridescent brown. The greenish blue color of the London clay has been ascribed to finely divided pyrite. The difference in color exhibited, under varying conditions, by the same substance is well exemplified in the case of water. When pure, and seen in moderate quantity it appears to be colorless; but when viewed through a stratum of considerable thickness it presents a beautiful greenish-blue color. Aitken has shown that the presence of extremely finely divided suspended matter in water will give the liquid a blue color. Thus in tanks where water

³¹⁴J. W. Sollas, *op. cit.*, p. 142.
³¹⁵For the information with regard to amethysts, rubies, sapphires, and moss agates, the writer is indebted to Prof. John W. Judd, who also informed him with regard to the latter that Thomas Davies, an able mineralogist who did much work in the arrangement of the specimens in the British Museum, thought at one time that in spite of the dendritic simulations there were real 'fossil mosses' in some of these agates; and he tried to separate the two forms.

³¹⁷'Gold, Its Geological Occurrence and Geographical Distribution,' by J. Malcolm MacLaren, p. 22.

is being softened by milk of lime, after most of the precipitated chalk has settled and only the finest particles still remain suspended in the water, the water often appears to be of a rich blue color. The water of many Swiss lakes has a wonderful blue color, which is partly due to this optical phenomenon, as well as to the actual color of the water itself. The writer has often noticed, in places, the true greenish-blue color of water in the Swiss glaciers, when the frozen snow, or ice, is broken in such a way that the light is reflected from side to side of small crevices, or of crevasses.³¹⁸ From the above it will be clear that minute traces of a substance are often sufficient to produce strong coloration in a material, and that the physical state of a substance may affect its color; and in any particular substance it is often an extremely difficult matter to determine the coloring matter.

Experiments on Black-Edged Pebbles

In the chemical analyses of the black-edged and of the ordinary quartz pebbles, a trace has been entered in each case against carbon, but in a covering letter from the analyst it was explained that carbon could not be detected by any quantitative method. The evidence was purely a qualitative one based on the physical appearance of the silicic acid precipitate. Several trials were made with fresh portions of the sample, and in every case a gray-colored product was obtained, which still remained on drying at 150° to 160°. On ignition, however, the color disappeared, leaving the product perfectly white. In these tests there was no contact with organic matter of any kind, and the chemicals used were quite pure. Comparative tests were then made under exactly similar conditions with silica prepared free from organic matter, and the silicic acid precipitate obtained after treatment of the fused product with acids, washing, etc., gave a perfectly white product. The gray coloration obtained from the samples of the pebbles suggests the presence of some organic matter. These analyses, while interesting and suggestive, do not conclusively prove anything. Owing to the impracticability of obtaining the pebbles absolutely free from any adherent matter, minute traces of carbon may have been present merely on the surface of the pebbles. The author wished to see if acids or high temperature had any effect on the pigment responsible for the black edging of these pebbles. He therefore had several thin slices cut from one of these pebbles³¹⁹ and treated them with acids; and also exposed them to high temperatures in a muffle-furnace. No effect was produced after digesting them for five days with hydrochloric acid, or by similar treatment with *aqua regia*. He then treated one of them with a mixture of nitric acid and potassium chlorate, which is a solvent for carbon. It was first heated on the hot plate for about 5 hours and then put away and allowed to cool for 5 days. After that, as there was

no appreciable result, it was heated on the hot plate for about 7 hours per day for 3 days, still with no result. It was then put away and left until it had been in the mixture for 34 days, and as it still showed no change, the experiment was discontinued. Another slice was treated in a mixture of sulphuric acid and potassium bichromate, which is also a solvent for carbon, and for 3 days it was heated for 7 hours with the mixture on the hot plate, with the result that the black-edging seemed to be very slowly disappearing. It was then allowed to cool and left until it had been in the acid mixture 23 days. When examined it was found that the coloring matter had for the most part disappeared; but as there were still places where the black-edging remained, it was put back again into the mixture. Six days later it was again examined and still more of the color had disappeared. It was then washed and put into a fresh mixture of sulphuric acid and potassium bichromate from which it was removed after 17 days, when still more of the black coloration had disappeared. He then heated a thin slice of one of these pebbles³²⁰ on a Morganite cupel in a muffle at a temperature of about 900°C.³²¹ for about 4 hours. When removed it was found that the black color had entirely disappeared. On cooling, the pebble assumed a milky-white color similar to that already mentioned, of pebbles often found near a dike, or assumed by pebbles in ground that has been disturbed or shattered by blasting. Another effect of the heating was that the pebble showed a distinct tendency to separate from the surrounding matrix and was, in places, no longer in contact with it. The experiment was repeated with another thin section of one of these pebbles heated for about 2 hours at about 1000°C. At the end of this time it was found that the black edging had entirely disappeared; the pebble had, as in the previous case, lost its vitreous lustre and had assumed a milky-white color.³²²

Results of High-Temperature Tests

The high-temperature experiments suggested the possibility of the presence of some form of hydrocarbon that had been driven off on heating. On the other hand, the prolonged tests with carbon solvents did not altogether confirm this indication, since the nitric acid and potassium chlorate mixture had no effect on the black coloration. It, therefore, seemed to the writer that a more decisive method of investigation would be by spectroscopic analysis. If the spectra form (1) a powdered specimen of the black-

³²⁰The slice used was from a gray lustrous quartz pebble of ellipsoidal shape; and the major and minor axes were $1\frac{1}{32}$ and $\frac{5}{16}$ in. long. The black-edging was about $\frac{1}{32}$ in. wide and very distinct and well marked. The thickness of the slice varied from $\frac{1}{32}$ to $\frac{1}{16}$ of an inch.

³²¹As measured with an optical pyrometer.

³²²As spectroscopic analyses, which were being made, had by this time disclosed the presence of manganese it occurred to the writer to see whether dendritic markings underwent change at high temperatures. He therefore exposed a specimen of rock with dendritic markings on a scorifying dish to a temperature of about 900°C. in a muffle-furnace. He also put some manganese dioxide in another scorifying dish and had it in the muffle at the same time. After $2\frac{1}{4}$ hours the dendritic markings were unchanged, but the black manganese dioxide had been converted into a dark brown earthy substance, which was presumably the tetroxide (Mn_2O_4).

³¹⁸For these details regarding the color of water, see 'Inorganic Chemistry,' by G. S. Newth (1912), p. 213.

³¹⁹These slices were cut from a gray lustrous black-edged quartz pebble of ellipsoidal shape and about $\frac{7}{16}$ inch in greatest diameter. The average thickness of each slice was about $\frac{1}{16}$ in.; and the black-edging averaged about $\frac{1}{16}$ inch in width and was very well marked and distinct.

edging. (2) from the interior white or light-gray portion of one of these pebbles, and also (3) from a powdered specimen of an ordinary white quartz pebble were obtained and placed below the other in such a way that the lines common to both were continuous with one another, then any lines peculiar to, or much more strongly developed in, the spectra of the black-edged portion should at once be apparent.

first taken of a small thin splinter from the black edge of one of these pebbles. This spectrum showed no lines that were not also present in the spectrum given by the poles alone. In this experiment the spark seemed to pass round the small splinter of the pebble instead of through it, which doubtless accounts for the negative result. Some of the black edge of one of these pebbles was then powdered and

Careful spectroscopic analyses³²³ were made at the Solar Physics Laboratory at South Kensington,³²⁴ with the following results: A spark spectrum was

an arc spectrum on silver poles was taken in the usual way. This gave no evidence of carbon being present; but it revealed the presence of manganese and chromium, which had not been detected in the chemical analysis. In the case of chromium the evidence was decisive, as there was no trace of this metal in the spectrum given by the silver poles alone. In the case of manganese, the silver poles³²⁵ were found to contain traces as an impurity. A check experiment was therefore made, copper poles free from manganese being used. By comparing the spectrum given by the copper poles alone with that given by the powder on these poles, the presence of manganese in the latter is at once apparent. Four series of spectra are shown in Fig. 39. The two top series are evidence of the presence of chromium, and in doing them silver poles, free from chromium, were used. The two lower series are the evidence for the presence of manganese; and copper poles free from manganese, were employed.

Spectrum Analyses

In series No. 1 the top spectrum marked *a* is that of the silver poles alone; the next, or *b*, is of the powdered black edging on the silver poles; and the

³²³The black-edged pebbles used for these arc experiments (both with silver and with the copper poles) was a fine specimen from the Robinson-Randfontein mine (from 3.7 Leader stope). This pebble was oval with well rounded contours; the major and minor axes were about 1¼ and 1⅛ in. long respectively. It was associated with plenty of gold, which was visible in the immediately surrounding fine-grained dark-gray matrix. Gold and pyrite could be seen, in places, in immediate contact with the black edge and occasionally actually within it. The white or light-gray portion, from the interior of a black-edged pebble, which was used in these analyses was from the interior portion of this same pebble; although of a light-gray color, it was rather darker than that from an ordinary white quartz pebble used in order to compare their spectra. The specimen of an ordinary white lustrous quartz pebble was from a portion of the white quartz pebble with a jagged edge, which is seen on the extreme left of the specimen in Fig. 28. The specimens were, of course, in each case finely powdered before being used.

³²⁴These analyses were done by C. P. Butler, who took a keen interest in this research work and to whom (as well as to Mr. Boxandall, for measuring the wave lengths) the author is greatly indebted. It was through the kindness of J. W. S. Lockyer and with the permission of the Director, Sir J. Norman Lockyer, that the writer was able to have this work done; and he takes this opportunity of recording his thanks to them.

³²⁵These poles were of special purity (consisting of 99.84% of silver); and were obtained from the Royal Mint.

lowest of the three, or *c*, is of the light-gray interior portion of the black-edged pebble. In series No. 2, *a* is a spectrum of the silver poles alone; *b* is of a powdered portion of an ordinary white lustrous quartz pebble on the silver poles; *c* is the spectrum of the powdered black edging superimposed on the powder used for *b*, on the same poles. The most striking result of these analyses is the presence of chromium lines in *b* in No. 1 and in *c* in No. 2, that is, in the two spectra of the black edging; also the presence of manganese lines in the spectrum of the black edging in No. 1, while they have not come out in that of the silver poles, or of that of the interior portion of the black-edged pebble. Turning now to No. 3 and 4; in the former *a* is a spectrum of copper poles alone; *b* is one of black edging on the copper poles; *c* is of the interior light colored portion of the black-edged pebble on the same poles. In the latter *a* is a spectrum of the copper poles alone; *b* is that of ordinary white lustrous quartz pebble on the copper poles; and *c* is of the interior portion of a black-edged pebble superimposed on the powder of the ordinary white quartz pebble, on the same poles. The outstanding feature of these analyses is the presence of manganese lines in spectrum *b* of the black edging in No. 3, and their absence in the other cases. The silicon line, of course, stands out in all these, except in those of the poles alone; and, also in *c* of series No. 3 in which the spectrum has not extended far enough to include this line. The black edging shows no trace of the lines of gold or silver. In the case of iron, the lines occurred just as strongly in the spectrum of the silver poles alone as in that of the black edging on the same poles, thus giving no evidence of its presence in the black edging. The spectra on silver poles suggest the presence of aluminium and strontium in the black-edging; and that it contains these in greater amount than the interior portion of the black-edged pebbles. In comparing the spectra of the black-edging with that of an ordinary white lustrous quartz pebble the only striking difference is the conspicuousness of the chromium lines in the former, there being only the slightest trace of them in the latter. Using copper poles, the spectra of the black edging show the lines of manganese, iron, aluminium, and chromium, none of which are present in the spectrum of the poles alone. The same lines are present but are very weak in spectra of the interior light-colored portion of the black-edged pebbles, showing that these elements predominate in the black-edging. Although the spectrum of the black-edging when silver poles were used seemed to indicate the presence of strontium, this was not supported by the spectrum on copper poles, which showed no trace of strontium lines.

Summary of Tests

The outstanding feature of these differential spectroscopic analyses, confirmed by the employment of both silver poles and also copper poles, is the presence in the black edging, of chromium, manganese, and aluminium;³²⁶ and of these, the coloration would doubtless be due to the first two.

³²⁶The presence of alumina, coupled with the great amount of silicification to which the bankets have been subjected, suggest that the manganese and chromium may have

The study of the mode of occurrence of these pebbles clearly demonstrates that they are associated with the presence of gold. The microscopic examination of thin sections reveals that the coloring matter has introduced itself into the pebbles from without by insinuating itself between the irregular-shaped granules of the quartz mosaics of which the pebbles consist; and then commenced to penetrate, and diffuse within, these granules. Such great power of penetration and diffusion points to the agency of a fluid so mobile that it probably existed in the gaseous state and under pressure. If the pigment is a condensation product from pneumatolytic vapors, then under ordinary atmospheric pressure, it might be capable of being re-vaporized if exposed to a sufficiently high temperature; and the muffle experiments have shown that the color actually is destroyed when exposed to a high temperature. The spectroscopic investigations indicate that the pigment is due to manganese and chromium compounds. Weed³²⁷ has recently drawn attention to the phenomenon, often previously noted, that "in many gold deposits manganese oxides and gold are intimately associated and without doubt have been precipitated together," and that this association is by no means uncommon. The study of these black-edged pebbles leads, therefore, to the following conclusions: (1) The coloring matter owes its existence in the pebbles to the same agencies to which the gold in the banket is due; (2) the coloration is the result of the presence of manganese and chromium, or their compounds, and also possibly of iron; (3) these latter have been introduced under pneumatolytic conditions.

(f) *Black Crystalline Quartzites*.—The presence of black, crystalline, lustrous, and dense-looking quartzite is generally indicative of the ore being of good grade. For example, it has already been pointed out that the quartzite matrix of the South Reef Leader is much darker than the foot-wall quartzite on which it rests. The latter is of a schistose character and has undergone sericitization, while the former has undergone intense silicification; the foot-wall is light-gray in color, while the quartzitic matrix of the Leader and the quartzite in which it is immediately imbedded varies in color from dark-gray to black.

Influence of Igneous Intrusion

Sometimes the banket and the quartzite have been blackened owing to the influence of a neighboring igneous intrusion. The writer has, in a previous paper,³²⁸ described a good example of this at the North Randfontein mine, where the West Reef³²⁹

formed complicated aluminium silicates. The close association of chloritoid with the gold, and the fact that what may well be considered a variety of it (that is, ottrelite in which manganese takes the place of magnesium) is a basic silicate of aluminium and ferrous iron, lends support to this idea. Apparently a trace of iron is also present and may have played some part in the coloration.

³²⁸'The Mode of Occurrence and Genesis of the Carbon in the Rand Bankets,' *loc. cit.*, p. 72.

³²⁹Which is correlated with the Main Reef series of the Central Rand.

is immediately overlain by an intrusive diabase dike, which forms the hanging wall of the lode. This dike has had a marked effect on the West Reef; the banket and quartzite being blackened, greatly indurated, and exceptionally pyritic. The upper portion of the ore near the dike contains more gold than the lower portion, while in the adjacent Robinson-Randfontein mine, where the dike is only poorly developed and is generally absent, the reverse is the case. The undoubted connection between the blackened color of the quartzite and richer ore indicates, as in the case of the black-edged and the pinkish pebbles, that the color is due to the mineralizing solutions, liquid or gaseous, to which the banket owes its gold contents.

This blackened quartzite strongly resembles the very hard, black, crystalline quartzite which in many places³³⁰ is a very characteristic feature of the Black Reef formation. It has already been stated that the color of this latter quartzite is probably due to manganese leached out of the overlying Dolomite. The frequent and well known association of manganese with gold and its presence together with chromium in the black-edging of the pebbles just described suggest that the black coloration in the case of the quartzites associated with the bankets is due to manganese, or chromium, or to both.³³¹

Summary of Parts V and VI

The distribution of the gold in the auriferous conglomerate of the Main Reef series has now been described. Why this particular series was chosen by the mineralizers as the main channels of circulation and of deposition for their mineral and metallic contents has been explained. The fact of the unusual and seemingly wonderful persistence both along the strike and in depth not only of the lode but of that which is of such world-wide economic importance, its profitable ore, has been brought into deserved prominence. It has also been shown that, once the nature of the deposit is rightly understood, such extension of good ore is only a natural result from channels having existed that afforded free circulation, throughout many miles of their length, owing to the fact that the walls were kept apart throughout that length by the intervening pebble beds. It was pointed out that the boundaries of the profitable areas of gold-quartz mines can generally be represented in front elevation by inverted triangles, rarely much elongated in comparison with the length of their bases, sometimes approaching equilateral shapes and often squat. To expect the height of such an inverted triangle to be only one-fiftieth of the length of its base would be altogether unreasonable. Thus, when one considers that the Rand gold-

field consists of adjacent mines (most of which are twin mines, working two parallel lodes) stretching for some 55 miles along the strike; and further realizes that a vertical depth of 5500 ft. is less than a fiftieth part of this length; and again that it has been shown in the case of this particular and abnormal type of deposit, that the limits of its profitable ground should be represented, in section or front elevation, by a rectangular figure and not by a triangle (in other words, its extension along the direction of the strike should be practically as great in depth as at the surface) one can then imagine the enormous possibilities of the deep-level ground and begin to form a clearer idea of the extraordinary extent of the mineralization.

The distribution of the gold among the various banket seams of the Main Reef series, and why it is principally concentrated in certain ones has been discussed. The way the gold contents fluctuate between the two subdivisions of the series has been indicated, and it was shown that this is also quite a usual phenomenon in the case of parallel gold-quartz lodes of normal type. It was demonstrated that shoots do occur even in this deposit, in spite of the free and open passage that was offered throughout to the mineralizers, as compared to an ordinary vein or lode. Also, instances of the influence of dikes on the gold tenor of the lodes were given. Then local indications by means of which relatively good ore can be recognized were summarized and described. The first of these, or the presence of relatively large pebbles, has previously been used as an argument in favor of the theory that this gold deposit is of placer origin. It was shown that it certainly forms an equally good argument in favor of the auriferous banket being an abnormal type of lode deposit. Other indications such as the presence of much pyrite, the so-called pyrite 'pebbles,' carbon, black-edged, black, pink, and milk-white pebbles, and dense black crystalline quartzite have been shown to be due to agencies that have operated after the conglomerates were laid down, such as those with which one is familiar as having often operated in the formation of normal veins or lodes.

The reader who has read all the preceding portions of this paper and has carefully considered the facts and arguments advanced in part V and in this present part will probably have arrived, with the writer, at the conclusion that the facts admit of no other explanation of this enormous stretch of auriferous banket than that it owes its pyrite and gold, in fact its mineralization generally, to those same agencies with which one is well acquainted in the case of normal fissure-veins.

Finally, in the subsequent portion of this paper the genesis of the gold and pyrite will be more particularly considered; and also the agencies that were responsible for the introduction of the mineralizers into the banket. The paper will then conclude with a discussion as to whether the gold in the bedded quartz veins of the Dolomite formation in the Northern Transvaal; in the banket and in the horizontal quartz reefs of the Black Reef formation; and in the banket of the much older Witwatersrand system, is due to more than one or to only one great period of mineralization.

³³⁰For example, in deepest borings on the far East Rand, where it forms one of the hardest rocks encountered by the diamond-drills. In the hand specimen, this quartzite is black in color, heavy, crystalline, granular, compact, and possesses a somewhat saccharoidal texture and breaks with a lustrous fracture. As pointed out by Sir A. Geike (*Text Book of Geology*) (1913), Vol I, p. 250), a lustrous fracture, observable in many quartzites, is doubtless due to the exceedingly firm cohesion of the component grains, which break across rather than separate, and the consequent production of innumerable minute clear vitreous surfaces of quartz.

³³¹Iron may also be one of the coloring agents.

The Glacier Trail to Shushana

The trip inland to Shushana has been one fraught with hardship and difficulties, as is the case in the development of every new district in the north country, and to those who blaze the way and make easier the burdens of travel, special credit is due. A record of the expedition which located and marked the trail across the Nizina and Shushana glaciers is contained in a report made by George C. Hazelet, who was in charge of this expedition, to the Cordova Chamber of Commerce.

Nature of the Trail

The distance from McCarthy to the Shushana 'diggings' does not exceed 75 miles, and that distance can be reduced at least 5 miles when the ice is in the Nizina river, which will be about January 1. The trail at present leaves McCarthy and crosses Sourdough hill to the Nizina river, thence up that river to the glacier. Later, when the river is frozen, the travel will be down the Kennecott river to its junction with the Nizina river. The trail has a water grade from McCarthy to the Hill and McLeod road-houses. From this point it crosses the glacier and the grade averages from 3 to 5% for the next 10 miles. The next mile has a grade from 6 to 8%, and for the following 3 miles the grade does not average 4%. At the end of this last bench of ice the heaviest grade on the route is encountered. There is about 300 ft. of 10% grade, then 1000 ft. of 4% grade, then 450 ft. of 15 to 16% grade, then 300 ft. of 8% grade, and lastly about 2000 ft. of 5 or 6% grade. From here on to the summit, a distance of two miles, the grade does not average 4%. The grades on the Shushana side are better than on the Nizina, because the Shushana river has its source in higher altitudes than the Nizina. The grade for the first 7 miles down from the summit varies from 2 to 5%. A few short heavy grades are found in the next 2 or 3 miles, but nothing a 'rough-lock' will not hold over.

Twelve miles from McCarthy on the Nizina river is the first road-house, known at Clarkin's, and from this point there are road-houses at intervals as far as James Clark's in Pleasant Valley. Beyond Pleasant Valley the expedition established relief tents, which are furnished with stoves and afford shelter. Another house is to be established at 'The Lake' in the last timber at the foot of the glacier, 5 miles from Shushana city.

The relief tents are second-hand tents and somewhat worn, and should be replaced by new tents of 16-oz. duck, the size should not exceed 10 by 12 ft., and the relief tent on the Shushana side should be placed within 2 or 3 miles of the summit instead of where it is now, as there will be a road-house in the near vicinity. These tents are for use only in case of emergency or by persons going and coming from the 'diggings' who are traveling light. It is presumed, of course, that persons freighting will have their own camps. If freighting into the country it is advisable to establish a camp at Mrs. Hill's road-house, the point at which the glacier travel begins, and freight all supplies to Pleasant Valley, 9 miles

distant, then move camp to the foot of the summit, taking a sufficient supply of food for the time required. Send the teams to Pleasant Valley in the forenoon, and put these loads on the summit in the afternoon. When all supplies are on top, break camp, pick up freight on the summit, and drive with the whole outfit to timber on the Shushana side, a distance of possibly 20 miles.

All single tripods or stakes are on the right hand side of the trail, going north or into the 'diggings,' consequently they would be on the left hand coming out; the trail follows them closely, being from 2 to 4 ft. distant. Where there is a turn made or any danger whatever of crevasses, stakes or tripods were set opposite each other, and the route lies directly between. If this is kept in mind, one can travel as safely over this route as over any trail in the country. Where ice was found the stakes were tripoded, tying them together at the top and setting the butts in the ice. Where enough snow was found to hold the stakes, single stakes were used. All stakes are 8 to 12 ft. long and of green willow.

In regard to weather conditions on the trail during November on the glacier, there was no weather or indications of weather equal in ferocity to that on Thompson pass, Marshall pass, or in fact any of the upper regions of the Copper river. Undoubtedly storms sweep over this summit as they do over all summits, but there is no reason why they should be worse here than elsewhere. In fact, it would seem that there is a very good reason why they should not be; this is an interior summit, the temperature is about equal on each side and not subject to extreme fluctuation as is a ridge reaching down to the sea on one side and the interior on the other. However, storms must be expected and a sensible man will prepare for them and not try to move freight or travel when they are on. Every Alaskan knows what is meant, and the 'Cheechaco' will learn.

Many go over the trail with absolutely no equipment. Some come out from Shushana and some go in who have neither food, bedding, snow-shoes, nor even proper clothing. It is only natural that some of them get frost-bitten and report an awful time on the trail. Some have even attempted to travel without bed or snowshoes.

Proper Outfits

What the Government should do, but never has done on any trail, is what the Canadian Government does, place a police officer at each one of the starting points, and see that every man is properly equipped before he is allowed to leave. This would largely avoid the loss of life and prevent much suffering. There has always been a loss of life and much suffering on every new trail; it is a penalty the pioneer pays, but he does not hesitate at that any more than one stops going to Chicago because men freeze to death there. Therefore it is expected that some will lose their lives, others will be frost-bitten, and others will have a terrible time, but if they do, it is all owing to their own carelessness or lack of preparation and good judgment, for there is absolutely no reason why men with common sense, properly equipped, cannot go through to the 'diggings' quickly, safely, and cheaply over this route.

Prospecting Conditions in Peru—II

By CHARLES S. HALEY and C. A. RODEGERDTS

The general distribution of the mining districts in Peru seems to include practically the whole country. In the north, near Paita and Eten, a large English company is busily engaged in developing an oilfield which promises to be one of the largest and most profitable in the world. The oil is high grade, with a paraffin base, is easy to refine, and seems to be very abundant. One company has a concession for exploiting about six hundred thousand acres. Also, in northern Peru, about three days' journey from Trujillo, a French company, capitalized at several millions, has undertaken the development of a large silver and copper deposit. In the same country, Peruvian engineers speak of a network of parallel silver veins, and, a little to the north and west, six-foot seams of anthracite coal, with ninety per cent fixed carbon.

Central Peru

In central Peru, the Cerro de Pasco company is developing large copper properties. Farther south, among the sedimentaries again, there are large bodies of coal, more especially within one or two day's ride of the port of Pisco. To the east of this, again, lie large deposits of low-grade copper. All of the information on this country is very indefinite, and it is hard to get detailed statements, or anything but glittering generalities, from the average Peruvian official. Even their official bulletins share this same tendency.

To the south, in the provinces of Cuzco, Carabaya, and Sandia, lie the ancient gold workings of the Spaniards. Here are in actual operation very few companies, notably the Inca Mining Co., the Ferrobamba Copper, the Rinconaldo (hydraulic gravel), and the Apurima (also hydraulic). The country has been little prospected, but there are several American prospectors who have recently gone in, and who report a promising country. Good looking gold specimens are on exhibition on all sides, but of course this carries little weight with the average engineer. In Cuzco, in the possession of some of the older families, are some very fine emeralds, and even now a few are being mined from an

ancient working of the Spaniards in that province.

In going into the country to look for mining property, however, it will save the engineer much trouble if he does not permit his purpose to be known in the larger cities. In this respect, it is necessary to call attention to a trait not to be commended among the Peruvian engineers. After graduation from a technical school, the average young engineer considers that his career is made, or at least marked. The idea of manual labor, and the four or five years of apprenticeship at the practical side of actual mining and milling, which we consider essential, does not enter into his calculations. Neither does he care for the hardships of prospecting and developing his native country. The great majority of them try to enter the service of the government as soon as possible, and aim to get as attractive a post, in as civilized a locality, as they can. As a result, whatever prospecting is done is either carried on by foreigners (mostly Americans), or the native miners of the interior, who prospect with a view to making their own living out of the results of their operations. The natives of the south seem to be far superior in industry and intelligence to the sheep-herders of the north, and many of them have sufficient initiative to do what the engineers and mining men of the country should do in a more intelligent and effective manner—to prospect properly their own country. As denunciation of a prospect entails a yearly tribute to the government of fifteen soles per pertinencia (200 metres square), and also serves to attract public attention to the location of the property, these native miners are

NATIVE PERUVIAN PROSPECTORS.

AN ANCIENT DITCH.

usually careful to say nothing of any knowledge that they may have. They cannot afford to pay the tax themselves, as they work only on the smallest scale and in the crudest manner, and they do not care to have some local village magnate grab the property.

On the other hand, they have more faith in the honesty of a visiting engineer of English or American blood than they have in their own countrymen, and it is easy to win their confidence. In fact, all that most of them would ask in payment for guiding one, in case of success in finding anything, would be a matter of a hundred pounds or so, and, of course, in case of failure, one would be out nothing but the expense of going on a wild goose chase; something which has to be expected in nine out of ten prospecting expeditions.

Mine Speculators

The engineer, then, if he is really anxious to put in his time to best advantage, will avoid the attractive offers made him by the Limanian and Arequipanian speculators, and go into the country for himself, and make his own acquaintances. In the use of the word speculators, reference is made to a rather peculiar class who seem to abound in these two cities. They are usually local merchants, who keep one or more men in the field all the time, with instructions to denounce property. Almost anything will do, if it is in a country to which interest has been attracted on account of some bona fide operations. The idea seems to be to get hold of some ground, on the chance of disposing of it, in wild-cat fashion, to the Englishman or American, who is supposed to be made of money. To this end, attractive commissions are freely offered to engineers, with the object of a favorable report. Invariably a large cash payment down is expected on property of this class. If the property is examined, it will often be found that the original locator is in considerable doubt as to the limits of his denunciation, has not been on the property or put up a single boundary mark himself, and is prepared to pivot or slide his claim all over the country.

Of course, a sensible man does not care to waste his time in this manner, but they are often so well vouched for, and can furnish such convincing proof of the validity of their claims, that it is hard to decide what to believe. The best way, then, is to believe nothing until you have seen it with your own eyes, and to go into the country and get acquainted with the men who actually know it and have prospected it with their own labor. For this reason, it is advisable that a man have a fair knowledge of both Spanish and Quichua. However, if he can get in touch with the white men who are prospecting the country it will often save him much time and trouble, as most of these are experienced miners from the States, and do not get as excited over a little free gold as the natives.

The great drawback to prospecting is the lack of transportation, the lack of capital, and the constitutional lack of enterprise of the native Peruvian. It is very evident that all development of the natural resources of this magnificent country must come from the outside, and foreigners will, of course, then

reap the greatest of the rewards to be gained.

The general geology of Peru has been very little worked out, and what meagre information exists is largely confined to the government reports. To one who has been accustomed to the thorough and systematic work of our own Geological Survey, these reports and bulletins seem woefully general and insufficient. This state of affairs is, of course, due both to the lack of money to support and pay parties in the field, and to the before mentioned distaste of the Peruvian engineer for the hardships of camp life.

In a general manner, it may be said that the coast region of Peru consists of sedimentaries; sandstones, shales, slates, and, in some cases, limestone. In southern Peru, toward the interior, the erosion by the rivers of the thick bodies of slate has made tremendously steep gorges. These slates show that deposition must have lasted over thousands of years of submergence. To the north, the great batholiths of the Andes are exposed in many of the river courses for miles, and seem to range from granite to diorite. As a result, the overlying porphyries show all degrees of acidity. Columnar basalt lies over weathered phonolite (often mistakenly called tufa in the government reports); and andesite flows, over stream beds, have made lava conglomerates of tremendous size and extent. Quartzite and limestone occur in large bodies. The working out of the details and relations of the eruptive and sedimentary rocks of Peru is a gigantic task, yet one which will be facilitated by the exposures of the formation visible in the wonderfully steep and deep river cañons. In any particular part a person of even moderate geological experience can work out the general relations from mule-back, while riding down the trails through the cañons. The task of working out the formations of the whole country, however, or even of the more prominent mineral districts, is one for the government.

Climatic Conditions on the East Slope

The general discussion of climatic and aqueous conditions in the foregoing has been practically confined to the interior and higher mountain country of Peru. As one goes down from the province of Aymares along the Challhuanca and Pachechaca rivers to the Apurimac (which is one of the headwaters of the Amazon), there is a great change to be noticed. Dropping down off the windswept, bleak pampas above to the precipitous slope of the Challhuanca, an immediate change in climate is noted. Sheltered and protected from the wind and cold by the steep gorge of the river, trees and foliage become more abundant. Parrots fly about one, uttering their raucous cries. Farther down the river, at its junction with the Pachechaca, wide areas of bottom land, carefully planted and cared for, bloom forth into serried ranks of sugar cane. *Haciendas* offer their charming hospitality at convenient distances apart. At Abancay, in the province of the same name, one comes again in reach of the telegraph.

The latter institution, in the interior, is a fearsome and wonderful affair. In the first place, most of the interior lines are the property of the state, and all government business, no matter how routine-like, has the right of way over all private business,

no matter how urgent. From Sandia, about four hundred miles south of Lima, to the latter place, the average time of sending and receiving a message in reply is just about ten days. Messages from Challuanca to Lima sometimes went through in four days. A certain amount of this delay is, of course, due to the natural *manana* spirit of the native operators. Crossing over to the Apurimac from Abancay, the journey is enlivened by pleasant *haciendas* to Limatambo. Here begins another climb up to the pampas of Cuzco, and once on top the going is level and easy until arrival at the latter place.

At this point, memory of an experience beyond Abancay makes a slight digression necessary. Beware of American canned goods and wire nails in Peru. In the one will lurk ptomaine; in the other profanity. For some reason or other, the cast-offs of American trade seem to land in these out of the way localities. An experience with ptomaine poisoning, alone in a little village four hundred miles from a hospital, with no white men or even Spanish-speaking natives around, at the beginning of an examination trip, is not a thing that one cares to have repeated often.

Cuzco

Arriving at Cuzco, one instantly perceives why it has been aptly named the dirtiest city in the world. In a city of forty thousand, without a sewage system, life is not the pleasantest thing imaginable. You will do well to see that your rooms are at least fifteen feet above the ground level. Cuzco is an interesting city, because of the Inca history that centres thereabouts, but as this is a description of prospecting conditions rather than travel, it is sufficient to say that it attracts many of the better-informed class of tourists. A narrow-gauge railroad runs out from here to Sicuani, there to connect with another line—the Ferrocarril del Sur, which runs from Sicuani to Mollendo via Juliaca and Arequipa. In buying a through ticket to Mollendo, by some freak of Peruvian railroad law, you will pay more than by buying to a point slightly beyond Sicuani and then getting out and buying another ticket from that point to Mollendo. This seems strange, but it is true.

Pucara and Tirapata, some distance beyond Sicuani, are the entrygates for supplies for the provinces of Sandia and Carabaya, and, beyond that, the great rubber country of the Madre de Dios. The Inca Mining Co., as before stated, has a wagon-road which runs for nearly a hundred miles to the northeast, and from the end of this road it is possible to go by trail and mule-back clear down to the newly built railroad which comes up through Brazil from Porto Velho. This connection made, the journey across the continent is practically accomplished, as far as difficulty is concerned.

Striking northward from the railroad at either of these points, it is necessary to cross the Cordillera once more. Before reaching Cuzco, the elevation has been over ten thousand, and the country is level pampas, with narrow cañons between low hills to break the monotony. Sheep raising is the principal industry, and the *haciendas* are far apart. However, after crossing the Cordillera somewhere in the vi-

cinity of Poto, an immediate and precipitous descent is made for some six thousand feet toward Cuyocuyo, on the headwaters of the river Sandia, which in turn empties into the Inambari and the Madre de Dios.

From this locality downward you are in a well watered country, with tropical vegetation and frequent and heavy rains. Also, you are in one of the oldest gold-producing districts of Peru. From the stream and glacial gravel deposits of this country came a large proportion of the gold which the buccaneers fought so hardly and so treacherously to gain, during the days of Spain's colonial empire. Worked by slave labor, and with ground-sluicing methods, many of these deposits, though low-grade, paid well. With labor in its present state of unreliability and freedom of a sort, it behooves the engineer to calculate closely.

Wages in Southern Peru

In southern Peru wages are much higher than in the more remote mountain country formerly discussed. *Sindoros*, or trail cutters, who are absolutely necessary to a careful examination of any property, usually cost two soles per day. Skilled quartz miners often run over this figure, and ordinary labor will bring from eighty cents silver to one sole. However, the labor seems to be more efficient and less child-like than that of the higher mountains, save in one respect. That is in regard to alcohol. Frequent religious *fiestas* and holidays give them all the excuse in the world for drunkenness, and although they will contract to work for longer terms than their brothers of the pampas, during certain seasons of the year you cannot get them to work for love or money. Yet, among the better class of natives, there are many shining exceptions, whose faithfulness and diligence in the performance of their duty brings feelings of affection and regret to the mind when leaving them. There is one of this class now in Tirapata who is faithfully anticipating the return of his *Americano patron*.

Sandia, capital of the province of Sandia, on the headwaters of the Inambari, is a centre for outfitting expeditions with mules and men. Food supplies can also be purchased here as cheaply as they can be carried in. The native flour, manufactured by rolling whole wheat between rounded stones, makes a coarse brown bread which when fresh is palatable, and when stale is very durable. On the other hand, white flour, such as is brought from the rolling mills at Callao, costs about three times as much in the interior as the native flour, and does not make a much more wholesome bread, though a little of it for the sake of variety is acceptable.

During the rainy season—the summer months—the rivers in this district are swollen. A river may be a small stream in the morning and then become a roaring torrent before evening. As the principal bedrock of this country is a homogeneous slate, the erosion is marked, and the river cañons are steep. The grade of the rivers is rapid, and, for purposes of hydraulicking, ditches need not be too long. Some of the ancient river channels, of enormous extent and quantity of gravel, are on the edge of cañons cut by present-day streams, with a sheer

declivity of many hundreds of feet. Many of these channels show traces of work done in colonial days by Spaniards, and the ditches dug in those times, sometimes eight or nine miles in length, are still in good repair and need little more than cleaning out to make them available for the use of monitors. Some of these tremendous bodies of gravel show fair prospects, on the surface of the exposures made by the Spaniards. There are also many of the old quartz workings accessible, but they are difficult to prospect or sample, as they need cleaning out and unwatering.

Roads and Trails

The roads and trails in this portion of the country are none too good, especially during the rainy season. Most of them are relics of the old colonial days, and show that in the past a great amount of labor and care has been spent upon them. Winding down the cliffs of the Rio Sandia and the Inambari, on the San Juan del Oro trail, the way rises and falls over many miles, in the aggregate, of painfully built stairs made of slabs of slate placed carefully one above the other. This method of taking grades seems to be acceptable to the mules of the country, though in the rainy season, when the stairs are wet and slippery, the rider risks his neck continually. Heavy packing over this trail is impossible, and a llama can carry much more than a mule in proportion to his size, as he is much more sure-footed.

Further on, one of the cross-country trails leading to the gravel deposits before mentioned, the road is carefully paved with cobbles, all slippery and rounded with age. Each one of these appears to have been carried up from the rivers, in many cases thousands of feet below the trail. The present method of repairing trails seems to be by means of corduroy, made of a heavy palm-like wood that grows all over the mountains in scattered clumps. Climbing up a stairway of this sort is a feat for a toe-dancer, but not proper for a mule.

At intervals along the main routes the present government has caused to be constructed what are called *tambos*. These are rude resting places for the traveler, consisting of a heavily thatched roof mounted on a framework of uprights. In the rainy season they are a welcome sight, although filled with a motley crowd of Quichuas, Aymaras (for this is not far from the Bolivian frontier), and traveling Peruvians.

Feed for one's animals is abundant in this district, and the hills on either side of the main trails are impassable without trail-cutters to carve a way through the tropical growths.

There is quite a variation in the quality of gold that is brought in for examination. Ounce and half-ounce pieces appear to be common in some parts of the country, denoting, of course, pocket conditions, and still, in channels of another age a few hundred feet above, the gold seems to be fine and flaky. The same variation is noted in quartz specimens.

There are several American prospectors in southern Peru, many of whom have prospected all over the United States. They all seem to be enthusiastic over the possibilities of the country, but deprecatory of facilities for operation.

They all refer to the necessity of outside capital, because they realize that, beyond the expenditure of a few soles per year to hold claims for speculative purposes, it is useless to expect the local capitalists to do anything. In this respect the Peruvians differ greatly from their neighbors of the south. Many of the Chileans of moderate means own and operate their own mines. There is a difference in the temperaments of the two races; the more enterprising, on the south, having two railroads to the Peruvians' one.

Almost as much interest has been taken in the mining field of western Bolivia, in the past few years, as in southern Peru. For this reason, it may be well to add a discussion of this country and the means of reaching it. Leaving Mollendo, on the extreme southern end of Peru, about noon, one arrives at Arequipa about seven in the evening, and is glad to rest over night there at any one of the hotels, after a dry and dusty journey. Arequipa is at an elevation of about seven thousand feet. Leaving here in the morning, one arrives at Puno, on Lake Titicaca, at somewhere around ten thousand feet, at seven in the evening. The same evening you go to bed on the steamer, which lands you at Guaque, on the other side of the lake, and on the Bolivian frontier, early the next morning. The train for La Paz leaves shortly after the arrival of the boat, and you arrive there the evening of the second day from Arequipa.

In going up from Guaque to La Paz, you pass through pampas all the way, and reach a height of 15,500 ft. Then you drop gradually down, until you reach Aleo, 500 ft. above La Paz.

La Paz

The approach to La Paz is particularly beautiful. As the train bears you across the pampas, it seems as if you were heading straight for the rocky barrier of the Cordilleras. Of a sudden, the pampas drop away, and you see the town, with its red-roofed houses and shining white walls, directly beneath you in the river valley five hundred feet below. The last stage of the journey down the grade from Aleo is accomplished in an electric train. To the south of La Paz stretches another pampas beyond which are the mountains. Another means of access to Bolivia is the road from Antofagasta, in Chile, built to metre gage, but now being widened to standard. This road also connects by branch lines with Oruro and Potosi. Still another road is now under construction from Arica.

La Paz has an elevation of twelve thousand five hundred feet. There are some small sheep and cattle raisers, but the principal industry of the region is agriculture and mining. Tin mining is predominant, although there are some gold mines; notably, the Chuchuguilla and Hoja de Oro. Ancient irrigation systems from La Paz and Chuchuguilla rivers are the principal support of agriculture, the principal products being vegetables and barley.

The real capital of Bolivia is Sucre, some distance off the railroad, but the government offices and principal officials are in La Paz. Most of the business of the country is conducted there. It is one of the cleanest towns in South America, and quite the prettiest in site and appearance, though not very

large, as it has a population of only about fifty thousand. There are good hotel accommodations. The general attitude toward Americans is friendly, as it is in Peru. The principal English speaking population is made up of English and Germans.

There are many of the old Spanish mines in the neighborhood, but few of them are being worked. There seems to be as much profit in quarrying as there is in mining; one company is blasting boulders in the Chuehuguilla river to supply the demand for crushed stone. Wood is scarce, and is largely supplied by the Yumas Indians, who bring in fruit and firewood from three hundred miles back in the mountains, packing it on the backs of llamas.

With the exception of a few eucalyptus trees that have been planted near La Paz, there are no trees growing. As these thrive there, it seems as if it should be a profitable industry to plant eucalyptus for firewood. At present, the principal fuel consists of pent and llama dung.

Bolivian Mining Districts

The principal mining districts of Bolivia are Oruro, Cochibamba, and Potosi. Oruro, to the south of La Paz, is reached from Biachi, on the Antofagasta line. It is nearly a thousand feet higher than La Paz, and is in the heart of the mountains. Most of the mines are tin and copper. The copper mines are near the town, but are mostly small. Oruro is the best town to outfit in, in the country. Goods come up directly from Antofagasta, and do not have to be transhipped, so are cheaper than in any other place. Mules are rather high, costing from twenty to forty pounds.

Potosi is reached from Rio Mulata, between Oruro and Antofagasta. As there is only one hotel here, with four rooms, it behooves the wise traveler who has to stop over night to engage accommodations in advance. A train runs to Potosi three times a week. The road is at present run by the contractor who built it, as his grades were too high for the Antofagasta people to accept it. The altitude of Potosi is 14,000 ft. It has rather a cold climate. Potosi hill is famous for the number of mines that have been worked there. At present there are some two hundred and fifty in operation. They are mostly small concerns, working the old dumps for tin. There is also much copper and silver in the ores.

The principal source of labor is found among the Aymaras, or Bolivian Indians, who much resemble the Quichuas of Peru in facial characteristics and in disposition. The dress is similar, consisting of the inevitable *puncho*, short tunic, trousers, and leather sandals. One marked difference from the Quichuas is the trousers, slit to the knee, the result of an ancient pledge to wear them so until the race should be free from alien domination.

In character, the Aymaras are generally peaceable, bovine in temperament, disposed to get drunk, and hold religious festivals even to a greater extent than their Peruvian brethren, the Quichuas. They speak an entirely different language from the latter.

Summary of Mining

In summing up the general situation with regard to the mining industry of this part of South America,

a few brief generalizations may advantageously be drawn. In the first place, there is no question but what an immense store of wealth has already been taken from the countries mentioned in the past four hundred years, mostly by the crudest of methods. For this reason it seems that improved methods and machinery should bring forth even more notable results. On the other hand, it should be remembered that most of the deposits were worked by slave labor, and that because of this an element which must enter into modern calculations to no slight degree was altogether lacking in the expense accounts of the Spaniards.

It is also said that the Spaniards, holding the country for so long, worked out the best of it. The falsity of this assumption, however, is apparent on the surface to anyone who has seen how superficially some of the *antiguas*, and, in fact, the larger number of them, have been worked.

As yet, very little information is available as to the possible mineral resources of this vast mountain country. Owing to the poverty of the governments dominating it, and the natural inertia of the people as a whole, a beginning has not been made in the prospecting of it. From the time of the independence of the colonies, near the beginning of the nineteenth century, the traces of Spanish operations have been gradually eroded and hidden from view by nature, in many cases supported in her efforts by a prodigal vegetation. Railroads are few, roads fewer, and trails in many cases all but impassable. Jungle growth and mountain torrents impede investigation of one of the most promising districts—that of southern Peru. To the north, the lack of water is as great a drawback as it ever was to the prospecting of Nevada.

Still, the dominant genius of the Anglo-Saxon is meeting these obstacles today, and with the guarantee of a stable government and full protection for invested capital, will continue to meet them with increased vigor. Whether the Latin races who control the country will sufficiently take pattern to develop their own resources for themselves is hard to say; they have not done so in the past. There is one Spanish word which is much used in editorials and political discussions, but whose meaning seems to be lost sight of in actual practice—*aprovechar*—to take advantage of. Peru, now one of the poorest governments, is potentially, by reason of her immense mineral resources, the richest of the Andean countries, but cannot take advantage of them.

The country is all right. It is destined one day to be one of the richest in the world. What it most needs now is wise exploitation, scientific prospecting, and the careful expenditure of capital. Wild-cat dredging schemes have already threatened to do infinite harm to the reputation of a good gravel country.

Speculators of all nations, unscrupulous and avaricious, await the footsteps of the intending investor in this as in all countries. These should be absolutely avoided, and careful personal investigation of the country should be made even before sending out examining parties. In this way, one man, or two, can often save the waste of time and traveling expenses of eight or ten. The game is worth the

candle, in this, one of the last of the world's great treasure houses.

As an illustration of the Latin temperament, in Sandia, last January, the mule which carried out the weekly mail to Pucara, on the railroad, was overloaded, by his too ambitious master, with way freight. He fell down on the trail between Sandia and Cuyoeno, and had to return to the former place. On hearing this, I remarked, with regard to a letter of some importance, "Well, I suppose that the mail will not get out till the morning."

Turning his surprised and reproving gaze upon me, an old gentleman remarked, reproachfully, "*No, señor, no es posible que partira el correo mañana. La mula necesita descansar una día o mas.*" (No, sir, it is not possible that the mail will go out tomorrow. The mule will have to rest for a day or more!)

An Electric Time Fuse

By E. LE ROY

In reading the interesting article on 'Electric Blasting,' by Charles H. Hurter, in the issue of the *Mining and Scientific Press* of November 8, I call to mind an electric fuse I have frequently employed in drift as well as in shaft work, and as the idea is, I think, original with me, and may be of use to others, I will give a description of it. The electric time fuse, as described herein, consists of a short piece of ordinary fuse, with an electrical

FIG. 1, 2, AND 3.

means of ignition, and is made by splitting the ends of the fuses in the usual way, and each to the same depth, and into the bottom of the cut drawing tightly a short bit of either iron or german silver wire of small diameter. The former is as good or even better if a lighting current be available for blasting, but if a blasting machine is to be used, the german silver wire is better. Allow the excess powder in the split portion to fall over it, and take a half-hitch or loop around the fuse just below the bottom of the cut, leaving about two inches extending to connect with the copper leaders, which can be double cotton covered and paraffined annunciator wire, double conductor bell wire, or any insulated copper wire of from No. 18 to No. 22 gauge. Loop the other end around the fuse in the opposite direction and just above the cut, or say $\frac{1}{2}$ in. above the first loop, and be sure that the loops do not touch each other at any point (this loop is, of course, on the opposite side to the former one, as in Fig. 1 and Fig. 2). Next connect the copper leaders very close to the fuse, taking notice

that the loops are not short-circuited by them; that is, that one leader does not come in contact with both loops. Cut the fuse to the desired length, and wrap tightly with electrical tape; adjust detonator, and the fuse is complete, as in Fig. 3.

In adjusting for length, allow one-third to one-half inch for every fuse, or every series of fuses, if it is desired to have all the holes of a series go together. The shortest one of the round should be two inches over all. If used in very wet ground, or with water tamping, it is a safer plan to dip fuse, cap, and a few inches of the leader in P. & B. paint or some similiar waterproofing paint that will dry quickly.

The above description, like that of many simple things, sounds somewhat complex, but the fuse is vastly easier to make than to describe. In fact, after a few hours trial, a miner will make 20 complete fuses per hour, and with more experience an even larger number will be turned out. All that can be said, as regards safety, of the ordinary electric fuse, applies equally with these, and, besides, these have the advantage of permitting any order of firing that the miner desires, and with perfect safety, which is the great thing in their favor. In cost, too, they are no more expensive than other forms of firing. In fact, they are even less expensive, for, when properly made, there are no missed holes to dig out and blast again, with the necessary loss of time.

As the loops are short-circuited upon themselves, the only part of the resistance wire to become heated on the closing of the firing switch is the very short piece passing through the fuse from one lead to the other. If a lighting circuit is available for firing, an almost unlimited number of holes can be fired simultaneously; that is to say, ignited simultaneously, and fired in accordance with the length to which they have been cut. In using a firing magneto (often called by the miner a 'battery') not quite so many holes can be fired as the rating of the machine would indicate, even though very fine german silver were used.

With a variation of one-half inch in the lengths of the fuses, the reports follow at about the right intervals for easy counting, and with perfect accuracy as regards this interval.

The Government of India has appointed a commission to consider the standardization of Indian weights and measures, an operation which, if carried out successfully, cannot fail to be of great assistance to internal trade. Its desirability is shown by the fact that the maund* of sugar weights 48½ seers in Cawnpore, 40 in Muthra, 72½ in Gorakhpur, 40 in Agra, 50 in Moradabad, 43¼ in Saharanpur, 50 in Bareilly, 46 in Fyzabad, 48½ in Shah-jehanpur, and 51 in Goshangunge.

The mineral production of Massachusetts in 1912, consisting mainly of stone, clay products, and lime, amounted to \$6,654,514. The value of the stone produced, 60% of which was granite, was \$3,663,279.

*A maund is a weight used in India, Persia, and Turkey, and varies from under 19 to 163 lb. avoirdupois. The Indian government standard maund is 82.28 pounds.

Transporting Coal in China

The illustration on the left shows a typical scene at the mouth of a coal mine in North China. The coal is being sorted and loaded for distribution by carts and pack-animals; some of the output of this mine is transported over 200 miles in carts. Every bit of the coal is sold, and there are no slack dumps. Most of the fine coal and waste is crushed, mixed with mud, pressed by hand into the shape of balls, and dried in the sun. This has been done from time immemorial, and is undoubtedly the first form of briquettes ever employed. The first use of this form of fuel is commonly, and erroneously, ascribed to the French. The central illustration shows a train of pack-mules, loaded with anthracite coal, entering a ferryboat. Rivers are numerous and swift in the mountainous regions of North China, and where the streams are too deep for fording, recourse must be had to flatboats, which are secured by a cable fastened in the middle of the stream, and swing, like pendulums, from bank to bank. The right-hand illustration shows an empty pack-train returning to a coal mine. The paved roadway indicates the amount of care which has been expended in constructing trails, usually following the courses of streams, in the mountainous country.

The lower illustrations show the mouth of a typical native mine; the baskets which serve for the underground transport of the coal are seen at the right. Wherever possible mining is done through

entries, the seam being followed down until the amount of water encountered becomes too great to be handled by bailing it out. In some cases a series of niches is cut in the foot-wall, the water being scooped up in gourds or baskets and thrown into the next niche above. With a series of men, one at each niche, a large quantity of water can thus be removed daily. Where less water occurs it is carried out to the surface and in some places the coal is only mined in the dry season when there is but little water to contend with. The coal is broken down by cutting it with a pick and is loaded into the sled-like baskets, which are drawn to the surface by a line attached to a head harness, much like a 'tump-line.' The workings are kept as small as possible to save the expense of timbering, and progress through them is difficult to the uninitiated, especially as they frequently extend for thousands of feet. The basket is sometimes shod with steel runners, as in the illustration, but is more frequently simply provided with bent pieces of the hard outer bark of the bamboo. The man pulling the basket leans over, touching the floor lightly with his hands, and travels with astonishing rapidity. The boy is about 12 years old, and it will be noted that the roof is just the height of his shoulder.

Uranium pitchblende containing 30% of oxide is quoted in Germany at 81c. per pound.

Mineral output of Maryland in 1912 was valued at \$10,916,671.

Copper Matte and Base Bullion From an Electric Spelter Furnace

By E. W. HALE

In smelting the complex zinc ores of the Western states, the possibility of securing retort residues valuable enough to pay for a second smelting by reason of the lead, copper, silver, and gold left in them, is always kept in mind. Roughly speaking, 60% of the lead and silver, and 75% of the copper and gold present in the raw ore, may be found in the residues if care be taken in treatment. This offers an attractive margin of profit in some ores, and in others may even determine their marketability as zinc ores.

An axiom of retorting practice is 'the lower the zinc assay the higher the zinc loss.' Certain figures are fairly well fixed as losses incurred in smelting and that cannot be avoided. It can be readily seen how a low-grade ore offers small attraction to the smelter, as this fixed loss represents more and more of the total percentage of zinc present as that percentage decreases. But low-grade ores may often become attractive by reason of their lead, silver, copper, and gold content, and may show a profit to the smelter in spite of excessive zinc losses incurred in their treatment. For this reason it is sometimes difficult to say just where a zinc ore ceases to be a zinc ore and becomes a lead-silver ore, judging merely by commercial potentialities.

Complex Sulphides

The advent of the complex Western sulphides into the retort plants of the Middle West used to treating the high-grade Joplin ores containing about 60% zinc and 2% iron, brought with them many changed conditions. Retort consumption that had for years rested comfortably upon a daily average of five or six to the furnace, jumped to 20 and 40 when these ores carrying 35% zinc and 25% iron were introduced. The zinc losses in treatment doubled or even trebled over the old Joplin figures. But in spite of these apparently staggering wastes, the smelting of these ores was highly profitable from the start, helped out in no small degree by the value of the residue. Time and experience gradually brought the process more within the bounds of reason, a condition that proved of advantage to the miner as these ores became more sought after. No recoveries on these high-iron ores were ever made, or for that matter are ever likely to be made, in a retort that compares with the old Joplin practice. Their lower tenor of zinc must always act as a bar to this.

To obtain a return from his residues the smelter was confronted at the outset by a fixed cost that ran about as follows:

Freight to re-treatment smelter (Colorado).....	\$2.00
Treatment charges	3.00
Cost of handling	0.50
<hr/>	
Total cost per ton	\$5.50

Adding to this the penalties for whatever of excess silica, zinc, or sulphur might be present enabled him to figure his possible profit.

In order to enhance the value of the residue, many measures were tried. The residues coming from the retorts contain, as a rule, 30% of carbon in the form of unburned coal. Freight and treatment charges upon this ingredient is, of course, a needless expense. Screening out the coarser particles, which removed about 40% of the bulk even though it took away some of the metal, was the first step, and is the one most generally used even today. Crushing and jigging or tabling the residues, or merely washing out the coal, have also been tried. Another method much used is to 'heap roast,' in which treatment the carbon is burned off and the bulk decreased by blowing a current of air for a month or six weeks through a large heap of cinders. Although most of these methods show a profit due to the enhanced value of the residue, the fixed charge of freight, plus treatment, plus handling, remains stationary and has to be met by each ton of material finally shipped for its second treatment.

A composite sample of slag from 104 taps and representing 16.9 tons of material in the period June 1912 to June 30, 1913, on complex lead-silver-gold-copper-zinc ores shows:

Copper	0.065%	electrolytic assay on a 5-gm. sample.
Silver	0.500 oz.	on a four assay-ton sample.
Gold	0.010 oz.	on a four assay-ton sample.
Lead	0.050%	wet, on a 5-gm. sample.
Zinc	5.250%	

Samples of matte and bullion made in the same period and the ores from which they were obtained are:

	Copper matte.	Base bullion.	Ore.
E. F. 24, run 2....	9.67% Cu	2.25% Cu
	6.12 oz. Ag	0.48 oz. Ag
E. F. 25, run 1....	4.40% Cu	0.62% Cu
	14.00 oz. Ag	2.10 oz. Ag
E. F. 25, run 2A*.	98.70% Pb	14.10% Pb
	0.72% Cu	1.81% Cu
	0.00% Zn	15.60 oz. Ag
	138.20 oz. Ag
E. F. 25; run 2B*	25.00% Fe	98.50% Pb	13.70% Pb
	13.00% Pb	1.00% Cu	1.70% Cu
	15.90% Cu	114.80 oz. Ag	15.60 oz. Ag
	24.00 oz. Ag	1.20 oz. Au
E. F. 25, run 2C*.	22.00% Cu	97.60% Pb	3.50% Pb
	21.80% Fe	0.60% Cu	0.25% Cu
	9.00% Pb	96.00 oz. Ag
E. F. 25, run 3....	19.80% Cu	98.50% Pb	11.75% Pb
	31.00 oz. Ag	40.00 oz. Ag	1.68% Cu
	0.02 oz. Au	31.20 oz. Ag
	0.48 oz. Au

*As runs 2A, 2B, and 2C are but periods of the same run, it was impossible to make a sharp metallurgical cut-off, hence part of the copper, lead, and silver charged in the second run was not recovered until during the third, although charged against the second.

In order to obtain all the metals present in one smelting and in one furnace by aid of the electric current, certain details of construction and operation must be introduced that are at a decided variance with the older retort practice. The formation of a copper matte in the furnace necessitates

the presence of a certain amount of sulphur depending upon the amount of copper and iron present, and does away with the necessity for a 'dead roast' prior to treatment. The fact that sulphur is a necessity is a decided advantage over the retort process. The iron present is not an enemy to be feared any longer, but a useful friend for forming slag, and the lead settling to the bottom of the furnace carries with it the silver and gold. The copper matte resting above this base bullion separates cleanly from the slag which lies above it.

The unavoidable waste of residues occurring in 'blowing out' the retorts, screening, loading, and transporting the shipped material when they are sent to a second smelter for treatment must be considerable, although no figures can be available. The electric furnace accounts for everything put into it, and, as the expression has been used, 'is metallurgical addition instead of subtraction.' It is quite within the bounds of probability to treat an ore in the electric furnace that would be desirable in no other, one that would carry a penalty for zinc if sold as a lead-silver ore, or a penalty for lead if sold as a zinc ore. The idea of a metallurgical scavenger thus feeding upon the undesirable ores of the far West and turning out the different metals collected, separated, and in marketable form is appealing quite distinct from the rather unattractive simile.

Hoisting at the North Butte Mine, Montana

An electric hoist with a capacity of 300 tons per hour from 2000 ft., and 200 tons from 4000 ft. depth, and one of the largest in the world, is to be installed at the new Granite Mountain shaft of the above mine. The present depth of this shaft is 2900 ft., and skips holding 7 tons of ore each will be used.

The system of control and power equalization used will be that commonly known as the Hgner system, in which a fly-wheel driven by the motor-generator set is permitted to give up some of its stored energy to supply the peak load drawn by the hoisting motor. In order to reduce the fly-wheel losses to a minimum, the fly-wheel will be encased in a smoothly finished steel housing, and provided with special type of self-lubricating bearings.

The hoisting drums, which will be 12 ft. diameter, will be driven by a direct-connected electric motor running at a speed of about 71 r.p.m. Power will be supplied to this motor from a motor-generator set equipped with a 50-ton fly-wheel to secure elimination of the peaks that would be drawn from the power line during period of starting and acceleration. The hoisting motor will be of the type used in steel mills, of very heavy construction, and will have a maximum intermittent rating of 4500 hp., and the motor-generator set will be driven by an induction motor having a continuous normal rating of 1400 hp. The difference between these ratings represents approximately the amount of energy that will be supplied by the fly-wheel momentarily, during starting. The installation is so designed that the draft of power from the power-line will be practically constant throughout any cycle of hoisting.

Hoisting with this equipment will be done in balance, but it is large enough to take care of unbalanced hoistings. Round rope, 15/8 in. diameter, will be used, and the engine is designed for a normal rope speed of 2700 ft., with a maximum of 3000 ft. per minute.

A number of special safety devices are included in the equipment, including electrically released brakes; automatic slow-down devices to prevent skip or cage going through head sheaves and a special controller to limit the speed when hoisting men. The electric plant alone will weigh over 250 tons. Some high economies have been guaranteed on this installation by the Westinghouse Electric & Manufacturing Co., and this installation will be watched with interest, particularly with a view to comparing its economy with that of the pneumo-electric hoisting system designed by Bruno Nordberg, being used at ten of the Anaconda mines, at Butte.

Preparation of Primers

A recent publication of the Bureau of Mines states that miners should cut off and throw away an inch or two of the fuse before inserting it in the detonator, for gunpowder easily gathers moisture, and the end of the fuse may have become damp enough to quench the burning powder or prevent the ignition of the detonator. Insist that this cut be made squarely across the fuse with a sharp cutting tool; if the cut is diagonal the point may curl over the end of the fuse when it is inserted in the detonator and thus prevent the spit of the powder from reaching the mercury fulminate in the detonator. If the tool is dull, the powder grains in the end of the fuse may be spilled during the cutting, thus weakening the force of the spit into the detonator and possibly preventing its ignition. The free end of the detonator should be crimped around the fuse tight enough to hold the detonator and the fuse together, but not tight enough to cut off the powder train in the fuse. For this purpose use nothing but the proper crimping tool. After crimping, the detonator should be buried in the end of the stick of dynamite with its axis parallel to that of the stick and its top flush with the top of the dynamite. If the detonator is buried deeper, or if the fuse is laced through the cartridge, the explosive is liable to become ignited from the side-spitting of the fuse before it is properly exploded by the detonator. This not only reduces the efficiency of the explosive, but creates a larger volume of gases which are dangerous to the men who must breathe them. Detonators of sufficient strength should be used. Although No. 5 detonators are considered strong enough for straight nitroglycerin dynamite, the less sensitive gelatin dynamite requires a much stronger detonator to explode it properly. For this reason nothing weaker than No. 6 detonators should be used with gelatin dynamite. Universal experience has been that better results have been obtained with all dynamites when strong detonators are used.

Minerals carried by all railroads in Great Britain totals over 400,000,000 tons yearly.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Geological Survey of China

The Editor:

Sir—In your issue of November 8, F. Lynwood Garrison, reverting to your editorial of June 28, emphasizes the need of a Geological Survey in China. This step I consider premature.

There is a far more pressing need, in that country, for an increased internal revenue, and the time would now appear opportune for China to follow the counsel of her able foreign advisers. China should revise her mining laws, and establish an efficient department of mines, so as to attract foreign capital to that country, thereby creating a source of revenue which could, eventually, be devoted to defraying the heavy cost that a geological survey would entail.

But, as one who has resided many years in that country and is well acquainted with all classes of Chinese, I fear it is too much to hope for a revision of the mining laws favorable to foreigners, as the anti-foreign feeling which, for the moment, is dormant, will again awaken, as soon as any laws framed to benefit the foreigners are contemplated, and no permanent good is likely to result to the nation so long as the people remain suspicious, not only among themselves, but of foreigners in particular.

HENRY BRELICH.

London, November 27.

Pachuca Tanks

The Editor:

Sir—I read with interest Mr. Irwin's letter in your issue of November 22, in which he shows that Pachuca tanks can be started up without trouble after a long shut-down. I find that some complain of difficulty in starting the agitator in these tanks. The only explanation I can think of is that they are not installed properly.

Pachuca tanks were first used by me (1903) for agitating tailing dredged from a river and reground in a tube-mill, and as all the natural slime had been washed away from the tailing by the action of the river and the regrinding did not produce much actual slime, the material was very difficult to agitate. The process employed was decantation, and after each agitation the charge of 50 tons was allowed to settle 12 to 20 hours and agitation was always started up again within a half hour, and by dropping a lead weight attached to a cord, to the bottom of the tank, it was found that no sand was lodged on the sides of the cone after the agitator was well started.

The severest test, in my experience, that a Pachuca has had, was in agitating concentrates. A tank 37 ft. by 7 ft. 6 in. was used. About 50 tons of concentrate was put into the tank and allowed

to stand for 10 days. I succeeded in getting the charge into perfect agitation in about $\frac{3}{4}$ hour.

The chief advantage of the Pachuca, or at any rate one of its strong points, is that if it is correctly designed for the ore to be treated, and properly installed, it is always a simple operation to start it up, no matter how long the charge has been allowed to settle.

Boise, Idaho, November 25.

Professional Ethics

The Editor:

Sir—Mr. Lilligren's solution of the ethical problem given in your issue of November 22, I regard as wholly sound and satisfactory. It agrees with what I had in mind in writing the second paragraph under 'Complications and Embarrassments' in my article on professional ethics in the *Transactions* of the American Institute of Mining Engineers, Vol. XLI, page 559.

Now Mr. Lilligren is so clear in "sweeping aside technicalities and doubts," I should like to have his view regarding the succeeding paragraph of the above-mentioned article. It reads (page 559):

"The right to sell information to another, where the first employer has hopelessly failed to pay his bill, raises a fine point; and this is further complicated if a small advance payment on account has been made. The law and the equity might conflict."

I once had the following experience: Several men were jointly interested in an examination which I made, but they were not the owners of the property. One of them paid his share of the bill, one-third, and received the report. The other partners did not pay and were insolvent and irresponsible. Later another party was anxious to get the information, and the mine was not accessible for another examination. The man who had paid his part refused to pay, or to guarantee, the balance of the bill, and, at the same time, refused permission to sell the information to others. Was I justified in saying that he should do either the one or the other?

VICTOR G. HILLS.

Denver, Colorado, November 28.

Electric Smelting of Copper Ores

The Editor:

Sir—We have read with interest your editorial in the *Press* of November 1, on the 'Electric Smelting of Copper Ores.' Four main questions are brought up for discussion in the editorial which deserve comment: (1) the effect of power cost upon the adoption of electric smelting in the metallurgy of copper; (2) the heat efficiency of the electric furnace as compared with the blast-furnace; (3) the impossibility of using refractory linings in the construction of a copper blast-furnace, because of the necessity of frequent barring down of crusts; and (4) the volatilization loss of 1% of the copper present in smelting native copper concentrates containing about 30% copper.

The Bureau of Mines is gathering data and experimental results upon questions (1) and (2), namely, power cost for electric furnaces and heat effi-

ciency, which it hopes to publish as soon as the required information is made complete.

In reading your statement regarding the incompatibility of the use of refractory linings in a smelting furnace where it is necessary to bar down crusts as in the copper blast-furnace, we feel that there is an inference that a water-jacketed shaft would not be used in the electric furnace as in the ordinary blast-furnace. To clear up any doubt on this question, we quote from our paper on 'The Smelting of Copper Ores in the Electric Furnace,' page 2139 of the August *Bulletin* of the American Institute of Mining Engineers, where it is stated: "To begin with, let us assume that our furnace is similar in construction to a modern copper blast-furnace, and that the upper part of the furnace, including the tuyeres, is practically identical with the same. Below the tuyeres the furnace could be constructed as shown in Fig. 3. By referring to this, it will be noted that there are electrodes extending down into the crucible, the arrangement of which along the sides of the crucible, can be noted by referring to the plan of the furnace in Fig. 4." The shaft of the electric shaft furnace proposed by us for copper smelting, is thus water-cooled and made of water-jackets as in the blast-furnace. This shaft is set over a crucible, as is the case in the Swedish electric pig iron furnace; but differs from the Swedish furnace in that it is rectangular rather than circular in cross-section. Only the crucible of the proposed furnace, described in our paper, is lined with refractory material, and is also covered by a roof of refractory material at the sides. The walls of this crucible could be made of water-jackets, if the electrodes were insulated from the shaft walls and crucible walls by a roof of refractory materials. There is, however, no need of adding this complication to the electric furnace, as no crusts could possibly occur that far down in the furnace. The refractory lining of the crucible would easily stand the ordinary wear on it, as has been found to be the case at Trollhättan. In the electric furnace used in ferro-alloy and calcium carbide manufacture, there is a tendency for the material to freeze on the refractory lining to such an extent that eventually the charge itself really forms the lining of the furnace. Furnaces have been run for two years without being relined. In some works, when the charge does not chill enough to form a protective lining, a water spray is played on the steel shell of the furnace, or in some cases the crucible is water-jacketed, but in most plants this practice has been discontinued on new furnaces, which are designed with the electrodes at sufficient distance from the walls to keep the material frozen on the walls of the crucible.

On page 2124 of the paper above referred to, we have stated in conclusion: (2) "The percentage of copper in the slag need not exceed 0.25, with a slag of proper composition. The loss in the slags should not exceed 0.5% of the total copper charged. Other losses should not exceed 1%, giving a total loss of 1.5% of all the copper charged." In your editorial you state that the loss of copper by volatilization was 1% of the copper present. The 1% representing "other losses" does not consist alone of a volatilization loss. It includes volatilization, oxida-

tion, hangings of partly fused ore and dust loss, which includes both the fine material lost in mechanical handling of the fine concentrates at the furnace, and the dust blown out of the furnace by the gases. In the operation of a small furnace there is considerable mechanical loss by hanging and blowing out of fine material by the gas. In our experimental work these two factors seemed to be the chief cause of copper loss, and we found it impossible to separate these losses, because of the small working scale of the experiments.

We appreciate very much the friendly criticism expressed in your editorial, and merely wish to correct any mistaken impression which may have been given in reading our paper. We hope in a short time to present the detailed results of the experiments which have been carried out to date.

DORSEY A. LYON.

ROBERT M. KEENEY.

Pittsburgh, November 10.

[We are glad that our editorial comment has evoked such interesting additional information of the points of leading interest to the operating metallurgist. The important data and experimental results on the efficiency and power cost of electric smelting which are promised will be awaited with keen interest by all.—EDITOR.]

Work at Cucaracha Slide, Panama

Dipper dredge *Mindi* and ladder dredge *Marmot* are operating steadily on the slide. The hydraulic excavating system which has been sluicing material from the top of the slide north of Gold hill, back into the valley to the east, away from the canal, since June 16, has been extended, so that the monitors may cut through a saddle south of Gold hill and assist in handling some of the material involved in Cucaracha slide. A relay station on the southeast slope of Gold hill at elevation 425 ft. above sea-level was placed in trial operation on November 6, and has since been supplying a monitor on the east slope of the saddle with water at a pressure of 150 lb. per square inch. The flume from the Cucaracha saddle disposes of the spoil in a valley with a general elevation of about 250 ft. above sea-level. The outer edge of the slide at this point is about 565 ft. above sea-level, 1800 ft. east of the centre line of the canal, and it is estimated that between 1,000,000 and 1,500,000 cu. yd. of material can be sluiced away from the Cucaracha slide area. After the limit of practicable outward sluicing has been reached, the equipment may be used to wash material from the face of the slide down into the canal, to be handled by pipeline suction dredges, and clean away the loose earth until a firm face of rock is exposed.

Total excavation by Americans in the Canal, to November 1, 1913, was 212,625,216 cu. yd., and ground remaining to be removed amounts to 19,727,784 cubic yards.

Recovery of copper at the Great Fitzroy mine, Queensland, by flotation is 87%, and of the gold, 72 per cent.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Hoisting men in mines should not be done at a greater speed than 1000 ft. per minute.

Building or mine timber which has been seasoned by natural processes lasts longer and is more reliable than that seasoned artificially.

Gatun lake, in the Canal Zone, lacked 6½ ft. of its normal height of 85 ft. on November 17, and it is expected that this figure will be attained by the end of the current year.

Telephone, telegraph, and power transmission poles in the United States are procured from forests of northern white cedar, western red cedar, chestnut, yellow pine, and juniper. An acre of forest gives an average of 40 poles.

When using a pump during shaft-sinking, the disposal of the exhaust air or steam sometimes causes trouble. To overcome this, and have a quiet shaft and less annoyance to the miners, it is a good plan to exhaust into the water column going to the surface or elsewhere.

To prevent tools or other material lying around the collar of a shaft from being kicked down and perhaps injuring men below, toe guards should be provided. At many iron mines in the Lake Superior district all platforms are completely protected with this simple device.

Connected with the Copper Queen reverberatory furnaces is a dust chamber of 1200 sq. ft. cross-section and 132 ft. long, from the roof of which are hung 30,000 wires. During a period of 13 months only 9 tons of dust was recovered from the chamber. The chamber connected with the McDougall roasting plant is 1370 sq. ft. in cross-section and 144 ft. long, there being 42,000 wires hanging from the roof. So far the dust recovered is 6% of the charge roasted.

Regarding the type of material used in belt-conveyors, it may be said that for flat belts to handle dry material which is not of an abrasive nature, balata belts are very satisfactory; for troughing belts, to handle rough, sharp, or wet material, experience has proved that a good rubber belt with plenty of rubber cover on the carrying side is most suitable. This is due to its flexibility and, when constructed with proper rubber cover, to its abrasion-resisting qualities.

An aerial tramway 37½ miles long is to be constructed from Mariquita to Marriazares, across the Andes mountains, South America. It will be an extension of the ropeway operating from Ladorado to Mariquita. There will be 12 sections, every two sections to be motor driven, power to come from a new hydro-electric plant near Mariquita. Steel towers, varying from 40 to 125 ft. high, will carry the

rope. The altitude will be 11,000 ft. above sea-level. Structural material is being made in the United States, and steel cables and power equipment in England. Sir Douglas Fox, of London, is the designing engineer.

Concrete laid in the Panama canal locks and auxiliary works up to November 1, 1913, was as follows:

Gatun locks	2,050,193
Gatun spillway	230,443
Gatun hydro-electric station	7,295
Gatun duct line	1,919
Pedro Miguel lock	911,851
Miraflores locks	1,487,650
Miraflores spillway	73,497
Pedro Miguel-Miraflores duct line.....	4,616

Total 4,767,464

Cyaniding on a commercial scale was first accomplished at the Crown mill, Karangahake, New Zealand, in 1889. The ore from that mine contains gold and silver, the total output to September 1913 being \$4,130,000. At present the mill is only treating about 1400 tons of \$8 ore per month. An interesting system of treating the battery pulp is in operation, the ore being crushed in cyanide solution by stamps, then further reduced in a tube-mill, the pulp flowing in a launder to a series of vats 22 ft. in diameter. These are fitted with the usual filter bottom. The pulp is run into a vat until full, and then diverted to another until full, and so on, several being charged in rotation, and by the time, say, No. 5 was full

CROWN MILL, KARANGAHAKE, NEW ZEALAND.

the first one would have settled. The clear solution is siphoned off from each in order, then more pulp added to the series, four or five times being sufficient to fill a vat with 40 tons of ore to 3 ft. depth. During this time, a drain cock under the filter is left open, to carry off solution filtering through to the bottom of the vat, this solution being saved, of course. Each charge of mixed sand and slime in the vats is given a strong cyanide solution, then weak washes and water, these being helped by the aid of vacuum pumps and solution cylinders. Rich solutions are filtered and run through zinc-boxes as usual. Time taken in treatment occupies up to 5 days, and contents of vats are sluiced out. This process has given satisfactory results, and may be called a crushing in solution-decantation-leaching system. The mill is driven by a Pelton water wheel.

LONDON

ORE TREATMENT AT THE GEEVOR PLANT.—CARN BREA AND BOTALLACK

Cornish mining has been very much to the fore again this week, and a number of incidents have attracted attention. Among the profession, the incident that caused greatest interest was the attack made by Oliver Wethered on Horace G. Nichols, at the meeting of the Institution of Mining and Metallurgy. Mr. Nichols had presented a paper describing the results obtained at the Geevor tin-dressing plant, near Land's End. Mr. Wethered is chairman of the Geevor company, and is a financier who has introduced considerable London money into Cornwall, beginning with the Dolcoath twenty years ago. After the details of Mr. Nichols' paper had been discussed at the meeting for two hours, Mr. Wethered, who was present by invitation and not by right, got up and denounced Mr. Nichols for unprofessional conduct in that he had written the paper without his permission; not only so, but the plant described had been swept away by the board of directors and Dolcoath practice substituted. This incident was taken by the meeting as a dramatic denouement, and, as neither the president nor Mr. Nichols had the presence of mind necessary in time of crisis, down came the curtain. But in justice to Mr. Nichols, the matter must not be left there, and I will give the facts of the case, with an outline of the paper.

Mr. Nichols had been commissioned by the directors of the Geevor company last spring to ascertain the results obtained by the plant, which had been designed by R. Gilman Brown and W. C. Madge. Mr. Brown was technical director of the Company. These engineers had desired to try modern inventions connected with grinding, classifying, and concentrating, with the object of testing the principle of step-grinding and step-classification as applied to tin ores, hoping thereby ultimately to increase the percentage of recovery, which is admittedly low in Cornwall. The paper presented by Mr. Nichols gave the results of his investigations, but it does not cover the whole ground, seeing that his description of the operations ceases with the production of the first lot of concentrate, and does not describe the roasting and subsequent second set of concentration operations. The plant erected under the advice of Messrs. Brown and Madge included Hardinge mills, Richards-Janney classifiers, Callow dewaterers, and Deister tables. Readers of Mr. Nichols' paper wondered why treatment on Frue vanners is included in the scheme. It must be explained that a large amount of plant was already on the spot when the engineers took charge, and that the directors desired that use should be made of it. Mr. Madge, at the meeting, stated that these limitations interfered with his plan of crushing and concentration, and that the plant as at work did not meet his ideal by any means. It is notable that Mr. Nichols gives an assay of every product and accounts for all the ore and all the cassiterite contained in it, a proceeding rarely, if ever, adopted in Cornwall.

The tonnage was 100 tons of ore per day. Three Holman air-cushion stamps were kept working at 142 drops per minute, crushing through No. 32 Cornish mesh (diameter of aperture 0.053 in.) perforated screens. The pulp, after passing an automatic sampler, was lifted by the first bucket-elevator, traveling 283 ft. per minute, and passed to the Richards-Janney classifier, in which the first spigot gave 300 discharges per hour, the second 225, and the third 150. The first spigot discharge passed through a small dewatering tank to the Hardinge tube-mill and thence back to the elevator. The second spigot-discharge was the feed to the first row of three vanners, which were speeded to about 3 ft. belt-travel per minute and dropped 5¼ in. at the tail end. The third spigot-discharge was the feed to the second row of Frue vanners, speeded to about 2½ ft. per minute, with a 4½-in. drop,

and the overflow from the classifier passed to two small Callow tanks, from which the underflow formed the feed to the third row of Frue vanners, which were run as nearly level as possible and speeded to pull a not too clean concentrate in order to get a tailing lean enough to run to waste. The overflow from these Callows passed to three 8-ft. Callows. The tailing from the first two rows of vanners was reground in the grinding-pans, and with the slime vanner-tailing (third row) was elevated, passing to the two-compartment Richards-Janney classifier, from which the two spigot-discharges respectively fed the two Deister sand-tables; producing a concentrate only, and a tailing run to waste, while the overflow also passed to the 8-ft. Callows. The underflow from the Callows fed four Deister slime-tables. The overflow passed to two more pyramidal thickeners, the underflow feeding the fifth slime-table and the overflow going to waste. The five slime-tables produced a concentrate, and a tailing which was run to waste. The middling all passed to a dipper-wheel which elevated it to two small thickeners in parallel, the overflow from which passed to a larger pyramidal thickener. The underflow from this dewaterer was returned to the dipper-wheel, and the thickened middling

STAMPS AT GRENVILLE, CORNWALL.

was fed to a sixth slimer, the middling of which was close-circuited by passing back to the dipper-wheel. Thus the slime-tables ultimately produced only a concentrate, which was sent to the calciner.

Out of the 100 tons of ore treated per day, the concentrate weighed 2.631 tons, averaging 48% black tin or 32% metallic tin. The tailing contained 7.7 lb. black tin. The percentage of recovery was 78.6%. In order to get a higher-grade product suitable for the smelters, roasting and reconcentrating would be necessary, and the percentage of recovery as quoted by Mr. Nichols would be reduced by losses in these further operations.

One of the points raised in the discussion was in connection with the initial fine crushing, and some speakers argued that a coarser first product should be obtained. Mr. Madge, however, said that the grains of cassiterite are so small as to require this fine grinding, and that it was necessary even to regrind the first spigot discharge of the classifier. The question was also asked why this reground product was returned to the same classifier, to which Mr. Madge said that it was necessary to have the particles fine enough to pass over to the second compartment, and there was no special reason why a separate classifier should be used. I ought to add that Mr. Nichols did not act without the consent of the board, as Mr. Brown, the technical director, who had the whole matter in hand, gave this consent, considering that the figures ought to be publicly put on record.

As to the Carn Brea & Tincroft, incidents in connection with which I mentioned two months ago, I have now to record that the Carn Brea section is to be closed and efforts are to be concentrated on the North Tincroft, which is the most promising at present. E. S. King has not been able to find profitable ore, and the Company is short of money for development and mining. Before proceeding

further with the new mill provided by Lord Clifden, it was felt that independent advice should be obtained, and consequently W. H. Trewartha-James was asked to make a thorough underground examination. His report is not yet published, but his view is indicated by the decision as recorded above. The Botallack, after years of struggle and after the repeated provision of new capital, is on its last legs, and stoppage may be announced at any time. Wheal Jane, belonging to the Falmouth Consolidated, under the control of the Schiff group, after going into the hands of a receiver three months ago, was shut down this week. The Dolcoath returns of concentrate have recently been showing ominous drops, and unless the side lodes recently cut prove to be valuable, shareholders will have some anxious moments before long.

NEW YORK

COLOMBIAN MINING CONCESSIONS.—ESPERANZA AND SANTA GERTRUDIS.—DIVIDENDS.

There has been much interest lately in foreign companies, and the Pearson contracts in Colombia have come in for a good deal of discussion. The quietness to the reports of international politics being a large factor in this matter was given by Francisco Escobar, the Colombian consul in New York, who has made an official statement that the canceling of the concessions resulted simply from popular opposition in Colombia. The Pearson interests had denounced many thousand acres in the ordinary way, but when the title was about to be confirmed, following the usual procedure, great opposition developed in the national legislation of Colombia on the ground that it was dangerous to the best interests of that republic to have so large a part of its area in the hands of a single foreign financial group. Under the circumstances there was nothing else for the Pearsons to do but withdraw. While speaking of Colombia, it may be noted that the Colombian venture of the Oroville Dredging Co. has also evoked much recent comment. The announcement that a dividend would be paid in January and that recent returns would have averaged 65c. per yard, rising for one week to \$1.23 per yard, has been given full publicity, but has been met by the rejoinder that the payment of a dividend at this time is only possible through deferring the repayment of the \$228,000 advanced for the development of the property, and that even if the present unexpectedly high profits are maintained it will be more than a year before the Company will repay its cash advances, not to mention the note issue held by the Oroville Dredging Company. It is also remarked that since present returns are much higher than expected, subsequent ones may be lower than expected and the present jubilation bears the aspect of whistling before getting out of the woods. It is reported, by the way, that important New York interests are considering taking over a large area of alluvial ground south of Pato, and some interesting announcements may be made later.

The report of the Esperanza for the quarter ended on October 1 has been given out, and shows that the mill crushed 23,355 tons of ore, and treated 34,417 tons of tailing at an estimated profit of £21,819. Godfrey Doveton has made a report, and it is stated that, as a result of his work, a better recovery on the refractory San Carlos ore will be made. There was no interruption of freight service between the mine and the smelter of any importance, but the congested condition of freight at the ports of entry remains unrelieved. This makes slow delivery of all freight, and has caused some delays in the installation of equipment on the upper levels of the mine by the non-arrival of necessary parts of equipment. The management hopes that operations at the end of the year will not show much loss, in spite of the disturbed conditions. At the Santa Gertrudis, the mill crushed 87,137 tons during the quarter, and the receipts from bullion were \$700,000, corresponding to an operation profit of \$295,000. The profits show an increase since working costs were reduced and the tonnage handled increased. The labor supply at the mine is excellent.

Some of the mining companies are prospering even though general business is slack. Phelps, Dodge & Co.

has declared an extra dividend of \$2.50 per share, coincidentally with making a larger output of copper than in any preceding year, and the Hedley Gold Mining Co. has declared an extra dividend of 12% in addition to its regular dividend of 3%. The mathematicians of the share market have computed that the Anaconda Copper Mining Co. will earn its regular rate of dividends this year in spite of the lower average price at which its copper has been sold. The Anaconda production for the year is estimated at 270,000,000 lb. of copper. The keen interest in Anaconda is due to the fact that it is the 'milk cow' for the Amalgamated, which is one of the favorite speculative issues in the share market. The Amalgamated has large holdings in other companies, but only derives about \$300,000 per year from its International Smelting & Refining stock, and still less from its other holdings.

Amalgamated Copper has \$12,527,000 notes outstanding, and its accounts payable aggregate \$7,737,000, a total of \$20,264,000. Against this, according to the report of 1912, there was due for copper delivered \$3,757,000; due from smelting and mining companies, \$8,440,000; and \$1,182,000 cash, a total of \$13,380,000.

BUTTE, MONTANA

OPERATIONS AT THE DAVIS-DALY, WEST STEWART, BUTTE & LONDON, AND TROPIC MINES.—ORE-BINS AT ANACONDA.—TAXING MINERAL LANDS.—ANACONDA AND BAILLAKLAVA SUIT.

The Davis-Daly Copper Co. is now shipping nearly 300 tons of ore per day to the smelters, this being mined from all points between the 1200 and 1900-ft. levels.

The scale of operation at the mines of the Anaconda company can be realized when it is stated that the capacity of the mine ore-bins is now 50,000 tons. The bins were recently enlarged to this total capacity to prevent a shut-down in the cold weather, when the smelters have trouble handling the daily production. With the increased bin capacity, most of the mines could run several days without depending on the smelters to keep the bins empty.

The West Stewart mine will be closed for a period of three months pending repairs in shaft, machinery, ore-bins, etc. The Butte & London property is being equipped with a 425-hp. electric hoist, with which the shaft will be deepened from the 100 to the 1600-ft. levels.

The Supreme Court of Montana has rendered a decision to the effect that the mineral reservations made in deeds for land from the Northern Pacific railway are taxable. This is an important decision, and will affect the mining industry in Montana in several ways. For one thing, if the decision is upheld, the railroad company will not be so prone to make indiscriminate blanket reservations in its deeds if it is to be taxed accordingly. As things stand today, a purchaser of a provisional title to Northern Pacific lands is not eager to prospect any mineral showings on his land, as the railway company might step in and lay claim to it.

The Tropic shaft of the Anaconda company is now down to the 700-ft. level, where good oxidized copper ores have been opened. The Tropic lies east of Silver Bow creek, near the property of the East Butte Copper Mining Co. Favorable development at the Tropic will be encouraging to neighboring properties. The deep oxidized zone in the Tropic is characteristic of all veins on the flat west of the Continental fault, although water-level is not as deep as in the mines on the hill.

Butte capital is heavily interested in the Rocher de Boule Copper Mining Co. in the Hazleton district, British Columbia. A heavy outlay has been necessary to place the property on a profitable basis. A gravity aerial tramway over 3 miles long is to be erected, and a hydro-electric plant to furnish power to the mine has been installed. The operators are very sanguine about the mine, as several veins have been developed, one of which is 9 ft. wide and contains over 12% copper.

The amicable adjustment of the litigation between the Anaconda Copper Mining Co. and Butte-Baillaklava Copper Co. meets with general approval at Butte. Some would

argue that mining litigation lends life and activity to a camp, but the saner heads realize that the conditions are artificial and do not make for permanent prosperity. It would seem that the Ballaklava company obtained an entirely fair division of the veins, and should now be able to proceed with mining and development in a profitable way. The settlement of the litigation is apparently accompanied by good feeling all around. The president of the Ballaklava, in a public letter, commends the fairness and just dealing of the Anaconda company in the matter.

PLATTEVILLE, WISCONSIN

CONDITIONS IN THE ZINC-LEAD DISTRICTS.—DETAILS OF MINING WORK.—ORE PRODUCTION AND PRICES FOR NOVEMBER.

The month of November was featured by bad weather, consequent bad roads, and declining zinc-ore markets in the Wisconsin zinc-lead mining districts, but all this failed to deter producers from maintaining a fairly normal production and making further provision for still greater development of the field. From the Missouri districts came reports of reduction in wages of miners, but no such calamity visited the miners of Wisconsin. On the contrary, miners were in strong demand at several points in

ments were made as follows: Linden Separating Co., 347,970 lb.; National Separating Co., Cuba, 629,640 lb.; Wilkinson mine, 3,277,600, all going to the Grasselli Chemical Co., East Chicago, Indiana.

Shipments by districts were made as shown in the following table:

District.	Zinc, pounds.	Lead, pounds.	Sulphur, pounds.
Benton	3,846,000	116,500	3,277,600
Hazel Green	2,580,000	118,800
Livingston	2,500,000
Platteville	1,920,000	50,000
Linden	1,836,000	147,640	347,970
Cuba	1,834,000	629,640
Highland	1,356,000
Harker	618,000
Shullsburg	424,000	66,000
Mineral Point	246,000	59,200
Montfort	242,000
Rewey	84,000
Mineral Point Zinc Co....	2,647,500
Total	20,133,500	558,140	4,255,210

The following mines contributed to the output for the

EMPIRE MILL AND WORKS OF MINERAL POINT ZINC COMPANY.

the field, at wages maintained through the greatest period of prosperity.

Prices for zinc ore averaged well during the month, 60% ore running through the month from \$39 to \$42 per ton. The low level for the field is graded at 30% zinc, which brought \$14 to \$15; 35%, \$16 to \$18; 40%, \$20 to \$22; 45%, \$24 to \$26; 50%, \$28 to \$30; and 55%, \$32 to \$34 per ton. A considerable gain was shown in the volume of high-grade ore from the field.

Out of a total shipment of 270 cars of zinc ore, both refined ore and crude concentrate, the Mineral Point Zinc Co. secured over half, or 5740 tons; Grasselli Chemical Co., 1529 tons; National Separating Co., 869 tons; Illinois Zinc Co., 689 tons; M. & H. Zinc Co., 386 tons; Empire Roasters, Platteville, 561 tons; and the Linden Separating Co., 240 tons. The last-named plant was shut down for a time, owing to shortage in the power furnished by the Mineral Point Public Service Co., which supplies the Linden district. The gross production of raw concentrate for November, from mines, aggregated 17,816,740 lb., and net refined ores and raw concentrate to smelters 12,603,630 lb. The Mineral Point Zinc Co. shipped 35 cars or 2,647,500 lb. of roasted ore to the smelter at De Pue, Illinois. Shipment of lead ore was comparatively light, the ore coming in quantity as follows: Saxe-Pollard mine, Linden, 147,640 lb.; Tripoli, at Mineral Point, 59,200 lb.; Fox, at Benton, 60,000 lb.; Wilkinson mine, 56,500; Vinegar Hill, Galena, 58,800; Beloit-Elmo, at Big Patch, 50,000 lb.; Kennedy, at Hazel Green, 60,000 lb.; and Winskill, Shullsburg, 66,000 lb.; a total of 558,140 lb. No appreciable gains were shown in the production of iron pyrite, the Wilkinson mine at Benton producing about 400 tons per week. Ship-

month: New Jersey Zinc Co., Gunn & Co., Highland; Glanville, Ross, Optimo, Hinkle, and Saxe-Pollard, Linden; Grunow, Peacock, Peni, B. M. & B., and Lucky Six, Harker; Barreltown for Mineral Point; O. P. David and Montfort; Coker, Ellsworth, and Rundell for Livingston; Peni for Rewey; Empire, Enterprise, East End for Platteville; Burr, Masbruch, and National Separating Co. for Cuba; Fontler, Fox, Crawhall, Indian Mound, Wilkinson, Temple & Lawyer, and Martin for Benton; Kennedy and Cleveland for Hazel Green; Milwaukee-Shullsburg and Winskill for Shullsburg; Black-Jack, Pittsburgh, Vinegar Hill Northwestern, Federal, and Wilson for Galena.

A number of new properties were opened for the first time to production at several points in the field which are destined to develop into consistent zinc-ore producers. The Highland district, out of the list for the greater part of this year, is now shipping one or two cars per day and will make one of the best showings of any district in the field before the winter is over. The shipments shown for Harker and Livingston cover ores produced in the Mifflin district.

A brief summary of the more important happenings in the field for the month may be stated as follows: The New Jersey Zinc Co. began production at Highland after a considerable outlay of money, and was in the market for men. A pump shaft is being sunk costing \$10,000. Engineers for the Company made tentative plans for mining by open-cut on the Carey land, removing the ore with steam-shovels. At Linden, the Saxe-Pollard Milwaukee combination bought the Hinkle property, shut it down for the present, and removed the working force of 30 men to the Saxe-Pollard mine, where large ore deposits are being

opened. The Glanville mine, with plenty of ore, is not up to standard conditions owing to mismanagement. The B. M. & B. Co., operating the Squirrel mine at Mifflin, resumed operations after a long period of idleness, and required more help. The Beloit Elmo, after two years, succeeded in getting into producing shape under the management of R. Davis, of the Wisconsin State Mining School. The old Enterprise mine at Platteville was again invaded, and drills are proving adjoining leaseholds recently secured. In two years this mine paid \$180,000 in dividends. Good developments in zinc ore were made in a drift in the West Hill Mining Co.'s leasehold, on the Stevens farm, one mile west of Platteville. The Cook mine at Cuba was taken over by local people, after three years' idleness, and a force of men started to work. The Roosevelt mine, another producer, passed into the control of Chicago capitalists and men were set to work. At Benton, the Frontier mine, which in five years has paid \$200,000 in dividends, and reported to be looking poor, opened new lodes, insuring an extension of life. Longhenry brothers, after much difficulty, opened ore and began production. The Martin mine, owned by the Vinegar Hill Zinc Co., began operations with a new plant and was producing 20 tons of ore per day at the close of the month. The Bull Moose mine reached ore in new ground and was rushing a new 100-ton plant to completion. The Sans Souci Mining Co., a new venture, was engaged in putting up a new power and milling plant. Good developments in ore were made in four new prospects. The finest discovery of zinc ore made in the field in years, if not in its entire history, fell to the lot of Homer S. Snow, of Platteville. This was at the Champion lease near Benton. The land was purchased outright for \$40,000. In scores of borings, made with two Keystone drills, not a blank was drawn. The lode has been proved east and west for 1000 feet. The elevations show ore in some of the borings at 95 and in others strongly mineralized territory extending to a depth of 140 ft. The width has not been fully determined to date, and the work of proving continues. The Cleveland Mining Co., at Hazel Green, is finishing a 100-ton power-plant on the Lawrence property, and another 150-ton plant has been started on the Scrabble Creek near by. The Pittsburgh Lead & Zinc Co., operating at Pilot Knob south of Galena, is constructing a new power and concentrating plant. New shafts are being sunk on extensions of the Winskill property at Shullsburg. The Wilson mine at Postosi was down for a time, due to shortage of coal which caught many mines unprovided. Bad roads prevented most of the outlying mines, many of which are heavy producers, from carting ore to railways most of the month. Leading mine managers interviewed on the condition of the markets expressed the belief that no changes will be shown for sixty or ninety days. Regardless of drawbacks, all thought it the best policy to continue operations, retaining plant equipment at maximum efficiency and holding working forces intact. When the figures showing production for the year are to hand, it will be found that the Wisconsin field has made its best showing in years, and fully 125,000 tons of zinc ore was sent to market.

TORONTO, CANADA

PROVINCIAL MINERAL RETURNS.—POSSIBILITIES OF NORTHERN ONTARIO.—GOLD DISCOVERY IN NOVA SCOTIA.

The Mines Department of Ontario has just published figures covering the mineral output, so far as obtainable, for the first nine months of 1913. These are as follows:

	Quantity.	Value.	Increase.
Gold, ounces	159,962	\$3,281,077	\$2,163,692
Silver, ounces	23,171,536	12,967,138	259,312
Copper, tons	9,237	1,311,681	169,605
Nickel, tons	18,233	3,825,000	405,196

Nearly all the gold came from the Porcupine district, chiefly from the Hollinger and Dome, also some from the Porcupine Crown and McIntyre mines, the total being worth \$3,106,250. The other gold mines making up the nine months' yield of \$3,281,077 were in the Long Lake, Swastika, Kirkland Lake, Larder Lake, and Sturgeon Lake districts. There were 31 producing silver mines: 27 in Cobalt, 2 in

Gowganda, and 1 in South Lorrain. In output the Nipissing led with 4,387,765 oz., then Coniagas with 2,662,687 oz., and La Rose with 1,903,345 oz. There were a number of other good producing mines. Cobalt is developing splendidly and fulfills the prophecies of the most sanguine; but Porcupine is beating all estimates, and perhaps people will now believe that there is gold in Ontario that only requires men, money, and faith to develop it into good paying gold camps, such as the Larder Lake, Swastika, Long Lake, Kirkland Lake, and Sturgeon Lake districts.

A rich gold discovery has been made quite recently at Isaac's Harbour, Guysborough county, Nova Scotia. The vein was opened by a Mr. Gisburne about forty years ago with good results, when a fault came in, and the search for the vein made at different times since, has been rewarded, a Mr. Keuh having succeeded in finding it. This achievement, after forty years' intermittent labor by various parties, has created considerable interest in Nova Scotia gold mining.

At a special general meeting of the Jupiter Mining Co., the directors were authorized to raise \$40,000 by the issue of \$50,000 6% one-year bonds, which are to be offered to the shareholders at 80, and any balance that may not be taken up will be offered to the public. The indebtedness of the Company amounts to \$36,402, of which \$14,000 is due on machinery and power equipment ordered for the mill.

JOHANNESBURG, TRANSVAAL

SHORTAGE OF NATIVE LABOR.—GOLD OUTPUT.

The principal mining topic of interest on the Rand is the increasing scarcity of unskilled native labor, and when the figures are carefully examined, some surprise is expressed that with the growing scarcity the output of gold is not further restricted. At this time of the year the supply generally begins to right itself, but during the latter half of 1913 the loss of labor has been so abnormally large that the year is bound to finish with a smaller available supply than for several years past. Prior to July, the month of strike disturbances, native laborers were deserting the Rand gold mines in extra large numbers. In June, for instance, there was a leakage of 9550 natives, but in July this increased to 17,852, and in August to 12,019. The loss in September came down to 5586, and in October to 3755, and it may disappear by the end of the year; but already there has been a loss of over 50,000 as compared with January, while the previous year showed a gain of approximately 7000. The deep-level mines have been by far the greatest sufferers. One has already been compelled to close down altogether through an inadequate supply of native labor, and several of the largest mines report large losses. Up to May last the Witwatersrand gold mines were showing the usual progressive increase in the output of gold, but it is doubtful whether the setback then suffered will be made up in the coming six months. Under these circumstances, and in the face of the fact that October showed a net loss of 3755 laborers compared with September, it is satisfactory to notice that the Rand gold output for October showed an increase of 11,104 oz. over that of September, although when compared with August a slight decline is noticeable. The Rand output as declared by the Chamber of Mines for October gave a total of 687,515 oz., valued at £2,920,379. As compared with September, there was a decline of no less than 170 in the number of stamps dropping, of which, however, no less than 120 may be attributed to the closing of the Jupiter, the deepest mine on the Rand. Even the Randfontein Central had 25 less stamps dropping, the scarcity of labor being also intensely felt at the Crown Mines. It is quite an unusual monthly occurrence for none of the Rand gold mines to drop additional stamps, but this happened in October and may be regarded as positive proof that native labor is universally scarce throughout the district.

The position of affairs at the East Rand Proprietary mines continues to be interesting, and the announcement that the renewal of Ross Skinner's engagement will not take place, has not caused much surprise. Since June the

estimated monthly profits have declined over £10,000, due, it is explained, to a smaller tonnage being milled owing to the acute shortage of labor caused by the recent industrial disturbances. The quarterly report for the three months ended September 30 states that development covered during that period 11,808 ft., of which 9326 ft. was sampled, giving an average reef width of 25 in., and over that width an average assay-value of 9.9 dwt. per ton. The closing down of the Angelo Deep and Hercules stopes has naturally thrown the development into the profitable areas in the northern part of the mine, hence the satisfactory results obtained during the quarter; and the further development, about to be undertaken beyond the water dike, will be watched with considerable interest. It is generally known that the Angelo Deep and Hercules, east of the water dike, have proved unprofitable, and it seems likely that the large area owned by the Company on the dip of this vein, and east of the water dike, will also prove of little value. It naturally follows that the future of this great property may have to depend upon the results obtained beyond the water dike, as the underground pumps and dams, to allow the water dike to be pierced, have been installed and completed. Future development operations beyond the water dike are regarded of the highest importance. The future is not, however, by any means discouraging, for beyond this dike, at a depth of 4000 ft., profitable ore was long ago disclosed.

YERINGTON, NEVADA

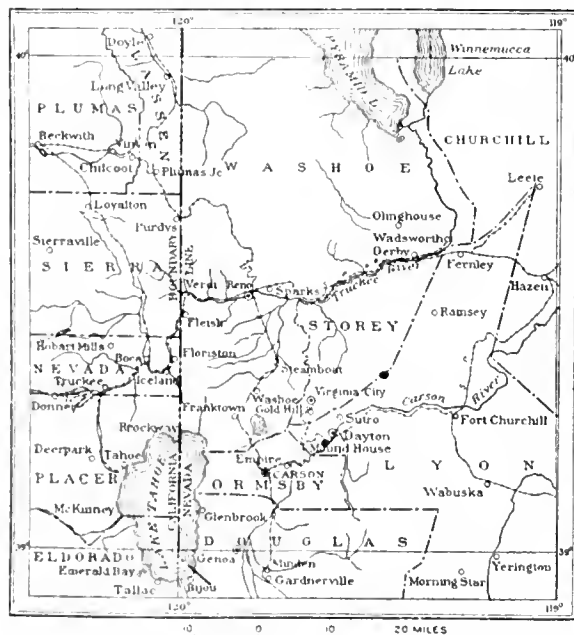

DEVELOPMENTS AT NEVADA-LUDWIG.—PLANS FOR A LEACHING PLANT.—GOLDEN GATE MINE.—SILVERADO UNDER LEASE AND BOND.—OPERATIONS AT PINEGROVE.

The new orebody discovered about three months ago in the Casting Copper group of the Nevada-Douglas properties, promises to be the most important find ever made in the property. This group is about one-half mile south of the Douglas mine in territory to which little attention was paid in the past. There is an old shaft 300 ft. deep, and on the 100-ft. level some driving was done and an unknown amount of low-grade ore partly developed. About three months ago a little more work was done with the idea of testing some of this ore by leaching, and by accident the new orebody was broken into. At the present time an orebody about 250 ft. long, 50 ft. wide and 170 ft. deep is developed, although the limits have not been found below the 200-ft. level. About two cars per day of 8% ore is being sent to the smelter. This all comes from development work. The ore occurs in a garnetized zone near a contact of lime and shale, and the prospects of opening large quantities are considered very good, as there is much unexplored territory in this group. On the 800-ft. level of the Ludwig mine a body yielding about 6% ore is being explored. It contains large pieces of native copper and these are being sorted out and will be shipped separately. The Company plans to erect a leaching plant at Ludwig. The Greenawalt process will be used, and results of tests, using sulphuric acid as a solvent, have been very encouraging. By agitation 95% extraction has been obtained in a few hours. Precipitation will be by electricity. The ore will be ground to 30-mesh, and the tests at the Company's Denver plant have indicated that the mechanical difficulties can be easily overcome. Sulphuric acid will be made on the ground, using low-grade chalcopryite ores developed on the 750-ft. level of the Ludwig.

Development work is under way on lower levels of the Golden Gate mine, but the orebodies found in the upper workings have not yet been cut. The mine is in Little Antelope valley, Mono county, California. The ore occurs in a fissure in gneiss. It is opened to a depth of 300 ft. and practically all of the ore above this level has been taken out by lessees. The last lessees built a 10-stamp mill, run by water power, and milled about \$35,000 worth of ore which yielded \$4.91 on the plates. Concentration was not attempted. It is said that the extraction is low. The property is said to have considerable merit, but needs development at depth. The ore-shoots on the surface are short, but increase in length as depth is obtained. The

old Silverado is under lease and bond to local men. It is near Masonic, California. It also is a narrow fissure, and ore is said to average 10 to 24 inches in width, with a value of \$25 per ton. There is an old mill on the property, but the present owners expect to ship ore to the smelter at Thompson and will sort out the high-grade ore for this purpose.

The old Wilson mine at Pinegrove is again being operated. It is about 25 miles south of Yerington. Electric power is obtained from the Truckee River General Electric Co., and without this power it would be impossible to operate at a profit. The Wilson mine is one of the old gold mines of the state and is stated to have produced about \$4,000,000, mostly by lessees. About five years ago the mill was destroyed by fire, and shortly after that the present owners acquired the property. A long adit was driven in from Scott's cañon side for the pur-

PART OF NEVADA.

pose of cutting the ore about 500 ft. deeper than the present workings, but after driving this in over 4000 ft., work was stopped and the Company proceeded to clean out the workings on the Pinegrove side of the range. It was found that the adit had lowered the water-level several hundred feet and made available a large amount of valuable stoping ground which the former owners had been unable to mine on account of water troubles. The ore occurs in a series of parallel lenses or shoots along fracture zones in grano-diorite. A large rhyolite dike is believed to have made conditions favorable for mineralization. At the old Rockland mine, east of Pinegrove, the ore is found along the contact of a rhyolite dike and grano-diorite. This is the same belt as is found at Pinegrove. The Pinegrove Gold Mining Co. erected a 10-stamp mill with 1050-lb. stamps. After passing through the breaker the ore goes to a grizzly. The oversize from this goes to the battery, and the undersize directly to two 6-ft. Huntington mills, where the pulp from the batteries is also ground finer. Grinding is done to 40 mesh, and after passing over four amalgamating plates the tailing from plates is treated on Send and Deister tables. The concentrate will assay about \$80 and is being stored for the present. A compressor plant has also been erected, and, with the exception of some of the motors, the entire plant has given satisfaction. The reopening of this old camp, where ore was first discovered about 1864, has stimulated interest in the entire district, and considerable prospecting is being done.

The tonnage of ore received at the Mason Valley smelter for the week ended December 4 is as follows: Mason Valley, 2996; Nevada Douglas, 1086; and other mines, 488 tons; a total of 3670 tons. Three cars of matte was shipped during the week.

General Mining News

ARIZONA

GILA COUNTY

(Special Correspondence.)—During November the Inspiration Consolidated company made a total advance in its underground workings of 3300 ft., of which 1136 ft. was in large drifts, 782 ft. in smaller drifts, and 1332 ft. in raises. Nearly all of the raises were driven in the Colorado orebody, only two being driven in the Joe Bush portion for the purpose of affording channels of ore extraction from the overlying dumps or stockpiles. One of these two raises holed through into the edge of a stockpile. At the mill the usual activity in construction is shown in all divisions. Three No. 8 Allis-Chalmers gyratory crushers have been unloaded. The coarse-crushing plant will consist of four machines. The shaft of the Arizona Commercial is down 1350 feet.

Miami, December 12.

Messrs. Locke and Bateman have recently made a geological examination of the Inspiration mine, so that they may make a more extensive study and for the purpose of secondary enrichment investigation. This is being conducted under the direction of L. C. Graton, of Cambridge, Massachusetts, who has prevailed upon various other mining companies to bear the expense of a detailed investigation of the copper deposits in the various parts of the country. Last week, the east drift on the 650-ft. level of the Iron Cap was connected with the Eureka shaft of the Arizona Commercial, thus improving ventilation and affording another exit for miners. The new surface equipment at the Old Dominion is being installed as fast as possible. A Hardinge mill was erected in the old concentrating plant, and should soon be at work. An Aldrich quintuplex electric pump has been ordered for the 1800-ft. level of the mine. This will raise water to 1200 ft., and from there other pumps will raise it to the surface. A winze is to be sunk from 1600 to 1800 ft. on the west side. Three furnaces are in blast. The Calumet & Arizona Copper Co. has been criticized at times for not paying more dividends and acquiring too much property.

The Inspiration Consolidated Copper Co. at Miami, will add to its equipment six motors ranging from 50 to 100 hp., and control panels.

MOHAVE COUNTY

On the 100-ft. level of the Gold Reed Mining Co.'s Mayflower claim, 4 ft. of \$30 to \$80 gold ore has been opened for 15 ft. The Company is also sinking in the Jupiter claim, adjoining the Tom Reed.

GREENLEE COUNTY

On December 9 eleven kegs of powder exploded prematurely in an open-cut of the Arizona Copper Co.'s mine, killing four Mexicans and injuring three other foreigners. A large Dorr thickener is being built at the Company's plant.

YAVAPAI COUNTY

The Humboldt smelter will probably resume the treatment of custom ores. At present nearly all ores from the county are sent to Douglas. New machinery is being installed at the smelter, which is producing matte from ores of the Bluebell mine. Rich gold-silver ore has been shipped from the Shamrock on the Hassayampa. The United Verde Copper Co. has paid to the county treasurer a check for \$148,768, being taxes for the year. At the Little Daisy mine, near Jerome, the Douglas shaft is down 800 ft., with further sinking to be done directly. On the 1230-ft. level of the Haynes, a 24 by 30-ft. station has been cut, and an electric pump and compressor are to be installed.

A large tonnage of ore has been developed by the Nelson Mining Co., at Crown King, and a narrow-gage railway will be constructed to connect with the Bradshaw mountain line, a spur of the Santa Fe system, while a 20-stamp mill will also be built near the mine.

CALIFORNIA

AMADOR COUNTY

The South Eureka Mining Co., Sutter Creek, will place in operation in its mines a 2½-ton electric storage-battery mine locomotive, recently ordered from the General Electric Company.

CALAVERAS COUNTY

Further complaints of damage by smelter fume from the Penn Mining Co.'s smelter near Campo Seco have been made by farmers to the authorities at Sacramento. Nearly 90% of the year the prevailing wind carries the fume away from the farming lands of the county, and almost right at the smelter excellent fruit and crops are grown. As a matter of fact, along the Mokelumne river there are several large orchards, vineyards, and other fields which have every appearance of being in the best of condition. Oaks and pine trees, the latter being the first to suffer from fume, are growing in large numbers just across the river from the smelter, and have not suffered. The Company has spent a large sum of money in testing the 'Thiogen' process for minimizing the fume produced in smelting.

LOS ANGELES COUNTY

The Chamber of Mines and Oil, the Sierra Madre Club, and the southern California sections of the American Chemical Society and of the American Institute of Mining Engineers, had an informal dinner on December 16 in honor of Irving C. Allen, petroleum chemist of the U. S. Bureau of Mines, and Charles E. van Barneveld, director of the Department of Mines and Metallurgy, Panama-Pacific International Exposition. Mr. Allen spoke on government plans regarding the petroleum exhibit at the exposition in 1915. Mr. van Barneveld discussed a state-wide movement for petroleum exploitation at the exposition. Norman Bridge responded on behalf of the oil men of California. S. E. Vermilyea, president of the Chamber of Mines and Oil, presided. The members of the club, the Chamber, and the Institute have been invited to participate with the members of the American Chemical Society in an informal dinner at the Hollenbeck hotel, December 19. The following program will be presented: 'The Technological and Coöperative Petroleum Work of the Bureau of Mines,' by Irving C. Allen; and 'Antimony, Its Ores, Metallurgy, and Uses,' by L. C. Mott.

MODOC COUNTY

News of discovery of ore near Willow Ranch has reached Fort Bidwell. The miners have 8 ft. of \$15 ore, and men in the High Grade district are interested.

NEVADA COUNTY

The machine-drill testing apparatus, the invention of W. D. Paynter of Grass Valley, and described in this journal of August 2, 1913, has been placed on the market. One machine has been sent to the Copper Queen mine, Arizona, and another is being made for the Goldfield Consolidated, Nevada.

PLACER COUNTY

A good asbestos deposit has been discovered by A. W. Hulbert in the Rock Creek district. The Guggenheim company is prospecting placer ground near its main area on the American river, 7 miles from Auburn. Options have been extended on some ground bonded last spring.

SHASTA COUNTY

(Special Correspondence.)—The steel flue of the Field process plant, at Redding, has been practically completed, and the first test of the process will be made about December 15 unless inclement weather interferes with remaining construction work. The flue is 300 ft. long, with the upper half equipped with jackets for the passage of cold air, and the lower part containing 36 hoppers. It is planned to treat sulphurous fumes by means of cold air, ammonia being the refrigerating agent. A consignment of ore from the Balaklala mine is on the ground for the initial test. The Mammoth Copper Mining Co. is building a new road to the recently purchased Spread Eagle group and will probably commence shipments to the Kennett smelter in the early spring. The Shasta-Belmont Mining

Co. has let a contract for the building of a road from its mines to Heroult, and plans early shipment of ore to the Kennett smelter. The ore carries high copper content, also gold and silver. Carson City, Nevada, people are interested, and W. E. Casson is manager. In the Whiskeytown district, mining is distinctly on the up grade. At the Mad Ox, recently acquired by W. H. McEwen of Oakland, the lower drift is being extended to cut the vein which yielded well in former years. The property was at one time operated with excellent results by Messrs. Hearst and Haggin. The Black Hawk is yielding good ore and the mill is operating steadily. A 12-in. shoot of rich quartz has just been found in the West End, recently reopened by Eaton and Blair. Developments in the Gamberinus, Honey Bee, and other mines are reported as encouraging. L. B. Barnes is arranging for the operation of the Silver King mine on a larger scale. Some gray copper has been discovered in addition to silver-bearing ore. The Russell placer mines, near Igo, were lately inspected by San Francisco investors. A dry-land dredge

property averaging about \$40 per ton. Work has been resumed in the west drift on the Magenta-Turner vein through the Prudential adit. The Big Indian Mining Co. has been developing its property on Leavenworth mountain for three years, and in a few days a drift is expected to cut the Big Indian vein.

EAGLE COUNTY

During the past week the Marion Henry Mining Co., operating the North Dakota group of claims at Brush creek, shipped to the Leadville smelter 40 tons of ore, the first shipment sent out from the property. The vein from which the ore comes is 5 ft. wide, and in this vein is a small streak, 18 in. wide, from which assays of from 600 to 900 oz. silver per ton have been obtained. In the Lady Belle, 60 ft. from its boundary, 2000-oz. ore had been opened. Lessees at the South Dakota cut ore assaying 20 oz. per ton.

LAKE COUNTY (LEADVILLE)

It is admitted that there would be greater mining activ-

SCENE IN THE HIGH SIERRAS.

is employed to excavate the gravel, and results are said to be satisfactory.

Redding, December 8.

Ten carloads of copper ore was shipped from the Bala-kala mine, on December 12, to Wabuska, Nevada, where it will be smelted in the plant of the Mason Valley Mines Co. The Noble Electric Steel Co.'s smelter, at Heroult, has resumed work after a shut-down since July 15. The furnaces have been altered to use coke instead of charcoal. The electrodes are of graphite, 12 in. diameter and 48 in. long. Eighty men are employed. At Kennett the Mammoth Copper Co. has just bonded 34 claims in the Spring Creek and Squaw Creek districts, from the Shasta Copper Exploration Co. The bonding agreement was filed for record on December 10.

The Mountain Copper Co. has developed a large tonnage of low-grade ore, and it has been announced that a large concentrating plant is to be built, the first unit to be complete at the end of 1914.

TUOLUMNE COUNTY

Electric motors are being installed throughout the equipment at the Eagle-Shawmut mine. Instead of hoisting ore to the top of the shaft, it is to be hauled to the adit-level and then trammed to the mill by an electric locomotive.

COLORADO

CLEAR CREEK COUNTY

The Dividend Mining Co. is developing the Annamosa claim at Empire, and has a shaft down 900 ft. On No. 4 level the ore has been opened for 60 ft., and is rich in gold and silver.

On No. 6 level of the Santiago mine rich copper pyrite has been opened. Regular shipments are made from this

ity at Leadville if the underground workings of Fryer hill were unwatered, but plans that were arranged during the past year have fallen through. A large number of companies were interested in the project, but failed to sign an agreement, to contribute to the cost, by October 1, the date set for all to come in. It is stated that the whole area could be drained and permanent pumps could be installed for about \$120,000. From the Big Four, Breece hill, there was recently shipped 47 sacks of ore valued at 100 oz. gold per ton. This came from No. 3 level, where it is found in pockets in a stope 40 ft. wide. In the Montezuma district the Cora Belle mine has been developed by six adits, No. 5 being in 1000 ft., and the others from 500 to 800 ft. The ore-shoots vary from 2 to 10 ft. wide, and shipments to the Leadville smelter average 26 oz. silver and 40% lead. Milling ore is sent to the Sutton-Steele company at Denver. On Glacier mountain, the McCulloch main adit is in 1300 ft. and six veins yield silver-lead ore similar to the Cora Belle.

PARK COUNTY

According to the State Commissioner of Mines, T. R. Henahan, there has been a revival in mining at Alma. The following are the properties that are now shipping and have a regular payroll: No End, the heaviest shipper in the district at the present, is yielding a fair grade of ore; Morning Star, which has a new mill and is getting returns; Hock Hocking is shipping and developing; Magnolia, shipping; Galveston, developing; Webber group, developing; Good Samaritan, shipping; and East London, developing.

TELLER COUNTY (CRIPPLE CREEK)

A great deal of damage was done to the district by the recent snowstorm, by covering all railroads and trails

several feet deep, damage to transmission lines and telephones, blowing over smokestacks, and preventing ore shipments. The electric pumps on the 1600-ft. level of the Golden Cycle mine were 'drowned,' and the steam pumps are not used on account of shortage of fuel. The lower levels of this mine and the Vindicator will be flooded. Rescue work in the Golden Cycle has been prosecuted with great energy since the fall of rock, and the bodies of S. Sorensen, P. Kevany, and F. M. Woods have been recovered. Lessees at the Granite Consolidated, on Battle mountain, have opened rich ore. The Portland Gold Mining Co. will pay an extra dividend of 2 cents per share, amounting to \$60,000. The total for 1913 is \$300,000, and \$9,457,080 to date.

THE SAN JUAN

In the Mountain Top, at Ouray, No. 3 vein shows 12 in. of rich ore. The north drift is in 600 ft. A new shoot of ore is developing well, and 39 in. assays \$32 in silver and 17% lead. The Brown Mountain smelter is working satisfactorily.

IDAHO

BLAINE COUNTY

Twenty-two inches of galena has been opened in the Queen of the Hills mine. The development is in the adit, 500 ft. below the apex of the vein. Charles Bonner is superintendent of the property, which is being worked under a bond and lease.

IDAHO COUNTY

(Special Correspondence.)—Spokane men have organized the Oro Grande Gold Mining Co., capitalized at \$1,500,000, to take over the old Hogan mine, mill, placer, and camp in the Oro Grande district of the central Idaho gold belt. By means of open-cuts, 100,000 tons of ore averaging \$3 to \$4 per ton in gold was mined years ago. The 20-stamp mill and cyanide plant is to be overhauled, and mining will be started during the winter. Andrew Prader is manager.

Spokane, December 12.

SHOSHONE COUNTY

Control of the Stanley mine, situated between the Hercules and Benton, has passed to outsiders, who secured 600,000 shares in the company from Herman J. Rossi and William Merks at 5 cents per share. The Green Mountain Mining Co. has been organized with a capital of 500,000 shares of 1 cent each, which are held by the Marsh Mining Co., the former being formed to work the Poorman Extension mine, adjoining the Marsh. Option payments on the Amazon-Manhattan group of eight claims, on Beaver creek have been made, leaving \$80,000 to be paid out of the total of \$160,000.

The preliminary settlement of the controversy between the Caledonia and Bunker Hill & Sullivan companies was ratified at Wallace on December 1, at a largely attended meeting of the stockholders of the Caledonia company. More than 1,064,000 shares of the capital stock voted in favor of the directors' agreement with the Bunker Hill company. The meeting was held to approve or reject the agreement entered into by the boards of directors of the two companies some time ago for dismissal of the Bunker Hill suit against the Caledonia, involving the apex rights to the orebodies existing in the Caledonia property now pending in the federal court. Under the settlement approved by the Caledonia stockholders, the Bunker Hill company receives approximately 1,300,000 shares of the Caledonia stock and representation on the board of directors. In return for this the present suit is to be dismissed and the Caledonia is given the right to connect its workings by an incline raise with the Kellogg tunnel of the Bunker Hill to facilitate handling its ores. It also agrees to tram such ores through the Kellogg tunnel to one unit of the Bunker Hill mill, on which a lease is also given. To provide for the stock which the Bunker Hill is to receive, the stockholders have ratified the increase of the capital stock of the Caledonia from 1,500,000 shares at \$1 each to 2,605,000 shares at \$1 each. A quantity of lead ore from a mine in Spain, owned by Dan Cordonier, formerly of Burke, has been received at the Hercules mill for testing purposes.

The Coenr d'Alene-Crescent Mining Co., capitalized at 1,250,000 shares of \$1 each, has been organized to develop the Evolution mine near Osburn, which has been recently worked by lessees.

MICHIGAN

HOUGHTON COUNTY

Three shifts are being worked underground in the Tri-mountain, and 60 drills are in operation. At La Salle the new electric pump has been installed at No. 2 shaft. An endless-rope haulage has been started on No. 42 level of the Osceola, its length being 2200 ft. No. 2 shaft of the Victoria is being sunk from No. 24 level. Three English miners were murdered in their beds at Painsdale on December 7, following Judge O'Brien suspending sentence in injunction cases. A large number of indignant citizens held a meeting and insisted on the courts and officers doing their duty. All companies declared a half holiday with full pay for December 10, when indignation meetings to rid the country of the agitators were held. The district was considerably excited.

MONTANA

BROADWATER COUNTY

(Special Correspondence.)—The Keating shaft is to be deepened from 800 to 1200 ft. The Congress group of claims, in the Radersburg district, has been equipped with a dry-concentrating mill. Work on the Black Friday mine is expected to be resumed in the near future.

Radersburg, December 12.

GRANT COUNTY

(Special Correspondence.)—A discovery of rich gold ore is reported from the Sunrise mine, 12 miles northwest of Phillipsburg. There is said to be two feet of ore assaying over \$2000 per ton.

Phillipsburg, December 12.

LEWIS AND CLARK COUNTY

An amalgamating and cyaniding mill to treat 50 tons of ore per day is to be erected by the Caroline Gold Mining & Milling Co., whose property is five miles south of Helena, near the head of Grizzly gulch. This will be the first unit, additions to be made later on. Underground work is done by two incline shafts, and a good tonnage of ore has been opened.

MADISON COUNTY

(Special Correspondence.)—It is said that the Watseka mine at Rochester is to be reopened. The McNunes of Salt Lake City have already spent a good deal of money on the property, but were driven out by water. It is thought that modern pumping methods may overcome this difficulty. The Pritchett property in Bear gulch is being operated by Bielenberg and Higgins. The ore contains gold, silver, lead, and copper.

Rochester, December 12.

SILVERBOW COUNTY

A safety device or controller, the invention of C. R. Welch, formerly of Butte, was tried on the Mountain View hoist at Butte recently, in the presence of the Anaconda company's officials and the state mine inspector. The gear prevents a hoist 'running away' or overwinding.

NEVADA

ESMERALDA COUNTY

A new pumping plant, with a capacity of 200,000 gal. per day, is being installed on the 500-ft. level of the Sandstorm-Kendall mine, where the flow of water is as high as 150,000 gal. at times. The pump will be fitted with three 6 by 10-in. plungers, and electrically driven.

NYE COUNTY

The Tonopah Extension Mining Co. has ordered a 150-hp. induction motor and starting panel from the General Electric Co. P. Zelavin, who was injured in the Belmont mine some time ago, has been awarded damages of \$6500 against the Company. The mines of the Tonopah district produced 11,406 tons of ore worth \$271,015 during the week ended December 13. Dealing with the recent developments in the Extension mine, the *Tonopah Miner* discusses the pos-

sibilities of the western ore zone of the district, and there are good prospects for the Victor, Cash Boy, Merger, and Midway mines.

STOREY COUNTY

When the water is lowered below the 2700-ft. level of the north end mines of the Comstock lode, it is thought that good ore will be opened, as reports of mining operations in 1880 to 1898 showed little prospecting had been done below 2500 ft. in the Mexican and Union Consolidated mines. The water is now 38 ft. below the 2500-ft. level, and another Starrett pump has been lowered into the winze.

NEW MEXICO

SOCORRO COUNTY

On December 1 the Ernestine Mining Co. started custom milling, being the third ore buyer now in the field. During November an average of 162 tons of ore was treated per day in the mill. Additional tanks are being added to the cyanide plant.

OREGON

BAKER COUNTY

At a depth of 160 ft. in the Imperial mine, ore assaying \$200 gold and 40 oz. silver per ton has been opened for 14 ft. Shipments are being made to a smelter.

COOS COUNTY

At the coal mine being developed by C. A. Smith and associates near Marshfield, the shaft is down 1200 ft. The equipment is to be operated by electric power.

UTAH

JUAB COUNTY

The new vein opened on the 600-ft. level of the Iron Blossom is showing better ore than when first cut. Development is still in progress on the 1900-ft. level, and although nothing of importance has been found there is a good showing there. It is probable that a dividend of \$50,000 will be paid for Christmas. At the Gemini, the main shaft is down 1650 ft., and a winze is down about 350 ft. below this. A flow of water comes in at 1700 ft., and from 1500 to 2000 tons of ore per month is mined from the 500-ft. level to water-level. One hundred and twenty men are employed. From 1100 ft. in the Victoria, 30 to 35 tons of ore is mined daily. It contains gold, silver, and copper. The raise between the 1050 and 900-ft. levels will make connections in a few days. The Yankee Consolidated management is still prospecting the 200-ft. level in an effort to find the northern extension of the Beck Tunnel-Colorado ore zone, and in addition to this, extensive development is being done on the 2000-ft. level. This is the only mine sending out zinc ore, the last shipment containing 37% zinc. The first carload of ore from the 1000-ft. level of the Tintic Standard has gone to the smelter.

SALT LAKE COUNTY

Owing to the trouble with the bandit Lopez in the Apex mine, 225 men have been out of employment. On opening the mine, after filling it with poisonous fume, the fugitive was not found.

During October, the Ohio mill treated 66,000 tons of 1% copper ore, yielding 720,300 lb. of copper, with a profit of \$14,000. Alfred Frank is in charge of the mine. Readjustments at the mill will be made rapidly, avoiding interruptions in the operations as much as possible, and it is believed that few or no delays will be occasioned. The present capacity of the mill is 1500 tons, and it is said that changes as now planned by George F. Waddell will bring the capacity up to 2000 tons.

Arrangements have been completed whereby the Bingham-Cougar Copper Mining Co. may transport its ores through the Montana-Bingham Consolidated Mining Co.'s adit. This is in about 2400 ft., and will be continued 1000 ft. farther, where several veins may be cut. Eventually the ores from all properties will be handled in this adit, and the drainage will also be made through it. Electric traction is to be used, and probably the mining companies will erect a joint mill.

SUMMIT COUNTY

The Silver King Coalition Co. will pay a dividend of

15c. per share on December 13, amounting to \$187,500. The last shipment made from the American Flag in November was settled for at \$53.37 per ton, divided as follows: gold, \$13.20; silver, \$29.62; lead, \$9.35; and copper, \$1.20. This ore was taken out in the course of development, being stripped from the high-grade ore streak of the Easter vein, which has been left standing intact for a distance of more than 300 ft. The bins at the mine are being filled for another shipment, which will include some of the first-class ore and which is expected to yield a large profit.

Ore shipments from Park City mines in November were as follows, the total being 6471 tons: Silver King Coalition, 2272 tons; Daly West, 2024; Daly-Judge, 1565; creek jigger, 112; American Exploration Co., 102; American Flag, 77; Grasselli Chemical Co., 81; Summit Leasing Co., 61; Silver King Consolidated, 47; Russell and Kline, 38; E. J. Beggs, 25; Thompson-Quincy Co., 36; and Daly Mining Co., 34 tons. During the 11 months of the year, shipments have totaled 74,686 tons. The Daly-Judge will pay \$45,000 in dividends on December 20, making \$108,000 for the year. Connection between the 1000 and 1100-ft. levels has been made in the American Flag, resulting in better ventilation.

WASHINGTON

STEVENS COUNTY

On the 600-ft. level of the United Copper mine, near Chewelah, 500 ft. of drifts have been driven, and stopes have been started. The lower adit is in 3800 ft., having been advanced 315 ft. in November. The new 125-ton mill is working well, and from 10 to 12 tons of concentrate is sent away daily. Thirty-five tons of crude ore is shipped daily to the smelters. Work has been resumed at the Ben Venue mine, three miles north of Meyers Falls. The ore contains gold and silver.

WHITMAN COUNTY

A winter school of mines for metal and coal miners and prospectors, mine foremen, mine managers, and business men interested in mining will be conducted at the Washington State College, at Pullman, from January 5 to April 2, 1914. The staff consists of E. A. Bryan, F. A. Thomson, Elton Fulmer, Solon Shedd, C. C. Todd, F. M. Handy, Hallet R. Robbins, J. H. Pierce, and O. D. Welsch.

CANADA

BRITISH COLUMBIA

Spokane people, headed by D. K. McDonald, are prospecting the Lardo river and have engaged P. E. Seelye to superintend the work. If results warrant it, a dredge costing \$100,000 will be constructed. Net earnings of the Standard Silver-Lead Mining Co. for November were \$91,000. The Granby smelter, at Grand Forks, treated 22,084 tons of ore during the first week of December. Blister copper shipments were 348,000 lb. A quarterly dividend of 3% and an additional dividend of 12% has been declared on the outstanding capital stock of the Hedley Gold Mining Co., payable December 31, 1913.

On November 25 the adit being driven by the Portland Canal Tunnels Co., near Stewart, was in 2500 ft. A shoot of galena has been opened in the Indian mine. Work has been stopped at the Cascade Falls claim for the winter. In addition to the regular monthly dividend of \$50,000, the Standard Silver-Lead Mining Co., operating near Silverton, will pay an extra distribution of \$50,000. During November the Granby smelter treated 106,173 tons of ore yielding 1,944,145 lb. of copper. It is stated that the Granby company will resume development at the Copper Queen mine, on Texada island, which has been opened to 620 ft. and has produced a large tonnage of good ore.

ONTARIO

Bullion shipments from Cobalt for the year total 8,587,964 oz., valued at \$5,940,925. Quick construction has been done at the extensions to the Northern Customs mill, only 105 days being required to erect the 80 stamps, which should be working before the end of the year. Arrangements have been made between the Nipissing, La Rose, and Chambers-Ferland companies relative to draining Cobalt lake. The channel through the Chambers-Ferland will be deep-

ened six feet, so that the water-level may be reduced that depth before pumps are installed in the spring. All proposals connected with this work depend on permission being granted by the mining commissioner, T. E. Goodson. During November the Nipissing low-grade and high-grade mills treated 6334 and 173 tons of ore, respectively, and the refinery produced 576,857 oz. silver. Three small but rich veins were opened at shaft 73, near the Keewatin contact. At shaft 64, No. 3 level, a vein 1½ in. wide, assaying 1500 oz. silver per ton, over 95 ft. in length was opened. The main shaft is 698 ft. deep. The diamond-drill is working in diabase, while hydraulic prospecting is still under way.

YUKON

According to the *Dawson Weekly News*, application for injunction against the Canadian Klondyke company by the Yukon Gold Co., which sought to restrain the former from operating dredge No. 4 on Klondike river at a certain point, was refused November 14. It was claimed that operation of the dredge when the channel was narrow would result in flooding the ground covered by the Yukon shops. The judge decided that evidence of the impending damage was not sufficient to warrant an injunction in view of the relatively greater damage to the Canadian Klondyke company from shutting down. In the course of the hearing, J. W. Boyle stated that No. 4 was yielding 175 oz. gold at a cost of \$600 per day.

CHILE

During November the mills at Braden treated 98,095 tons of ore and produced 8200 tons of concentrate. The copper contained in the ore was 3,038,000 lb. There was 1,596,000 lb. of blister copper produced during the month. The discrepancy was due to the converter having been shut down for several days. The saving in the old mill was 79.4%, compared with 76% in October and 71.2% in September. In the new mill the extraction was 68.2%, as against 63% and 56% in the two preceding months. The ore on which these results were obtained averaged 2.24%, compared with 2.7%, the average of the reserves. The lower extractions obtained in the new mill, compared with the old, is due to the fact that the ore plant is not as fully equipped with Hardinge mills. It is expected that when these installations have been completed the saving in this plant will be equally as good as in the old mill. On one day in November both plants treated 4400 tons, against a combined rated capacity for the two mills of 3000 tons. Dorr thickeners are being installed in the Company's flotation plant.

KOREA

During October the Oriental Consolidated treated 27,178 tons of ore, yielding a total of \$144,137, as shown by the returns of the following mills: Tabowie, \$26,479; Taracol, \$24,508; Kuk San Dong, \$6824; Maibong, \$22,977; Candlestick, \$3950; Taracol tube-mill, \$45,694; Kuk San Dong cyanide, \$7529; Kuk San Dong dump, \$5641; and Candlestick cyanide, \$715. Okura & Co. have completed their power-plant and commenced supplying electric power on November 2, starting with the Tabowie mill. This mill is now driven by Okura's power, as is also the Maibong mill, and all of the machinery at Charabowie mine with the exception of the surface hoist, with which the Koreans are being trained to do electric hoisting. The Tabowie and Taracol mine pumps and all plants at Taracol are operating by Okura's power. The delay at Taracol camp is occasioned by one of Okura's transformers breaking down during the 50% overload test. A cable to the New York office on December 4 gives the November output at \$140,000.

MEXICO

CHIHUAHUA

Bullion valued at \$500,000, the property of the Alvarado Mining & Milling Co., and the Inde Mining Co. of Parral, was recently delivered on the border of the United States by J. Y. Baskin and A. H. Burke. They carried the 617 bars of silver on 10 wagons drawn by 14 mules each, the trip from Parral to Santa Rosalia and then on to La Mula pass and Ojinaga taking 10 days. They were not molested by rebels on the road.

Personal

M. L. REQUA was in New York last week.

R. M. RAYMOND is in New York from Mexico.

ALGERNON DEL MAR was in New York last week.

F. LYNWOOD GARAISSON was in New York last week.

ARTHUR GIBSON is down from Nome for the winter.

J. F. B. ERDLETS, Jr., of London, is in Austro-Hungary.

H. C. HOOVER is expected in San Francisco before Christmas.

B. C. AUSTIN is manager for Flint Mines, Ltd., at Flint, Idaho.

D. W. SHANKS is at Douglas City, Trinity county, California.

T. J. ANDERSON, of Nome, is spending the winter in New York City.

PHILIP ARGALL was in New York and has returned to Colorado.

S. G. WEINBERG, of St. Petersburg, is in this country on a brief visit.

GUY A. R. LEWINGTON is down from Dawson visiting California friends.

T. M. GIBSON was a passenger on the *Senator* from Nome and is now in California.

JOHN P. COSGRO is now associated with the International Machinery Co., at Santiago, Chile.

HOWARD D. SMITH has left London for New York, and will be in San Francisco by Christmas.

ALEXANDER ADIASSEWICH has returned to New York from his trip through the Western states.

A. E. DAUCKER is visiting Shanghai, and expects to be in London by the middle of January.

C. W. PURINGTON has left London for St. Petersburg and expects to return about December 22.

GEORGE P. A. BLANCHIN, president of the Bill Nye Gold Mining Co., was in San Francisco last week.

WALTER G. PERKINS passed through New York on his way back to London from Korea and Siberia.

J. H. BATCHELLER, of the Goldfield Con. M. & T. Co., Goldfield, Nevada, has gone to Mattapoisett, Massachusetts.

D. A. JONES, president of the St. Joseph Lead Co., suffered from a paralytic stroke at St. Louis early this month.

OTTO F. HEIZER is now general manager for the Argo Reduction & Ore Purchasing Co., at Idaho Springs, Colorado.

W. S. KEITH, formerly superintendent for the Helester Mining Co., of San Francisco, is now permanently in Portland.

M. B. BELDEN, lessee of the Robinson Gulch mine in Siskiyou county, California, is spending the holidays in Portland.

GEORGE T. COFFEY, superintendent of hydraulic operation with the Yukon Gold Co., has returned to spend the winter in California.

W. A. CLARK was tendered a banquet in Butte on November 15, which date was the fiftieth anniversary of his arrival in Montana.

JAMES S. COLBATH, recently with the Mines Company of America, has opened an office at Los Angeles for consulting practice devoting especial attention to cyanide work.

F. G. COTTELL, of the United States Bureau of Mines, lectured to the students of the Montana State School of Mines on the 'Electrostatic Settling of Smoke Dust' on November 26.

PHILIP H. MOORE, lately mining engineer and manager for the Canadian Allis-Chalmers, Ltd, mining, crushing, and cement machinery department, has accepted the position of general manager for Rock & Power Machinery, Ltd., with headquarters at Toronto, Ontario.

A. E. WHEELER has resigned as superintendent at Great Falls, Montana, to become consulting engineer for the Union Minere du Haut Katanga, the controlling corporation back of Tanganyika Concessions. JOHN H. KLEPINGER succeeds Mr. Wheeler as superintendent at Great Falls, and MILO W. KREJCI takes Mr. Klepinger's place as assistant superintendent. JAMES O'GRADY will become manager at the smelter, a new position.

The Metal Markets

LOCAL METAL PRICES

San Francisco, December 18.

Antimony.....	10-10½c	Quicksilver (flask).....	\$40
Electrolytic copper.....	15½-15½c	Tin.....	41-42½c
Pig lead.....	4.25-5.20c	Spelter.....	61-63½c

Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.

EASTERN METAL MARKETS

(By wire from New York.)

NEW YORK, November 17.—The copper market is firmer but quiet. Standard spot to March was offered at 14.25, electrolytic at 14.37½, and Lake at 15 to 15.50. The lead and spelter markets are showing a greater activity than has been exhibited for some time, and an increased business is reported. Prices are quoted at 3.95 to 4.05 for lead and 5.10 to 5.20 for spelter. The London spelter market is reported as somewhat easier, due to the arrival in London of large quantities which have been bought for speculation purposes. These had to be disposed of promptly, and as a result the spot price fell a trifle. A good business is reported with the consumers and an improvement is to be noted in the galvanized iron trade.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending

June	61.29	59.03	Dec.	63.38			

Discussing the silver market on November 27, Samuel Montagu & Co. state that at the present time several factors are at work which render the outlook obscure. Usually, some demand arises at this period of the year for prompt shipment to China, in preparation for the customary settlement of debts at the Chinese New Year. As the stock in Shanghai is still so large, namely \$5,920,000, compared with \$5,935,000 last week, no urgent need can exist for supplementing supplies on the spot, and if silver be bought for that quarter, forward delivery would be sought probably by preference. This is suggested by the return of silver for forward delivery to a premium yesterday, after an interval of slightly more than two months' duration. For this reason, the dearthness of money in the closing quarter of this year may be reflected in prices. Further, doubt exists as to the future of what now remains of the stock accumulated by Indian speculators. On the other hand, large 'bear' sales are known to be in existence, the bulk of which materialize toward the close of next month. In all the circumstances, a great amount of competition is not likely to arise for supplies toward the end of the year.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

Date.	Average week ending

May	16.03		15.42	Nov.	17.31		15.08
June	17.23		14.71	Dec.	17.37		

Moderate sales of copper last week served to halt the decline in price. On December 9 Europe was a moderate buyer of electrolytic 30-days at 14½ to 14¾c. per pound. On December 10 fairly good tonnages of February metal were booked here at 14¾c., the London dealers quoting £66 15s. (14.474c.) and doing a fair business the same day. On December 12 domestic buyers took some copper and prices were firm at 14¾c., sales on European account being fair.

Exports for the week ended December 11 were 3245 tons, making a total of 9816 tons, as compared with 11,734 tons for the same period last year. The price at the end of the week was firm at 14¾c. and the sellers are hopeful of larger sales on domestic account before the end of the year.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.	Average week ending
Dec. 11.....	3.90
" 12.....	3.90
" 13.....	3.90

May	4.20	4.34	Nov.	4.91	4.16		
June	4.40	4.33	Dec.	4.20			

The depressing tactics, which were responsible for last week's decline, were not followed up when it appeared that the lower level created was bringing forward buyers more readily, and the ensuing demand soon found sellers rather stiffer, according to Henry R. Merton & Co., writing on November 22. With the advent of a firmer tendency, a better business developed, and up to £19 3s. 9d. was paid for November shipment, and £19 10s. for earlier delivery. Stocks everywhere are very low, and with the Mexican conditions as bad as ever, not much relief is in sight as yet. Toward the close of the week, the surrounding depression again caused a setback, final prices being £17 17s. 6d. to £18 16s. 3d. for foreign, and £18 5s. to £19 5s. for English.

ZINC

Zinc is quoted as spelter, standard Western brands St. Louis delivery, in cents per pound.

May	6.68	5.23	Nov.	7.32	5.09		
June	6.88	5.00	Dec.	7.09			

This has been practically the only metal to show a firm market, according to Henry R. Merton & Co., on November 22. With a better demand for galvanized iron, consumers showed a little more inclination to buy, though business is as yet very restricted. There was also some speculative inquiry for next year, and rather higher prices were paid. Closing prices were £20 15s. for ordinaries, and £21 10s. to £22 for specials.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending	Dec.

Value of gold, \$3,465,380.34.	

Mining in Pennsylvania

Since the first record of mining statistics was written into the history of the United States, Pennsylvania has stood at the top of the list. Exclusive of the value of pig iron and of coke and of other derived or secondary products not included in the total made in the state, the value of Pennsylvania's mineral production is nearly one-fourth that of the entire country, and is only about \$5,000,000 less than the combined outpnt of Illinois, West Virginia, Ohio, and California, the next four states in the value of their mineral prodnction. The value of the mineral production of Pennsylvania reached the enormous total of \$414,426,962 in 1911 and the still greater figure of \$445,790,022 in 1912, according to a statement prepared by Edward W. Parker of the U. S. Geological Survey, in coöperation with the state of Pennsylvania. Pennsylvania holds the leadership primarily on account of her supremacy in the production of coal. The combined value of the production of anthracite and bituminous coal in Pennsylvania, \$346,993,123, nearly equals the aggregate value of all the mineral products of West Virginia, Illinois, and Ohio, the second, third, and fourth states, respectively, in rank. The prodnction of cement was 27,625,340 hbl.; stone quarried was worth \$9,144,214; lime outpnt, \$49,159 tons; sand and gravel, 6,509,333 tons; coke, 27,438,693 tons; and pig iron from outside ores, 12,437,685 tons, valued at \$181,569,299.

Monthly Copper Production

AHMEEK COPPER MINING CO., Kearsarge, Michigan. \$1,250,000 in \$25 shares; 24,796 shares owned by Calumet & Hecla; 1800-ton mill at Hubbell; concentrate smelted by Calumet & Hecla smelter.

Month.	Pounds.	Month.	Pounds.
April	1,503,535	June	1,281,960

Company Reports

TAQUAH MINING & EXPLORATION COMPANY, LTD.

This Company operates in the Gold Coast Colony, West Africa, and the report covers the period from July 1, 1912, to June 30, 1913. The ore extracted from the Taquah mine was 63,591 tons, worth 63.5s. per ton for an average stoping width of 76 in. The treatment plant crushed 61,607 tons averaging 61.79s. per ton. The total recovery for the year realized £179,591, equivalent to 94.35% of the mill-head value. Operating expenses totaled £98,254, the loan account has been reduced to £50,000, and the balance to the credit of profit and loss is £39,698. Ore reserves are estimated at 198,502 tons worth 60s. per ton.

SCOTTISH GYMPIE GOLD MINES, LTD.

The Scottish Gympie company reports the following results of the year ended May 31, 1913:

Ore treated, tons	85,700
Gold recovered, ounces	22,303
Profit	\$38,000
Total cost per ton	4.16

A new treatment plant has been erected in connection with the stamp-mill. Development on the 2100-ft. level cross-cut, at No. 2 shaft, did not turn out as well as expected, and ore from upper levels declined in value considerably.

ANCHOR TIN MINING COMPANY

The report of the Anchor Tin Mining Company of Tasmania, for the year ended March 31, shows that the output was less than usual, owing to an accident to the rock-crusher. The amount of ore from the two mines treated was 86,240 tons, as compared with 104,732 tons the year before. The yield of black tin was 140.6 tons, as compared with 188.3 tons, and the recovery per ton was 3.63, as compared with 4.02 lb. The cost of mining and milling was 98c., as compared with 84c. per ton. About two-thirds of the ore treated came from the Anchor, and the remaining one-third from the Australian mine. The accounts show a net profit of \$270, which was carried forward

THE ROOIBERG MINERALS DEVELOPMENT COMPANY, LTD.

The capital of the Company is £180,000, divided into 180,000 shares of the nominal value of £1 each, all issued and fully paid. The property is at Rooiberg, near Narmbaths, Transvaal. The report for the year ended June 30, 1913, gives the following data:

Ore crushed by 10-stamp mill, tons	21,742
Sand and slime re-treated, tons	14,175
Concentrate produced, tons	1,196
Metallic tin content, per cent.	69.54
Recovery from crude ore, per cent.	72.85
Revenue	£184,868
Profit	88,194
Dividends	63,000
Ore reserves, tons	22,051
Metallic tin content, per cent.	5.32

NORTH BROKEN HILL, LTD.

The North Broken Hill, Ltd., operates a property at Broken Hill, New South Wales. The report for the seven months preceding June 30, 1913, states that during that period 159,583 tons of ore was mined and the mill treated 153,680 tons of ore assaying 15.8% lead, 7.2 oz. silver, and 13.3% zinc, yielding 26,503 tons of concentrate assaying 69.6% lead, 22.2 oz. silver, and 6.6% zinc. The tailing dump has been sold to the Amalgamated Zinc, Ltd., also the production of tailing for ten years from January 1, 1909, and the output of lead concentrate has been sold to the end of 1914. The recovery of metals was: lead, 75.8; silver, 53.5; and zinc, 8.5%. The profit on working account for the seven months was £155,070, com-

pared with £172,334 for the previous term of five months. The output was considerably reduced by a strike of the Silverton Tramway Co.'s employees, which caused a stoppage of railway communication for three weeks. The surplus of liquid assets over liabilities is £190,195. Two dividends were paid, totaling £120,000. The shortage of labor is not so acute as before. Contract miners are earning very high wages, the average paid for the term being \$4.46, and for trammers \$3.56 per shift.

CENTRAL RED, WHITE & BLUE COMPANY

This Company operates a valuable property at Bendigo, Australia, and the report covers the half-year ended September 30, 1913. The main source of production has been from the stopes above the 400-ft. level, and underfoot along the 318-ft. level north. In the latter workings on the hanging wall side gold is seen in breaking ore, and there yet remains a large quantity of highly profitable quartz to take out for considerable distance to the west of the present stopes. The shaft was sunk 160 ft., and stations cut at 800 and 880 ft. Generally the mine is looking well. Results were as follows:

Ore milled, loads of about 3000 lb.	15,418
Concentrate sold, tons	173
Revenue	\$144,000
Dividends	92,000
Costs per ton	2.78

CHILLAGOE COMPANY, LTD.

The Chillagoe company in Queensland, Australia, has had plenty of trouble during its existence. It owns mines, a railway, and reduction works, and during the year ended March 31, 1913, results were as follows:

Ore supplies:	
Chillagoe, tons	26,161
Heberton, tons	2,230
Etheridge, tons	30,511
Cloncurry, tons	87
Metal output:	
Lead, tons	2,841
Copper, tons	2,200
Gold, ounces	9,826
Silver, ounces	272,669
Railway revenue	\$403,000
Railway profit	249,000
Net amount to credit of profit and loss.	78,000

SUPERIOR & BOSTON COPPER COMPANY

This Company operates at Globe, Gila county, Arizona, and the report covers the year ended September 30, 1913. Development covered a total of 5842 ft. The extension of the Great Eastern vein, east of the McGaw fault, has been proved on all levels above the 1200-ft. point. On the 600-ft. level the vein has been opened for 800 ft., varying from 10 to 30 ft. wide. At the extreme east end another fault was encountered, and this was prospected by diamond-drill. The first hole showed an extension of the vein east, at a point 200 ft. further south along the fault. It is 37 ft. wide and contains copper. Six per cent ore has been mined along the foot-wall of the vein on this level. Work at 800 ft. has proved the shoot to be 400 ft. long. Ore deposition on contacts usually occurs in the form of pockets. At 1000 ft., 600 ft. east of the McGaw fault, the vein was cut, and developed for 250 ft. For 100 ft. sulphide ore from 6 to 24 in. wide, with 15% copper, was mined. After that the vein became badly folded and was barren for a considerable length. Work at 1200 ft. was disappointing until fault conditions were studied. Ore mined during the year has come entirely from new shoots east of the McGaw fault. The superintendent estimates that in future he can maintain present shipments of 4000 tons per month. Results were as follows:

Ore mined, tons	15,458
Revenue from ore	\$153,436
Revenue from assessments and interest.	268,502
Mining and equipment	328,052
Note paid	100,000
Balance at October 1, 1913.	75,268

Decisions Relating to Mining

OIL AND GAS LEASE—FORFEITURE

An oil and gas lease providing that it should continue so long as oil or gas is produced on the land, cannot be forfeited for abandonment where the lessees continue to pump oil, though it is pumped in such small quantities as to render the venture unprofitable.

Gillespie v. Ohio Oil Co. (Illinois), 102 Northeastern, 1043, October 28, 1913.

MARL AND FOSSIL DEPOSITS—CONVEYANCE

An indenture under seal granting all the marl and fossil deposits under the grantor's land to the grantee, his heirs and assigns, together with the right to enter and remove the same, is a conveyance in fee and not a mere license revocable at the will of the grantor. Hence it passes to the heirs and devisees of the grantee.

Outlaw v. Gray (North Carolina), 79 Southeastern, 676, October 22, 1913.

DECLARATORY STATEMENT—REQUIREMENT CONSTRUED

The Montana statute requiring that a declaratory statement be filed within 60 days after the preliminary notice of location on a mining claim, which statement shall set forth the number of feet claimed in length along the course of the vein each way from the point of discovery, with the width on each side of the centre of the vein, has been construed as to require, not a description by metes and bounds, but such a description as will enable a person of reasonable intelligence, starting from the discovery point, to readily trace the boundaries as shown by the markings and run the lines. That degree of accuracy is not met if the description given is so erroneous as to be delusive and misleading.

Leveridge v. Hennessy (Montana), 135 Pacific, 906, October 6, 1913.

MINING CO-TENANTS—DEFAULT IN ASSESSMENT WORK

Where one of three mining co-tenants died and neither the administrator nor the heirs of the deceased contributed thereafter to the performance of the annual assessment work, they may be excluded after the usual statutory notice. That notice, however, must be served upon the heirs and service upon the administrator alone is insufficient as the heirs take their ancestor's title subject only to administration. If the heirs have actual notice of their default, however, and neglect to act over a long period of years, it may tend to show an abandonment on their part of all interest in the claim. A suit to quiet title could not in any event be brought by them if they were out of possession. Their remedy if any lies in ejectment.

O'Hanlon v. Ruby Gulch Mining Co. (Montana), 135 Pacific, 913, October 11, 1913.

COAL LEASE—ABANDONMENT

A coal lease, providing that the work of development should commence within ninety days and that if the lessees should elect to mine the coal they should do so within twenty-five years, did not specify the time for developing the mine or the diligence with which mining should be carried on. The lessees put machinery on the land and commenced work, but on account of the quantities of water and sand encountered, ceased it later and removed their machinery, making oral declarations that they were not abandoning the lease, as they had discovered coal. After two years the lessor brought suit to quiet title. Held that the acts of the lessees constituted an abandonment despite their declarations, and that the lease did not give them 25 years in which to commence mining the coal. Procedure with reasonable diligence is an implied covenant. The coal might in fact exist and have been discovered by lessees, but if conditions were such that they could not mine it and they abandoned their work, the lessor was entitled to have the lease declared forfeited.

McColl v. Bear Creek Coal Mining Co. (Iowa), 143 Northwestern, 532, October 23, 1913.

Recent Patents

1,073,076.—METHOD OF TREATING METALS. James A. McLarty, Toronto, Ontario, Canada. Treating metals by exposing metal articles to vapors produced from materials comprising water, an oily carbon compound, and a carbhydrate material, the temperature of such articles being maintained at a point below red heat.

1,073,069.—DRY ORE SEPARATOR. William W. Bonson, Dubuque, Iowa, assignor to Bonson Dry Concentrator Co., Dubuque, Iowa, a corporation of Arizona. A table, a mesh on the table, means for forcing a current of air through the mesh, means for imparting motion to the table, riffles upon the table, and set substantially in a line with the throw of the table, and deflectors upon the riffles at an angle at the riffles.

1,079,107.—ORE CONCENTRATION. George Albert Chapman and Stanley Tucker, London, England, assignors to Minerals Separation, Ltd., London, England. A process of concentrating ores which consists in subjecting to agitation and to the action of a selective agent a pulp of an ore containing a carbonate, in the presence of a bisulphate of an alkali metal, and separating the selected portion of the ore.

1,072,840.—PRODUCTION OF AMMONIUM SULPHATE. Thomas Hill, Easterfield, Wellington, New Zealand. Obtaining ammonia from gases which comprise reacting upon ammoniacal liquor containing ammonium carbonate with calcium sulphate; separating the precipitated calcium carbonate from the solution of ammonium sulphate formed, and thereafter washing gases containing ammonia and carbon dioxide with said solution of ammonium sulphate.

1,072,920.—ROASTING FURNACE. Francis Albert Curnow, Pittsburg, Kansas. In a roasting furnace or the like, the combination, with the furnace, a raking apparatus arranged to stir and rake ore from the furnace, and means for driving the same, of means arranged to be actuated by the raking apparatus for automatically stopping the latter, and means set into operation upon the stopping of the raking apparatus, for automatically starting the raking apparatus after a predetermined interval.

1,072,686.—PROCESS OF OBTAINING POTASH SALTS FROM FELDSPAR. Harry P. Bassett, Baltimore, Maryland, assignor to the Spar Chemical Co., Baltimore, Maryland, a corporation of Maryland. Adding sodium chloride to feldspar or similar potassium containing rock, heating the mixture in the presence of air without the addition thereto of lime or other calcium containing compound to a reacting temperature to render the potassium salts present soluble in water and dissolving out the potassium salts with water.

1,072,732.—ORE AND LIKE SEPARATING MEANS. Pierre Jurien, San Francisco, Cal., assignor of one-half to P. A. Brangler, Agnew, California. Adjoining independently agitatable screens for feeding sized material, a rotatable subdivided receptacle directly beneath the annular series of screens, but placed a substantial distance below the same, means for agitating each of said screens in succession, means for rotating the receptacle to bring its compartments successively beneath each screen, and means of synchronizing the period of successive agitation of each screen with the rotation of said receptacle.

1,075,011.—METHOD OF TREATING ORES AND THE LIKE. Niels C. Christensen, Jr., Salt Lake City, Utah. In the method of treating metalliferous ore, the steps which consist in moistening the crushed ore with a solution containing at least one reagent adapted to react with the ore, roasting the ore, condensing the volatilized products and the acid fumes generated in the roast in another portion of the above referred to solution, and leaching the metal from the ore with said last mentioned portion of said solution.

1,073,463.—FEEDING TUYERE FOR ORE TREATING FURNACES. Ernest Edmund Banes, Strathfield near Sydney, New South

Wales, Australia. A metallurgical furnace fitting, consisting of concentric nozzles with air and gas connections respectively, a hollow fitting concentric with said nozzles, a hollow liner within said fitting and forming with the interior of said fitting a plurality of spiral passageways, an auger screw conveyor within said liner and connections for feeding air and powdered mineral respectively to said spiral passageways and said auger screw.

13,614.—ROCK-DRILLING ENGINE. John George Leyner, Denver, Colorado, assignor to the J. Geo. Leyner Engineering Works Co., Littleton, Colorado, a corporation of Colorado. Rock-drilling engine, the combination with the cylinder and the piston, of a front-cylinder head comprising an integral cylindrical member adapted to be threaded to the end of said cylinder, an axial bore through said head, a counter-bore at its inner end, a chuck-bearing ring rotatably seated in said bore, and a drill-holding chuck rotatably mounted in said chuck-ring, substantially as described.

1,072,904.—RUST-PROOFING IRON, STEEL, OR THE LIKE. Augusto Bontempi, New York, New York, assignor to Bontempi Rust Proofing Co., a corporation of New York. Protecting iron or steel which comprises the step of subjecting the same to the action of the fumes of a fused, non-corrodible, metalliferous substance in a closed chamber, the temperature of the article during the treatment thereof with said fumes being maintained above the fusing, and below the fuming temperature of said substance whereby a non-corrodible deposit is formed in a liquid state upon said article during treatment, substantially as described.

1,073,184.—MUCKING APPARATUS. Walter E. Trent, Reno, Nevada. Combination with a supporting structure of drive mechanism for imparting longitudinal travel thereto, a rotatable tube mounted within bearings on the supporting structure, an elevating scoop secured to the forward end portion of said tube for raising material and discharging the same therein, devices actuated by the drive mechanism for imparting rotation to the rotatable tube and the scoop carried thereby, and independently operated means for imparting longitudinal movement to the said tube during the rotary motion thereof.

1,073,367.—ORE-CLASSIFIER. James W. Shields and Albert C. Thielmann, Hubbell, Michigan. Classified section divided by partitions into a number of pockets, a box removably fitted within the section and consisting of separable sections having lap-joint connection, the said box being divided by partitions, each lying within the plane of one of the first mentioned partitions, the section being provided in one wall with outlet openings and the corresponding wall of the box being provided with openings registering with the first mentioned openings, a screen disposed between the upper edges of the first mentioned partitions and the lower edges of the partitions within the box and dividing the said pockets, an overflow plate adjustable within the box, and means for creating a rise and fall of the material within the pockets of the section.

1,073,218.—DRILLING MACHINE. Eugene Cook, Kalamazoo, Michigan, assignor to National Standard Co., Niles, Michigan, a corporation of Michigan. Combination with the frame comprising a horizontal portion and an upright portion, the horizontal portion being provided with a base at its rear end and with downwardly facing rail engaging hooks at its forward end adapted to co-act with the base in supporting the frame, the upright being provided with a handhold at its upper end; a drill spindle provided with a left-hand feed screw; a driving wheel having a gear thereon splined to said spindle; a feed nut having a gear thereon, a shaft arranged parallel with said spindle, a gear fixed on said shaft and meshing with said gear on said nut; a gear splined to said shaft adapted to be shifted into and out of mesh with said gear on said driving wheel; means for holding said feed nut against rotation, when said gear is shifted out of mesh; a shifting lever for said gear and for said means; a shifting rod provided with a hand piece adapted to be grasped in connection with the handhold of the frame upright; a crank shaft provided with a crank at its rear end; and driving connections from said crank shaft to said driving wheel on said spindle.

The Largest Mine Locomotive

The Carnegie Coal Co. has recently installed at the Charleroi, Pennsylvania, mines two of the largest mine locomotives ever built. These locomotives weigh 30 tons each and are of the Baldwin-Westinghouse bar steel type. It is estimated that each locomotive can haul 100 cars, each loaded with 3 tons of coal, over the local grades. The reasons for using such large locomotives are that a large production is desired and the haul being about two miles long with the grade largely against the load, a large locomotive is required.

The locomotives are described by the makers as follows: Each locomotive consists of two separate units which can be separated and used as 15-ton locomotives if desired. This use of two units in tandem is advantageous in such large machines because the weight is distributed over 8

BALDWIN-WESTINGHOUSE LOCOMOTIVE.

wheels instead of 4, and hence the locomotive has greater tractive power and is also easier on the track than if the weight were more concentrated.

The bar steel construction represents the most modern type of design. As is seen in the illustration, the frames are not built up of plates, but are formed of a grid of steel bars of heavy cross-section. The side frame of each unit is cast separately, forming an extremely strong and rigid construction. The openings in the frame give ready access for inspecting, oiling, replacing brake-shoes, adjusting brake rigging, etc., and also provide thorough ventilation to the electrical apparatus so that its all-day efficiency is higher than would be the case if the frame enclosed it completely. This type of frame has been in use for many years for large freight locomotives, but has been only recently adapted for mine locomotives.

Air-brakes are used, owing to the greater ease of handling so large an engine, but each unit is also equipped with hand-brakes which can be operated from the operating stand of the leading unit. An auxiliary reservoir is provided on the trailing unit, the main reservoir and compressor being on the leading unit. The hand-brakes are operated independently on both units when the two engines are disconnected. The controller for the tandem is of the individual magnetic blow-out type and handles all four motors together. When the tandem is split, the four-motor controller handles the two motors of its unit without change in connections, while the other unit has its own two-motor controller. In addition to the two large haulage units the Carnegie company has installed at Charleroi ten traction-reel gathering locomotives or 'crabs,' also of the Baldwin-Westinghouse bar steel type.

Commercial Paragraphs

H. W. JOHNS-MANVILLE Co. announces that it has increased its office and warehouse facilities at its Cleveland and Baltimore branches.

The SULLIVAN MACHINERY Co. has moved its El Paso, Texas, office to 511 Mills Brg. John Oliphant, for many years president of the Harris Air Pump Co., of Indianapolis,

has joined its engineering staff and will have charge of its pneumatic pumping department.

MEESE & GOTTFRIED Co., 55 Main St., San Francisco, is distributing an attractive Christmas blotter to which is attached a ten-year calendar.

The EASTON CAR & CONSTRUCTION Co., Easton, Pennsylvania, has purchased the stock, good-will, etc., of the Ernst Wiener Co. and will continue the manufacture of cars, railroad equipment, etc.

The WITTE IRON WORKS Co., Kansas City, Missouri, has adopted the plan of selling its gasoline engines and hoists direct to the user and at factory prices. Catalogues and full information will be sent on request.

The JOSEPH DIXON Co., Jersey City, New Jersey, will send on request its booklets written by W. H. Wakeman, dealing with such subjects as 'Steam Traps,' 'Unions for Steam Pipes,' 'Feeding Graphite for Lubricating Purposes,' etc.

The DENVER ENGINEERING WORKS Co. reports the following recent orders of its machinery. The Furukawa Kune mine of Japan is preparing to install a double-drum electric hoist of 500 lb. capacity; the San Juan mines of Buenos Aires, Argentine, have ordered a 5000 lb. capacity double-drum electric hoist complete with electrical equipment; Takata & Co., New York and Tokio, another 2500 lb. capacity single-drum electric hoist for shipment to one of its customers at Moji, Japan; the Zaaipiaats mine in South Africa, a Richards pulsator classifier. Cia. Minera la Lucha y Anexas. El Oro, Mexico, a 10-stamp mill equipment, 1250-lb. stamps, which includes a 4½ by 18-ft. tire and trunnion type tube-mill.

Catalogues Received

WOOD DRILL WORKS, Paterson, New Jersey. Pamphlet, 'Improved Wood Rock Drills.' 31 pages. Illustrated. 6 by 9 inches.

The LUNKENHEIMER Co., Cincinnati, Ohio. 'Lunkenheimer Regrinding Valves.' 23 pages. Illustrated. 3½ by 6¼ inches.

The COOK RAILWAY SIGNAL Co., Denver, Colorado. Booklet, 'The New Storage Battery.' 21 pages. Illustrated. 6 by 9 inches.

THE MINE & SMELTER SUPPLY Co., Denver, Colorado. Bulletin No. 28, 'The Massco Coal Washing Table.' 12 pages. Illustrated. 7 by 10 inches.

HOSKINS MANUFACTURING Co., Detroit, Michigan. Bulletin No. 8, 'Hoskins Electric Furnaces, Type F.B.' 19 pages. Illustrated. 6 by 9 inches.

SULLIVAN MACHINERY Co., Chicago. Bulletin No. 58-P, 'Sullivan Single Stage Power-Driven Air-Compressors.' 19 pages. Illustrated. 6 by 9 inches.

The C. O. BARTLETT & SNOW Co., Cleveland, Ohio. Catalogue No. 42, 'Triumph Crushers, Feeders, Pulverizers.' 31 pages. Illustrated. 6 by 9 inches.

CHICAGO PNEUMATIC TOOL Co. Fisher building, Chicago. Bulletin No. 34-D, 'Chicago Pneumatic Corliss Compressors, Steam Driven.' 32 pages. Illustrated. 6 by 9 inches.

STEPHENS-ADAMSON MANUFACTURING Co., Aurora, Illinois. Section 2, 'S-A' general catalogue, No. 19, 'Power Transmission Machinery.' 110 pages. Illustrated. 6 by 9 inches.

THE PARRAL TANK SYSTEM OF SLIME AGITATION. A description of this well known cyanide treatment. Patents owned by Bernard MacDonald, 1005 Fair Oaks avenue, South Pasadena, California. 33 pages. Illustrated. 6 by 9 inches.

A. LESCHEN & SONS ROPE Co., St. Louis, Missouri. Pamphlet describing construction of the great Elephant Butte dam, drainage in Arkansas, breakwater construction work on Lake Erie, and the tail-rope system of haulage. 11 pages. Illustrated. 8 by 10½ inches.

FORT WAYNE ELECTRIC WORKS, OF GENERAL ELECTRIC CO., Fort Wayne, Indiana. Bulletin No. 1145, 'Type M-L Three-Bearing Belted Direct-Current Generators with Balance Wheels.' 3 pages. Illustrated. 8 by 10½ inches. Bulletin 1147, 'Fort Wayne Transformers, Type A.' 11 pages. 8 by 10½ inches.

EDITORIAL

A MERRY CHRISTMAS and a happy New Year is the wish of the *Mining and Scientific Press* for subscribers and friends. May your stockings be filled with bonanzas and the new year prove a pay-streak from January through December.

RECRUITING methods in Mexico are not conducive to the developing of patriotic and well organized federal armies. After exhausting the jails, the 'press-gang' has been revived and the ranks are being forcibly filled with those who appear capable of bearing arms and who are found on the streets after sun-down. This gives new impetus to the early closing movement among shopkeepers.

THE final installment of Mr. C. B. Horwood's account of 'The Rand Banket' is printed this week together with a letter in discussion from Mr. F. H. Hatch. We have a number of other letters in hand and will hope to receive many more, since such painstaking work as that of Mr. Horwood, and such elaborate presentation of results, entitles the author to careful criticism from his fellow workers. It is planned to reprint the whole series, including the discussion, in book form.

YEAR ENDS are the natural times for stock-taking, and next week we shall print our usual Review Number. In accordance with the traditions of the *Mining and Scientific Press* which seeks to emphasize in its columns technology rather than news, this number will be devoted to a summary of progress in methods instead of résumés of development by geographical districts. We shall print also the statistics for the year so far as authoritative figures are available; but we have no desire to compete with the Government in collection of figures, or to print wild guesses drawn from esoteric sources. Amateur statisticians take themselves seriously at this season. It is well to remember that production statistics are never complete and that averages only by chance coincide with actual transactions.

COMPLETION of the Northern Longitudinal railway of Chile is announced and a through route is now open from La Serena to the Nitrate railways centring at Iquique, with surveys completed to Arica. From La Serena south to Valparaiso the route is over the Southern Longitudinal and connecting lines. Building of this great through line was one of the projects dear to the late president Montt, and he did much to bring it about. While much of the country traversed is barren, many parts are rich in minerals, and, politically, it is of first importance

that the isolated agricultural districts of the transverse valleys should be bound together by transportation lines. The conditions are similar to those which led to the building of the Union Pacific in the United States, and we hope that the similarity may extend to the extent of bringing our Chilean neighbors equal prosperity.

CHINA is so much in the public eye now that we have taken especial pleasure in the printing of the series of views of Chinese mining and metallurgical industries, of which we present another this week. In the main we have been indebted for these pictures to Mr. F. L. Cole, of Shanghai, whose wide travels in the Far East have permitted his making an unusual collection of notes and photographs.

THERE is an old adage which bears upon results when lawyers fall out. We forbear to quote it, but we are glad to print this week a critique by Mr. Robert M. Searls, of the article on the revision of the mining law by Mr. Russell L. Dunn. It is disconcerting for the plain citizen to be told that his arguments carry no weight because he is not a lawyer, and refreshing, therefore, to learn that one gentleman of the bar considers the logic of the other "legal nonsense." Mr. Searls, no more than Mr. Dunn, believes in abolishing extralateral rights, though he sees no legal objection to the change of basis. This being accepted, the matter becomes one of policy, and we take heart again; for as to policy, a layman may argue as well as a lawyer. Not, however, to peril the holiday spirit by controversy, we defer argument on this most interesting point.

CITIZEN'S ALLIANCE demonstrations at Houghton and Calumet are reported to have shown a unanimous expression of disapproval on the part of the law abiding people of those districts against the lawlessness and disorder which has prevailed in the copper region of Michigan. With the machinery of law in order and the grand jury in session a decided improvement in the situation has taken place within the past two weeks, and announcement has been made that the strike will be peacefully conducted in the future. It is evident that the Western Federation of Miners has fallen into decided disfavor in Michigan, and with such a record behind them in the conduct of this strike, there seems little hope that their Washington delegation will be able to accomplish much at the Capital for the good of its cause.

Camp Bird and Its Reinvestments

The career of Camp Bird Limited has been the cause of some surprises, much discussion, and not a little criticism. The report of the annual meeting held in London on November 19 affords much interesting information about the affairs of the Company and gives one at least a glimpse of the reasons for the criticism that has been agitating the financial district of London. Two years ago it was thought that the Camp Bird mine at Ouray, Colorado, was about to yield its last dividend and that the Company would needs go out of existence; but the mine has surprised everyone by its longev-

ity and continued productivity. The general manager, on June 30, 1913, estimated the ore reserves at 31,000 tons capable of yielding a profit of £66,800. The production for the fiscal year just ended had already yielded a net profit of £41,000. Development has proved sufficiently satisfactory to lead to the belief that production may be maintained for some time, and that the mine will die hard. To offset this pleasant surprise on the part of the Camp Bird, the Santa Gertrudis has caused the stockholders great disappointment due to the sudden and unexpected decrease in the value of the ore in the lower levels. Two years ago it was confidently expected that the Santa Gertrudis would yield a profit of £350,000 per year, yet the net profit for the current fiscal year (to June 30, 1913) was only £235,000. This serious discrepancy between actual profits obtained and those estimated by the engineer from the ore developed is explained by the fact that the nineteenth level happened to be driven along a streak where the ore was of a higher grade than that in the rest of the vein. It was not until the stopes had been opened on the entire width of the vein and along the whole length of the orebody that the true average width and value of the ore was found to be materially less than had been estimated, resulting in a reduced tonnage and a much smaller profit for the year. The Company has not given out any information with regard to the twentieth level, except the statement that the vein there is narrower than on those immediately above. Although it may be possible that the mine is approaching the lower limit of the richer orebodies, yet in addition to the vein upon which work has been mainly done and on which a million tons of developed and possible ore are now known, there are some ten other veins upon which little development work has been done. It is possible that Santa Gertrudis may prove to be as long-lived as its forerunner in Colorado. It is unfortunate that the original estimates of ore tonnage and value were unduly optimistic and that detailed figures were given out before the vein in the nineteenth level had been fully developed, for the unexpected diminution in the value and width of the ore on that level has now caused the Camp Bird stockholders much uneasiness; it has depressed the price of the stock, and has given rise to a large amount of caustic criticism of the Chairman and the Board. We are of the opinion that the directors have been unusually far-sighted and efficient in their management of the affairs of the Company, as is evidenced by the dividends paid and the acquisition of new properties from surplus funds. By the judicious purchases of mines of undoubted merit to replace those which are being exhausted, the life of the Company has been greatly prolonged at no additional cost to the original investors. This is a practice which may be highly commended. On the other hand, we do not believe that the stockholders can be expected to place complete confidence and trust in a Board, many of the members of which are directors of financial institutions that have underwritten the securities of other companies purchased by Camp Bird Limited, or have been engaged in developing and securing options upon mining properties that

have later been recommended for purchase by the Camp Bird company. By this we do not mean to imply that the present Board is not above suspicion, but the necessarily Janus-like position of the Chairman and some of the directors may, with justice, cause the stockholders to wonder whether the Board is looking mainly toward personal interests or to those of the Company. Mr. A. M. Grenfell, the chairman, has been greatly exercised over anonymous letters which appeared in *Truth* criticizing himself and the Board. On account of the large portion of his report which is given to the denunciation of his critics, while evidently dodging the question, we are inclined to feel that these anonymous criticisms may not be entirely without foundation. Interlocking directorates, and organization of companies within companies always places the board members in a position where they are subject to criticism. It is difficult to forestall this even by the most complete publicity. In spite of the fact that the stockholders have received excellent dividends and now have a flourishing property, they have not been taken wholly into the confidence of the Camp Bird board. In January 1910, the Camp Bird bought an 81 per cent interest in the Santa Gertrudis for £922,131. It was an excellent purchase, but the stockholders might well wonder at the sum of £244,178 which was paid as commissions to the Consulting Engineer, the Directors, and their friends. In October 1910 it became necessary to raise funds for the further development of the mine and additions to the mill, and therefore 100,000 shares, with calls on a further 135,000 shares, were sold to "third parties"—presumably Mr. Grenfell and his associates—and these shares were never offered to stockholders. When the capital stock was increased in January 1911, the Camp Bird secured an option at par from the Santa Gertrudis on 132,000 of its reserve shares. This option was never exercised, being passed to "third parties," though at a profit, it is true, of £16,800 to the Camp Bird. Since June 30 of this year, Camp Bird has, however, purchased an additional 7475 shares, so that it now owns 74.7 per cent of the stock of Santa Gertrudis company. Why the Camp Bird did not exercise its option on Santa Gertrudis shares and yet purchased later more of the stock, has not been made clear. So what wonder if there are suspicions that commissions and profits in sales of stock may have largely inured to the personal benefit of some members of the Board.

In following out its excellent policy of purchasing new properties from surplus funds, the Company last year took an option for three years on 125,000 shares of stock of the Messina (Transvaal) Development Company, Limited, at the same time guaranteeing the interest on an issue of £250,000 in 6% debentures. The Messina is a copper property which was taken up by Mr. Grenfell and one of his brothers about 12 years ago, and which they have been prospecting, developing, and equipping during that time. From the annual report of the Messina company the mine appears to be doing well and should prove to be a very profitable producer. According to the engineer's estimates, the total probable and possible ore amounts to 480,000 tons.

The ore blocked out averages 10 per cent copper. The Bonanza mine, one of the group, has been developed to a depth of 900 ft. and at that level a cross-cut exposes an orebody 44 feet wide which contains an average of 8 per cent copper across the full width. During the past year 22,600 tons was mined and £94,000 was realized from ore sales, leaving a net profit of £14,000 after paying all expenses, including debenture interest. With the completion of the new 300-ton concentrator and the extension of the railway to the property the Company expects to treat 10,000 tons per month, which should yield a profit of over £200,000 per annum. From the reports we have heard of the Messina it would seem as if the Camp Bird directors had done well in securing an option on some of the stock.

With regard to the advisability of another investment which is now proposed, we do not feel so sanguine. Camp Bird Limited is offered a 40 per cent interest in a syndicate organized by the Canadian Agency—in which Mr. Grenfell is largely interested—to acquire a group of gold mines in Nicaragua, at a cost of about a million and a quarter of dollars. The mines have been examined by Mr. Orvil R. Whitaker, who has strongly recommended their purchase and further development. Mr. Whitaker reports that the aggregate length of the known pay-shoots is nearly four miles and the average width of the veins about 15 feet. He estimates 2,400,000 tons of ore above water-level, averaging \$6.66 per ton, which can be mined by open-cuts and adits, although this is only a very small portion of the tonnage which can be developed. Just because we are not familiar with Mr. Whitaker's name and do not happen to find it among those of the members of the leading mining societies, there is no reason to suppose that Mr. Whitaker may not be an excellent engineer, and one of sound conservative judgment. However, his report sounds almost too optimistic. It is a mistake to include 'possible ore' in a report intended for laymen, for the term is misleading and the estimates of tonnage and value are necessarily approximate only; for instance, Mr. Grenfell gives the tonnage of 'positive and probable' ore, but fails to state that of the positive ore alone, with the result that the impression one receives is that there are two or three million tons of profitable ore in the mine—which may or may not prove to be the case. Inasmuch as we understand that the orebodies occur as lenses from 200 to 500 feet in length, having a maximum width varying from 3 to 30 feet, and are mostly in different veins, it is misleading to give the aggregate length of known pay-shoots, for that implies a continuity which does not actually exist. The mines of the group have been known for a great many years and have been examined a good many times, but the reports on them have not usually been as optimistic as this one. However, we trust that this enterprise will meet with the unqualified success which the Syndicate and its engineers seem to think is assured. Camp Bird Limited, after all, is an unusually well managed Company; the directors have prolonged its life and dividends by judicious re-investments; and the stockholders have had an excellent run for their money. In many ways it is a model which other mining companies would do well to copy.

Successful Salting of Alluvials

By C. S. HALEY

In attempting a disquisition upon this subject, one is minded to take pattern after the famous essay upon snakes in Ireland, which, as will be remembered, began with the pertinent statement, "There are no snakes in Ireland." By the same token, then, there is no such thing as successful alluvial salting, provided: that the examining engineer is honest; that he takes the care, either through his own personal knowledge, or through some absolutely dependable recommendation, that all persons coming in direct contact with the handling of his samples are either honest or directly under the eye of someone who is; and that he use ordinary care, vigilance, and common sense in checking up the results of his sampling.

Preliminary Examination of Alluvials

For an instance, I will take the easiest conditions for alluvial sampling; preliminary examination of an ancient river bed with a view to hydraulic installation. If the deposit is salted, it may lead to the expense of a more careful and, in inaccessible localities, more costly final examination, the result of which might mean a great loss of prestige. In a case of this sort, the examining engineer is apt to make the trip alone, or with one assistant at most; as in all probability his natural inclination, made pessimistic by force of circumstances and experience, is to believe that he is going on a wild goose chase, and should be accomplished with as little loss of time and money as possible.

Arriving at the neighborhood of the property, it is worse than useless for him to attempt to conceal the nature of his business. In these our United States, so neighborly is the interest felt in all the operations of our brother, the chances are that the proprietor of the hotel in which he rests his stage-worn bones on the first night of his journey, has been telephoned in advance of the nature of his errand, and in the course of his evening's wait he will have all sorts of information gratuitously offered him. If, however, our engineer be not too young he will not shun this information thus thrust upon him, but may derive a great deal of keen amusement therefrom. For in even the most isolated mountain communities the knockers thrive as well as the boosters, and he is very like to hear a composite description of the property which he proposes to examine which will be very like to a eubist picture; viewed from one angle, a radiant vision of a glorious dawn; from another, a dark-brown taste on a foggy morning. From such an extreme double characterization, by noting the points overemphasized, he can often determine a course of action, subject to modification on the ground, which will perhaps aid him to the saving of much time. On the other hand, he may decide it best to let it all pass with a 'warming of the head,' as our Latin-American friends very aptly put it, and forget all about it.

Arrived at his destination, and well aware that the object of his trip is a matter of discussion to the

entire country-side, it may be well that he does not look upon the men whom he hires to attend to the rougher portion of the work as being like unto Caesar's wife. It may be necessary to run an open cut into the bank, and down along the rim of the channel; or, in the case of a working face, to strip a cut from top to bedrock. In all of this work, there is the easiest chance in the world to salt samples, provided that the engineer is careless and easy going. On the other hand, if he appears to be very in-souciant, the chances are that by keeping a watchful eye beneath such an appearance, he can detect much more than if he preserves the air of extreme vigilance. Most salting in such places is very clumsily done. For instance, if you give a man a sample to pan down for you (intending, of course, to pay no attention to the result), you may observe him smoking with his pipe tipped sideways over the pan, or spitting tobacco juice nonchalantly into the pool in which he is panning. But this kind of thing should never be noticed openly. Simply give the man enough rope, and he will hang himself, and you will avoid a great deal of unpleasantness, and possibly the necessity of doing, or receiving, physical harm. One should always remember that the last laugh comes with the report. And, no matter who is handling the manual work of the sampling, always take check samples yourself, from a face exposed by yourself, and pan them yourself, with nobody else within five feet of you.

An Unsuccessful Attempt

So much for this type of sampling, which is very simple, and does not necessitate, in the case of an experienced engineer, any weighing of samples. In connection with this work, I am minded of a tale they still tell in Yreka of two gentlemen of fortune who attempted to dispose of a worthless placer claim to a Chinaman! After very carefully disposing of about five hundred dollars worth of wash gold about the exposed face of the workings with a shotgun, they offered the property to Wun Lung, who had recently disposed of his laundry and pi-gow house, for five thousand dollars cash. Wun Lung very cheerfully consented to enter into negotiations, but requested a day to work the property, to determine its worth. This was, of course, readily accorded him. At the end of the day, the prospective purchaser expressed himself as very well satisfied, but wished to wait two more days before paying over the five thousand. With the lure of easy money in their eyes, our gentlemen of fortune readily assented. On the time appointed, however, the Celestial failed to materialize; in fact, he could not be found in the town. The owners of the property, stricken with a sudden panic, went down to their diggings, and found their worst fears realized. The carefully scraped banks showed them whither had departed their \$500 worth of dust, and they returned to town to walk in the virtue of the chastened.

This kind of thing is, of course, clumsy; so clumsy that it often defeats itself; as in a case mentioned in *The Mining Magazine* some years ago, where a young man went out to sample a gravel property, and, in spite of the fact that the promoters managed to slip at least ten cents worth of gold into every pan that he took, he reported the property as valueless simply for the reason that he panned all the gold out and even had no black sand left at the end of his panning!

Keystone and Empire Drilling

In the case, however, of Keystone and Empire drilling, much more artistic work can be done. For this reason, the panner on the drill, or at least one of them, should always be a man absolutely trustworthy and personally known to the examining engineer. In case of any irregularity on the other shift of the drill, it may always be checked by the work of the absolutely trustworthy shift. One very ingenious method of salting a Keystone that has come under my notice has been the plastering of the drill rope with mud containing plenty of No. 3 colors. In this manner the *de trop* gold was carefully and evenly distributed throughout the hole. A watchful drill-runner, who felt the fine flakes of mud dropping round him as they dried, spoiled this little plan very effectually, however.

A drill fireman with the tobacco habit spoiled his game once by spitting too consistently into the box as he lowered or raised the sand-pump. The clumsiest attempt that I know of in this connection was the deliberate spilling of gold on top of the ground after the machine had been set up and the careful salting of panning tubs and boxes. The simpleton did not even take the trouble to use the same type of gold that was ordinarily found in the bar!

Drill Sampling

In drill sampling, however, there is this big advantage over open-cut sampling; that you have a continual check on the weight of your gold by the panners' log. In open-cut sampling, where possibly samples are only weighed once in two or three days, unless the samples are very carefully guarded, it might be very easy to augment the sample; and, as the colors have only been scanned once, and then as a lump sum, a careful job might raise the value of the property several cents on the yard. But in either case, until all samples are weighed up and checked, the utmost care should be taken in guarding them. Usually, in the case of a property extensive enough to justify a Keystone examination, the amount of money involved is big enough to induce men of a certain type to take extraordinary chances.

Of course, in the long run, the most effective way of salting alluvial, as well as other property, is to buy the examining engineer; but this, too, presents its difficulties. If the report is to be worth anything in the eyes of practical mining men, it must be made by an engineer of standing. And, in most cases, that standing is the result of long years of honest work and toil-won experience. Therefore, the man who would barter it, even if he would barter that incomparably more priceless thing, his self-respect, would

probably demand so high a price that the promoter's profit would be more than wiped out. For of necessity, to a man who has lived an honest existence as far as the maturity of his life, the prospect of not being able to hold his head high for the balance of his career, is hard to assess to him in financial terms.

In conclusion, one of the most effectual methods of salting a gold mine that ever came under my experience, was not done with gold, but with frogs! The promoter of the property, which was once a famous producer in 'the days of old,' etc., was making a strenuous effort to sell a worked-out mine. His prospective buyers were Frenchmen, and the whole incident came under my personal observation. The price was moderate, the gold was fairly evenly distributed, and there was a fair chance to sell. However, instead of making the mistake of trying to prove the impossible, my friend left the subject of available and workable ground strictly alone, and expatiated on the value and beauty of the place as a summer camp. Then he led his buyers down to a deep and spacious pool of stagnant water in the bottom of an abandoned, worked out diggings. It was a sort of a frog concentrate, and the rest of the mine, from a frog standpoint, was not to be judged by it. At the opportune moment, nets were produced, and before his clients left that summer afternoon, they were begging him to accept a check to bind the bargain.

After an existence extending over 16 years the Hartley & Riley Beach Dredging Co., of Cromwell, Otago, New Zealand, has been voluntarily wound up. This course was adopted in consequence of the poor prospects, and in consideration of the fact that, so far as the river conditions were concerned, it was thought to be impossible to continue work for several months at least. The Company held an area of 32 acres, the material worked upon being at an average depth of 35 ft., and the quantity raised per hour averaged 100 cu. yd. In 1905 two acres yielded 674 oz., and the total gold produced was 29,618 fine ounces, the value of which was \$600,000; while dividends amounting to \$400,000, equal to \$63 per share, have been paid, on a paid-up capital of \$30,240, which was also the cost of the dredge employed. For the week ended March 23, 1900, the dredge yielded 1187 oz. 14 dwt. of gold, and for the week ended October 16, 1903, 1158 oz. 19 dwt. was secured. The dredge holds three records in New Zealand: for the gold return for a fortnight, for one month, and for the total dividends paid in one month. The 1234 oz. won by the Electric Gold Dredging Co. still remains the record for a week's dredging in the country. In the days of the dredging boom, the Hartley & Riley company held place of pride for the price of its shares, on one occasion \$4.80 shares rising close up to \$115.

Block tin and tin ore weighing 32,747 tons was exported from the Malay States during the first eight months of 1913.

For producing cobalt oxide, three Ontario companies received a total of \$10,000 in bounties last year.

Dredging at Snelling, California

STAFF CORRESPONDENCE

While Merced county is essentially an agricultural and fruit-growing district, yet an interesting dredge is working on the south bank of the Merced river, not far from the county line. Shortage of water has caused the stoppage of several dredges in other counties, but the one owned by the Yosemite Dredging & Mining Co. has operated continuously, handling up to 100,000 cu. yd. of gravel per month. Feeders to the Merced river are said to have a sharp fall, consequently any little precipitation of rain, or melting of snow in the mountains, keeps the river flowing at a fair rate, although at present it is certainly low.

Operating Conditions

The conditions under which the Snelling dredge

last from 10 to 12 months. Instead of having the usual revolving screen, a shaker screen is used, while the ordinary gold-saving apparatus and stacker belt are installed. The following electric motors are in operation: 50 hp. on the bucket line, 20 hp. on the stacker, 20 hp. on the shaker screen, 40 hp. on the 8-in. centrifugal pump for washing, etc., 15 hp. on a small winch, and 5 hp. for priming and small pump work, a total of 150 hp. This dredge has an exceptionally high load factor and average working time, these being 78 and 90%, respectively. This is not mere calculation or time given by the dredge crew, but actually shown on a General Electric recording ammeter in the office away from the dredge. The yardage handled, 1,020,000 cu. yd. in 1912, is surveyed every month, so here again approximate statements are not relied upon. The boat works three shifts per day with a crew of two men on each, except day shift, when a few extra men are necessary for repairs, etc. The men are well looked

YOSEMITE DREDGING & MINING CO.'S DREDGE ON THE MERCED RIVER AT SNELLING.

is working may be said to be difficult to equal. The river flats consist of two to five feet of sandy loam above the gravel, the average depth of the bank being 15 ft., of which 11 ft. is below water, resting on a bedrock of 'lava ash' which underlies this part of the district. Scrub, fair-sized oaks, and cottonwood trees grow in the area, the roots being badly matted together and giving the dredge some hard work at times. There is always about four acres of land cleared of growth ahead of the dredge. The gravel is ordinary river wash, with stones from six to eight inches diameter, with a few up to ten and twelve inches. As working in the actual river bed is not permitted, the dredge is floating in a pond, separated from the river by a levee a few feet wide. Water is let into the pond by a small ditch fed from the river where it is dammed. Power is supplied by the San Joaquin Light & Power Co. at 1¼c. per kilowatt-hour.

The dredge is of the Bucyrus make, with 3¾-cu. ft. close-connected buckets, the lower tumbler of the ladder weighing 5000 and the upper 6000 lb. Manganese steel lips are fitted on the buckets and last 18 months, the bucket bottoms being in their third year, while the wearing plates on the tumblers

after, receive high wages, are paid for time off during sickness or holidays, and, consequently, efficient work results.

An interesting feature in operating this dredge is that there are no spuds used at all, the ground being unsuitable, so a head-line is maintained to keep the digging ladder against the bank of gravel. At each of three points on the cleared ground is anchored a 1¼-in. diam. steel wire rope about 400 ft. ahead of the dredge. Attached to a winch is a cable of the same size and this and any one of the other lines is joined by a shackle and pin, so that, when digging at either side or middle of the pond, the head-line is almost straight ahead and it is not necessary to move the whole length each time a new position is made, but just change from one anchored line to another. The usual side-lines are used for lateral movement.

The average recovery of gold is 10 cents per cubic yard, and over 350 acres of land has been turned over to date. J. H. White is manager of this economical and interesting dredge, and is experimenting with the recovery of fine gold and platinum from the dredge pulp after it leaves the tables. James W. Neill, of Pasadena, controls the property.

The Rand Banket—Part VII

By C. B. HURWOOD

Genesis of the Pyrite and Gold in the Bankets

In the year 1903 De Launay³³¹ summarized the various theories with regard to the genesis of the gold and pyrite in the auriferous banket of the Rand and grouped them under the three following heads, according to whether it was assumed that the gold was formed (a) before the banket; (b) during the deposition of the banket; (c) after the banket had been deposited.

The theory that it was formed during sedimentation is now generally discredited, and has been discarded. The placer theory, which assumes that it was formed before the banket, seems at first highly attractive; it was last presented, in 1907, by Gregory in an interesting, suggestive, and valuable paper,³³² in which the work done and the writings on the subject to date were ably summarized. As he admits, this paper was the result of his observations during a short visit to the Rand in 1905, and of information and ideas obtained second-hand on that occasion. As might, therefore, have been expected, his arguments were far from convincing and were ably opposed in the subsequent discussions with the result that the theory of a placer origin for the gold, far from being proved, was shown to be improbable.³³³ At the time those, perhaps, best able to judge, who had for many years studied the question on the Rand itself, were almost unanimous in agreeing that the gold was introduced subsequently, that is, after the conglomerates were already formed. The work done since then amply supports and confirms this opinion, which may now be said to be held by all those qualified to judge who have, on the Rand, given the matter prolonged and serious study; and especially by those who have studied the subject by continual observations taken at first-hand underground, supplemented by microscopical investigations and chemico-physical research work in the laboratory.

De Launay's Theory

It may here be well to recall that in the year 1903 De Launay³³⁴ in discussing the theory under the third heading, that is, of the introduction of the gold into the bankets after their formation, pointed out that if this be accepted one has to deal with a special type of lode formation. The solutions instead of circulating, as usual, along rock-fractures, insinuated themselves into the interstices between the pebbles of the auriferous bankets and there deposited their mineral contents; and although the process must have taken place on a much larger scale, yet it is somewhat analogous to the case of the cinnabar deposits of Almaden, in Spain, where sulphide of mercury, accompanied by silica and hydrocarbons

and a little iron sulphide, impregnated what were previously porous layers of sandstone along the entire extent of certain strata. In other words, the gold-bearing pyrite is a product of metamorphism similar to that which formed the chlorite or muscovite of the bankets. The Rand ore deposits are thus a simple, but particular, case of the type of deposit represented by the various formations of South Africa that carry gold-bearing pyrite: they are the result of a subterranean impregnation, produced under pressure and in depth by mineralizing waters from an eruptive magma. He admits that this theory affords a good explanation for variations in the grade of the ore, in following the line of the outcrop from one claim to another; and likewise for the relative uniformity of zones, rich or poor, in sinking on the dip: while as already stated, the placer hypothesis would require a uniformity along a line parallel to a primitive coast and a progressive decrease in richness as distance is gained transversely to the shore. His most serious difficulties, as regards this theory, were that it gave no clue to the presence of the 'rolled' pyrite; and "is scarcely in accord with the general appearance of the pyrite grains, as they are seen under the microscope." These difficulties have already, in the first three parts of this paper, been shown to be really non-existent. The author has visited and studied the occurrence at Almaden and there is no doubt that the cinnabar impregnation of what were formerly sandstones, but are now quartzites, was due to the agencies of the neighboring intrusive rocks; and he agrees with the appropriateness of the analogy as described by De Launay.

Placer Theory of Formation

When the writer first went to the Rand he was attracted by the seeming simplicity of the placer theory, which he at first accepted. He was soon, however, forced to abandon it as incompatible with observed facts; and only after more than ten years of close, constant, and prolonged study does he feel justified in presenting to his readers the results of his researches here recorded. Constant study underground of the actual occurrence of the gold in the banket soon revealed numerous features that cannot be explained by any supposition of a placer origin. The figure (21) printed in part IV shows an example of one of these. It illustrates how when a pebble leader entirely dies out the hanging and foot-wall quartzites are sometimes separated by a thin layer of gold, just as frequently happens when ore pinches in a normal gold-quartz vein and a thin streak of gold persists between the two walls.

Posepny³³⁵ pointed out that the average density of the earth is 5.6, while that of the rocks of the earth's crust is only 2.5, and that consequently it must be admitted that in the central mass substances much denser than 5.6 have been accumulated, that is to say,

"the deep region is the peculiar home of the heavy metals." He then continued, and, here it will be well to recall his words: "If we imagine ourselves standing in the deep region in front of the profile of an ore-lode, like the Adalbert at Przibram, for instance, 1110 m. (3600 feet) below the surface and 564 m. (1850 feet) below sea-level, we perceive a fissure space of discission, filled with symmetric mineral crusts, chiefly argentiferous lead sulphide. Remembering that this filling has been stoped continuously to the surface, we can find no other satisfactory explanation than the hypothesis that it was brought up from still greater depths, and, in view of the comparative insolubility and the large quantity of the metallic sulphide here accumulated, it must have been deposited from perpetually renewed, and, therefore, from *ascending*, mineral solutions. Whoever has had opportunity to study an ore-lode in the deep regions can conceive no other explanation. The miners themselves have always held this opinion; in other words, they have all been ascensionists." He added that in considering the genesis of an ore deposit formed in a pre-existing space where crustification is absent, and therefore the manner of filling is not immediately apparent, recourse must be had to the analogy of the substances and their paragenesis; if these correspond with the contents of spaces filled with crusted deposits, a similar origin must be inferred, as for example in the case of certain metasomatic deposits. He maintained that "from these considerations it follows that all the deposits of the deep region are referable to one general ruling process, clearly shown to be the action of ascending mineral solutions; that is, they were all formed by ascension." Discussing the Przibram veins he stated that in that district sedimentary rocks are traversed by heavy eruptive masses, which are 30 metres thick by the main vein, and 100 metres for the whole group of veins; and even Sandberger³³⁶ admitted that "an essential part of the lead and silver contents of the ore-veins is due to the eruptive rocks." Posepny asserted that the veins might be ascribed to the contraction of the eruptive dikes in which they occur, although they depart, here and there, into the stratified rocks; and that "we cannot dream of deriving their metallic filling from the dikes. The Commission, already mentioned, established to test the applicability of the lateral-secretion theory to Przibram conditions, found the material of the dikes to be the same in depth as in the upper zones. The largest amount of metallic contents attributed to the diorite dikes would account for a portion only of the thickness of ore in the veins. The greater part must certainly be regarded as of deep origin; and it is more convenient to treat the entire metallic contents of the veins as derived from greater depths." Further, that at Przibram, in central Bohemia, above the granite foundation lies a formation of pre-Cambrian slates, unconformably overlying these is the Cambrian system, consisting below of conglomerates

and sandstones, and above of fossiliferous slates. The ore occurs in the Cambrian sandstones. Diorite dikes are numerous; their strike making an angle of 45° with the prevailing strike of the sedimentary beds. The veins are mostly in these dikes, only occasionally entering the stratified rocks and returning soon to the dikes they have left, or to others of the group. Also, he stated that in dip they mainly follow the dikes, and the latter determined the formation of the "ore-bearing vein-fissures;" and, that if the vein material (as is very likely) was derived from eruptive rocks, these were much deeper than the eruptive rock disclosed down to the then bottom of the mine (or 3640 ft. below the surface). The rich ore-ground is in that more highly metamorphosed portion of the Cambrian sandstones near the main structural fault, which had then been disclosed by mining to a depth of 3600 ft. The rich ground, therefore, starts from the intersection of this fault with the zone of eruptive rocks, in other words, from the point relatively nearest to the barysphere. Both the veins and the dikes are fissure-faults. The dikes present different kinds of eruptive rock, and are generally decomposed in the neighborhood of the ore-veins, which, as Posepny is careful to point out, is "a result naturally to be attributed to the action of the mineral springs." He states that the general rule (which the present writer believes is now almost universally accepted) is that ore deposits carrying metallic sulphides have been formed by ascending solutions. He also stated that "the Przibram district lies, in round numbers, about 500 metres above sea-level, and the mine workings extend, as is well known, to more than that distance below sea-level. The ground-water level is but a few metres under the surface. The deepest adit drains the mines to about 100 metres; and everything below that level is strictly deep workings, from which the water is lifted to the adit-horizon. A comparison of the water raised from different levels shows that the largest quantities come from the upper ones, and that the amounts diminish with increasing depth, so that at about 300 metres below sea-level no water remains to be raised, the ruling rock and air-temperature of about 23°C. (74°F.) at that depth sufficing to evaporate the small existing quantity of water. This is certainly a striking proof that the water encountered in mining is of atmospheric origin." The present writer has visited Przibram and studied the deposit underground, and has quoted Posepny's discussion on it in some detail because he (the writer) considers that in many ways this occurrence is, in essentials, analogous to the gold deposit of the Rand. In each case the extension in depth is great, the lower portion of the mines is dry, the lodes occur in ancient quartzites overlying granite and pre-Cambrian schists,³³⁷ and are genetically connected with main structural faults, and with basic dike intrusions that represent fissure-faults. In both instances the dike-rock is generally decomposed in the neighborhood of the orebodies, and contains the chief minerals of the ore. In the Przibram case the associated minerals are iron pyrite, chalcopyrite,

³³⁶Posepny (*loc. cit.*, p. 60) pithily remarks that Sandberger's theory of lateral secretion "found many disciples, especially among mineralogists, because it permitted the most extensive genetic generalizations, without requiring the observer to leave his mineral collection and laboratory, to descend into the mine, and to study the ore in the place of its origin."

³³⁷What are termed sandstones in Posepny's description are really quartzites; and the pre-Cambrian rocks largely consist of schists.

arsenical pyrite, calcite, zinc-blende, sphalerite, and siderite; and in the lower levels the galena contains less silver and is largely mixed with quartz. Thus the associated minerals are sulphides in both deposits; and the latter doubtless owe their mineralization to the magma from which the dikes are derived. If the reader will now try to imagine that he is standing in the bottom of the Jupiter mine, in front of the profile of the blanket lode, about 5040 ft. or nearly one mile, vertically below the surface, and about 430 ft. above sea-level,³³⁸ he will not, as in the case of the Adalbert at Przibram, see a fissure-space of discission filled with symmetric mineral crusts; because here we have a channel that afforded a freer circulation to the mineralizers than fissures; and as its walls were kept apart by intervening pebbles their presence naturally prevented the structure assuming a crustified form. Remembering that this orebody has been stoped continuously to the surface the reader will more readily admit that, as in the Przibram example, there can be no other satisfactory explanation of its origin than that the gold and its associated iron sulphide were deposited from constantly renewed up-rising deep-seated solutions.

Not a Placer Deposit

Thus among other features which militate against the theory of a placer origin of the Rand gold deposit and which may, on the other hand, be regarded as evidence that it is merely an abnormal type of lode deposit may be mentioned the great depth to which the profitable ore extends; and, the dryness of the mines in depth.

Other convincing facts are, the abundant evidence of former water-ways whence mineralizers could have ascended; the crystalline character of the gold;³³⁹ the close association and relationship of the gold and pyrite; the occasional association of the gold with vein-quartz; the occasional presence in the auriferous blanket of small quantities of calcite, tourmaline, or such vein-minerals as galena, blende, copper pyrite, and pyrrhotite.³⁴⁰ Also, the occurrence of pyrite 'pebbles,' which in the first three parts of this paper were described and shown to be associated with dike intrusions and to be products of metasomatism. Other characteristics indicating the lode origin of the auriferous blanket (which were dealt with in part IV) are the shape of the pebbles due to their

mode of growth; their association with rich ore; the influence of slates and shales on the mineral deposition; and the association of the gold with traces of iridosmine and other metals of the platinum group. Still others, discussed in parts V and VI, are the manner of distribution of the gold and the various local indications of good ore.

The theory of a later infiltration of the gold being accepted, it merely becomes a question as to what agencies are due the introduction of the mineralizers into the auriferous blanket. Also whether there were one or more periods of mineralization; that is, whether the gold in the bedded quartz veins of the Dolomite formation of the Lydenburg and Pilgrim's Rest districts in the Northern Transvaal, and of the bedded quartz veins, and also the blanket of the Black Reef formation (which underlies the Dolomite), and of the blankets of the much older Witwatersrand system, belongs to different periods or was introduced during one great period of mineralization.

Genesis of Pyrite

In considering the genesis of the pyrite and gold in the auriferous blankets of the Rand, it cannot be too strongly borne in mind that the latter really differ in no important essentials from ordinary gold-bearing quartz veins. The solutions have merely found these beds sufficiently pervious, to select them rather than fissures for circulation and precipitation of their mineral contents. These channels have finally been closed to further mineralization by the deposition of secondary silica, which is analogous to the vein-quartz of an ordinary lode. In a similar manner ordinary quartz veins have been sealed by the deposition of vein-quartz and other gangue material. As long ago as 1890, six years after the discovery of the Rand, J. S. Curtis, formerly of the United States Geological Survey, evidently considered that the basic dikes of the Rand were connected with the mass of basic eruptive rock composing the Heidelberg range some 30 miles southeast of Johannesburg; and he expressed the opinion that the gold and pyrite of the blankets were due to the intrusion of these rocks. He wrote "These dikes are intrusive, usually, following the dip and strike of the formation, but occasionally they fill cross-fissures and fault the reefs. They outcrop in many places in the basin as well as in the Heidelberg range. This greenstone is most probably diorite,³⁴¹ and to its eruption the uplifting of the Rand is not only attributable, but I also believe that the solfataric action incident to its outburst has caused the formation of the gold deposits." He stated that he first visited the Rand in March 1887 with Gardner F. Williams, who had been in the district before and who maintained that the gold was not alluvial but was quartz gold deposited after the blankets had been tilted into their present position. Since then Curtis has resided near Johannesburg and has often had occasion to examine the most important seams of blanket, and as a consequence he has

³³⁸G. H. Thurston, of the Consolidated Gold Fields of South Africa informed the writer that the height of the collar of the Catlin shaft above sea-level was 5470 ft.; and that at June 30 (1913) the vertical depth of the bottom of the lower, inclined portion of the shaft below the collar was 5040 ft. He also told him that in sinking the shafts for this mine the Main Reef was struck in the Howard shaft at a vertical depth of 3528 ft.; and at a vertical depth of 4092 ft. in the Catlin shaft; and that the average dip of the blanket is here about 38°.

³³⁹The grains of gold are often of very irregular shape, with hackly surfaces and jagged outlines.

³⁴⁰Even R. B. Young, who seems loath to admit that the basic dikes have any bearing on the origin of the gold in the blankets, writes: "blanket and quartzite at their contact with dikes are sometimes crowded with well formed crystals of pyrite" and, "I am told, on reliable authority, that sometimes the proximity of a dike may manifest itself in the appearance of a noticeable quantity of chalcopyrite, galena, and pyrrhotite in the pannings of the blanket." R. B. Young (1909), *loc. cit.*, p. 89.

³⁴¹We now know that the Heidelberg range is composed of diabase and belongs to the Ventersdorp system. The strike dikes of the Rand also consist of diabase; and there can be little doubt that they are genetically related to this same rock system.

stated that he has come to the conclusion that in many of their characteristics they closely resemble lodes.³⁴² Much later he wrote "The earliest evidence of solfataric action is that which was subsequent to the great eruption of basic igneous rock which tilted up the Witwatersrand beds; and the eruption was a very long period after the deposition of these beds," and also "If the theory of infiltration is accepted, as accounting for the presence of gold in quartz veins, there seems to be no valid reason why the presence of gold in the banket should not be accounted for in a similar manner."³⁴³

Influence of Dikes

Had the analogy not been masked by the fact that the lodes are composed of ordinary sedimentary conglomerate, which has suffered considerable metamorphism, the similarity would long ago have been generally recognized and the mineralization would have been ascribed to the direct or indirect influence of the older, or longitudinal, series of dikes and to the magma with which in depth they are connected. These dikes³⁴⁴ contain pyrite and gold and are much in evidence throughout the mines of the Rand, as those whose work has necessitated their frequent presence underground in these mines fully appreciate. As the writer has pointed out, they furnish abundant and sufficient evidence of former deep-seated communications whereby the mineralizers could have ascended.³⁴⁵

It has already been shown that the pyrite was deposited late in the history of the banket, probably in part simultaneously with, and also continuing after, the intrusion of the big longitudinal diabase dikes that occur throughout the Rand. Active mineralizing solutions, as one would expect, still continued to circulate for awhile after the dikes had solidified. In the case of the Crown Reef, the connection between the presence of pyrite replacements and dike intrusion was apparent; and there are many instances where the influence of dikes on the richness of the neighboring banket is generally admitted; the Ferreira-Crown Deep dike is a good example. The close relationship between gold and pyrite and gold and carbon in the lodes of the Rand

is admitted; the way in which the gold is frequently interlocked and enveloped in pyrite or carbon indicates that there has been simultaneous precipitation of these substances; the striking association of pyrite replacements; of carbon; of black, black-edged, and pink pebbles; and of blackened quartzite and rich ore has been clearly emphasized. The author elsewhere³⁴⁶ has shown that the longitudinal basic dikes contain the characteristic minerals and elements of the auriferous banket, namely gold, silver,³⁴⁷ pyrite, and carbon.³⁴⁸ He has repeatedly called attention to the evidence indicating that the origin of the gold in the banket is due to the dike intrusions having opened deep-seated communications whence the mineralizers have ascended.³⁴⁹ He also showed that the carbon, which, like the pyrite, is so intimately associated with the presence of gold, is derived from magmatic vapors, or solutions, emanating from these dikes as a consequence of their intrusion.³⁵⁰ Also³⁵¹ that in examining under the microscope thin sections of ore in which carbon is present, from the Buckshot Reef and Carbon Leader in the Rietfontein mines, from the Randfontein Leader in the Randfontein mines, and of ore from the Buffelsdoorn mine near Klerksdorp, all of them mines in which the occurrence of visible carbon in the ore is characteristic, the most noticeable features are the intimate association and intergrowth of the carbon with gold, the latter not only occurring round the carbon grains, but also sometimes as particles entirely surrounded by carbon, while the carbon grains often contain minute specks of gold scattered through them; the frequent and close association of the carbon and pyrite, which is particularly noticeable in the Buckshot Reef; the frequent association of sericite with free gold and carbon; and the actual replacement of quartz by carbon both in the matrix and in the pebbles. This, together with what has already been written in this paper with regard to the metasomatic origin of the pyrite 'pebbles', or replacements; and with reference to the occurrence and distribution of the gold in the bankets; of local indications of good ore; and of the intimate association, frequent inter-growth, and often more or less simultaneous precipitation of the gold, pyrite, and carbon, all clearly show that one has, here, to deal with a deposit formed by processes in all essentials analogous to those that have operated in the case of ordinary gold-quartz veins.

Stages of Mineralization

The following considerations will help the reader to understand the obvious stages by which this min-

³⁴²'The Banket Deposits of the Witwatersrand,' by J. S. Curtis, *Eng. Min. Jour.*, Feb. 15, 1890.

³⁴⁴These dikes vary in thickness from about 4 or 5 ft. up to 400 ft., and sometimes even more.

³⁴⁵C. B. Horwood (1905), *loc. cit.*, pp. 35 and 62; (1910), *loc. cit.*, pp. 42 and 43; (1910), *loc. cit.*, p. 76; and (1912), *loc. cit.*, p. 58.

The unprofitable banket beds are analogous to the barren quartz-veins, which so frequently occur in the neighborhood of gold-bearing quartz lodes. Since the writer has, in the above papers, emphasized the similarity of the bankets to ordinary gold-quartz veins and has laid stress on the importance of the dikes as the agencies to which the mineralization of the bankets is due, others have gradually adopted the same view; for example, Hatch wrote, in 1911, as follows: "The origin of the gold in the Witwatersrand banket has been referred to as one of the greatest riddles of modern times, but evidence is slowly accumulating to prove that the Rand banket is not a fossil 'placer,' but rather that its gold content has an origin similar to that of quartz-veins." (See 'The Auriferous Conglomerates of the Witwatersrand,' *Mining and Scientific Press* (1911).

³⁴⁶C. B. Horwood (1910), *loc. cit.*, pp. 65-92.

³⁴⁷C. B. Horwood (1912), *loc. cit.*, pp. 52-63.

Rand bullion as it occurs in the ore contains approximately 875 parts of gold and 125 parts of silver per thousand. In dealing with the occurrence of gold and carbon in the dikes (*loc. cit.*) the presence also of silver was not discussed; but, in assaying the dike samples for fine gold the differences between the bullion weights and the weights of the fine gold consisted almost entirely of silver.

³⁴⁸Also traces of cobalt.

eralization was brought about. Kemp³⁵² has both constantly and lucidly demonstrated that the igneous rocks are usually responsible both for the contents of veins and also the solutions that conveyed them. Arrhenius³⁵³ has shown that in the fused mass below the earth's solid crust, silicic acid, on account of its smaller density, will be concentrated in the upper portions; while the basic portions of the magma, owing to their greater density, will collect in the lower strata.³⁵⁴ Further, that the fused magma on penetrating into the upper layers would probably be divided into two portions, the first will be the lighter and gaseous, and will contain water and substances soluble in it; the second, or heavier portion, will consist essentially of silicates with a smaller proportion of water. The more fluid portion, richer in water, will be secreted in the upper layers of the crust, and will penetrate into the surrounding sedimentary strata, especially into their fissures,³⁵⁵ and will there deposit their mineral contents. The up-rising, more viscid and sluggish, mass of silicates will congeal. Vogt³⁵⁶ has long recognized that magmas consist of an upper layer of aqueous gas and a lower one composed of a silicate magma; and he strongly emphasizes this relation. He is perhaps the greatest exponent of the part played by magmatic agencies, or rather by what he aptly terms 'eruptive after-action.' In association with the auriferous conglomerates of the Rand there is abundant intrusive basic igneous rock of diabase type that contains gold, silver, pyrite, and carbon.³⁵⁷ These were de-

posited in the bankets during one and the same period, as is evident from their close association and intergrowth, to which attention has already been called. It has been shown that the traces of iridosmine, and other metals of the platinum group, with which the gold is associated, were probably extracted from neighboring dikes under pneumatolytic conditions;³⁵⁸ that the pyrite of the 'pebbles' was almost certainly deposited under high temperature and pressure; and it has, also, been demonstrated that the carbon was either in a gaseous condition or a mobile liquid at the time of its introduction, and so doubtless existed under similar conditions.³⁵⁹

Order of Ascending Magmas

It is necessary to bear in mind the order in which the various up-rising portions of the magma doubtless ascended. Firstly, there would be the more fluid portion, liquid or gaseous, probably the latter, in a mobile active state, which penetrated the bankets and there deposited the main portion of its mineral contents.³⁶⁰ Then followed the viscid silicious

carbon of a typical, decomposed, diabase, longitudinal, or strike dike from the surface down to a vertical depth of over 2000 ft.; together with complete analyses of dikes in the North Randfontein and Rietfontein mines; and gold assays of the latter will be found in Appendices I, II, and III (see also C. B. Horwood (1910), *op. cit.*, p. 77 *et seq.*)

A. R. Sawyer refers to the influence of dikes on the gold contents of the auriferous bankets of the Rand in a paper entitled, 'The New Rand Gold-field,' (*Trans. Inst. Min. Eng.*, Vol. 44 (1912), part I), in which he ascribes the gold to the influence of the basic dikes. He is prospecting a large area for the main Reef series near the junction of the Vaal and Witje rivers, in the Orange Free State some 50 miles south of the Rand, by means of deep bore-holes. These have intersected 15 basic dikes or igneous sheets; and he has had assays made of them for gold; and found that they all contained gold, the amounts varying up to 1¼ dwt. per ton.

³⁵²C. B. Horwood (1912), *op. cit.*

³⁵³C. B. Horwood (1910), *op. cit.*

³⁵⁴The writer has laid stress on the part played by magmatic vapors in the mineralization of the bankets, for example, when discussing the genesis of the carbon in the bankets (*loc. cit.*, 1910, p. 86), he stated: "The study of the carbon in those mines of the Rand where it is most typically developed certainly shows that its occurrence is closely associated with that of the pyrite and gold and indicates a close relationship between its presence and that of neighboring igneous rocks, which have, in the foregoing pages been shown to contain carbon. It is difficult to account for the way the carbon occurs in tiny spheroids scattered through the matrix in Rand bankets other than that it was deposited from gaseous or very mobile liquid hydrocarbons, in a similar manner to that of the carbon-mineral at the Mary mine as described by Kemp, before the final cementation and induration of the bankets by the deposition of secondary silica; and, taken in conjunction with the known facts of its occurrence in other parts of the world, it is perfectly reasonable to attribute its origin to magmatic vapors or solutions derived from the neighboring basic igneous intrusions before their final solidification." Again when dealing with the occurrence, analysis and genesis of iridosmine in the bankets (1912, *loc. cit.*, p. 63) he pointed out that R. B. Young had called attention to the appreciable amount of tourmaline, of undoubtedly secondary origin, in the Rand bankets and its close association with the gold; and to the occasional occurrence of tourmaline veins in the bankets and to the fact that tourmaline sometimes replaces portions of the quartzites and bankets. He remarked that Young did not seem to have realized the full significance of these facts as strongly suggestive of pneumatolytic action; and he would now add that they also fur-

³⁵²'The Role of the Igneous Rocks in the Formation of Veins,' by J. F. Kemp, in 'The Genesis of Ore Deposits,' 2nd Ed. (1902), pp. 681-709. See also 'A Consideration of Igneous Rocks and their Segregation or Differentiation as Related to the Occurrence of Ores,' by J. E. Spurr, *Trans. Amer. Inst. Min. Eng.*, Vol. XXXIII (1903), p. 288 to 340.

³⁵³'Worlds in the Making,' by S. Arrhenius, Harper Bros. (1908), pp. 16 and 20.

³⁵⁴The present writer arrived at a similar conclusion with regard to the division of the magma as a result of his studies of the plutonic complex of the Transvaal Bushveld. Molengraaf had pointed out that the Red Granite occupied the central portion of this area, while other types are confined to the peripheral regions, the basicity of the rocks increasing from the centre to the periphery. In 1905 the present writer called attention to this and suggested that the reason might be due to segregation, according to specific gravities, in the magma before eruption in such a manner that its acidity would increase from below upward. Thus, representatives of the central and earlier stages would be the most acid, while later products would be more basic. The latter would naturally select the marginal portions of the already erupted mass for channels of ascension as offering lines of least resistance; and, thus the final marginal portions would be represented by the most basic varieties of rocks. Further, he suggested that the diamondiferous pipes (which are of an extremely basic character) on the edge of this plutonic complex, to the north-east of Pretoria, represented the final expiring stages of that period of eruptive activity to which this complex is due; and, if this be so, then other pipes of blue ground may occur anywhere around the marginal portions of this plutonic complex. C. B. Horwood (1905), *loc. cit.*, pp. 77 and 78.

³⁵⁵In the case of the Witwatersrand system, some of the conglomerates were selected by these solutions as offering easier channels than fissures.

³⁵⁶'Problems in the Geology of Ore-Deposits,' by J. H. L. Vogt, in 'The Genesis of Ore Deposits,' 2nd ed. (1902), pp. 636-680.

³⁵⁷The results of the systematic sampling for gold and

portion, which deposited the gangue material of the ore in the form of the secondary silica that closed up the interstices of the conglomerates, in a similar way to that in which, by deposition of vein-quartz, normal quartz fissure-veins have become sealed to further mineralizing solutions. Finally, the segregated basic portion of the magma filled and closed the fissures, which are now marked by the presence of this basic intruded rock in the form of dikes. As the dikes cooled eruptive after-action ensued, the liquid and gaseous solutions previously contained in the molten, or more or less viscid, dikes were given off, entered into the main channels of circulation and there precipitated their mineral contents, thus increasing the mineralization of the bankets. A further result of cooling was that the dikes contracted producing fissures within their mass and re-opening minute channels along which solutions under pressure from below continued to ascend and not only deposited mineral matter but doubtless dissolved, re-precipitated, locally concentrated, and rearranged that already resulting from the previous processes.

Evidences of the Deposition Period

The final expiring stages of periods of great eruptive activity such as this can often be detected after the lapse of long geological time.³⁶¹ Today there are lingering traces of such a former period in the deep-seated waters still circulating and associated with certain dikes, or issuing along their junctions.³⁶² In studying these deposits it should al-

nish still further evidence in the replacement of banket and quartzites, of those metasomatic processes which are so usual in quartz veins. In summarizing this paper he referred to pneumatolytic action and concluded that these very rare metals had existed in minute proportions, as primary segregations due to magmatic concentration, in the basic eruptives in these mines; and that by later, or pneumatolytic phases of eruptive activity they were extracted from the dikes by active superheated gases. Still later, hydrothermal action probably played an important rôle in concentrating them in the banket reefs.

³⁶¹Because, for one reason, lines of weakness once established in the earth's crust naturally tend to continue and remain as such.

³⁶²For instance, the West Reef dike at Randfontein and a dike known as the water dike at the Witwatersrand Deep mine are characterized by the large quantities of water with which they are associated. It is a common idea that the water encountered when these dikes are pierced is merely vadose ground-water which has been dammed back on one side of the dikes by the impervious nature of the latter. A little reflection, however, will show that this is not the case, for, in these particular instances, it is well known that in mining, the water follows down as far as the mines have gone, or for well over 2000 ft.; that is to say that when one of these dikes is tapped on a lower level the amount of water issuing from the dike from the level above rapidly becomes appreciably less and soon practically ceases to flow, and this in spite of the fact that in some cases when first encountered it issued under several hundred pounds pressure per square inch and so rapidly that the shaft and levels below were drowned, the pumps being unable to cope with the added volume, and the drives in which the water was encountered had to be dammed up to keep back the water. If one considers, for a moment, a given section of such a dike, either as a section of a retaining wall, or as a pipe full of water in which there are two minute apertures at, say, 1600 and 1800 ft. from its top; the water issuing from both apertures should be about the same, as the difference in head is relatively slight; it

ways be borne in mind that these various processes were not separated by any sharply defined breaks, but that they overlapped each other, and this serves to explain various phenomena (such for example as indications which, at first sight, suggest two periods of gold and pyrite precipitation) otherwise difficult to understand.

Admitting that the source of the pyrite and gold is due directly or indirectly to igneous intrusions, and the magma with which they are in depth connected, then since the auriferous conglomerates of the Rand represent such a huge mineralized deposit, or rather series of deposits, stretching, as proved, for over 60 miles along their strike,³⁶³ these intrusions must have occurred during a period when igneous activity was sufficiently great for extensive and well defined intrusions to have been injected into these beds. The Ventersdorp period³⁶⁴ meets

would take comparatively a very long time to drain the pipe down to the level of the first aperture, and when it was, the water would issue feebly from the lower aperture owing to the great reduction in head. In practice the water issues from the lower level under great pressure and that from the upper level diminishes rapidly. Further, the dryness of the deep-level mines of the Rand is one of their characteristic features in spite of them being mostly connected with the surface through the old workings of the outcrop mines and being therefore under excellent conditions (especially since these conditions prevail throughout miles of adjacent and communicating deep-level mines) to act as huge drains to an enormous catchment area, or terrain. Consequently, at depths of 2000 ft. and over, this theory of ground-water cannot apply unless the water be supposed to descend along the junction of a dike, or through its fractures, in which case the water on an upper level would not rapidly cease to flow when it was tapped on a lower level. If, however, the water be up-rising and of deep-seated origin then, considering the analogy of the pipe, it would overflow at the first aperture encountered, for example, when tapped on the lower level of the mine it would issue there and the stream issuing from the level above would rapidly cease. At Randfontein the writer sometimes detected a smell of sulphuretted hydrogen when large volumes of water had been struck in connection with the West Reef dike in the lower levels of some of the mines, and Henry Hay, formerly manager of the Witwatersrand Deep mine, informed him that he had also sometimes detected a smell of sulphuretted hydrogen from the water issuing from the water dike at the Witwatersrand Deep mine, which supports the opinion that it is of deep-seated origin.

The following is an analysis of the water cut in the West Reef north drive on the 10th level (about 1350 ft. below the surface) at the northern end of the North Randfontein mine.

	Grains per gallon.
Total solids	5.85
Loss on ignition	1.05
Silica	0.91
Iron oxide and alumina.....	0.21
Lime	1.05
Magnesia	0.14
Sulphuric acid (SO ₂)	0.63
Carbon dioxide (CO ₂)	1.82
Chlorine	trace
Hydrogen disulphide	nil

³⁶³If pulled out tandem fashion from their side by side, or twin, positions they would then represent a continuous lode some 120 miles in length.

³⁶⁴The only other period of great eruptive activity comparable to this is that to which one owes the great plutonic series of the Bushveld; still more recently during Karroo times there was a period of eruptive activity during which there was a great outpouring, which was general through-

these conditions. Such intrusions are represented by the longitudinal, or strike, dikes of the Rand³⁶⁵ (which are of diabase type and are highly decomposed and nralitized). The writer has frequently, on previous occasions, pointed out that there is undoubtedly a genetic relationship between these dikes and the Klipriversberg diabase, and that their petrological features, habit, and chemical composition certainly indicate that they have been derived from the same magma.³⁶⁶ The strong development of the Klipriversberg diabase,³⁶⁷ in the Klipriversberg hills (some three miles south of the Rand) in the central portion of the Witwatersrand syncline, where it has an aggregate thickness of some 5000 ft., and also the occurrence in the Bezuidenhout valley of fragmental and volcanic material belonging to the Ventersdorp series, indicate that one at least of the vents from which the volcanic series of this system was erupted was situated in the central portion of what is usually termed the Witwatersrand basin, but which would be more correctly described as the synclinal valley of the Witwatersrand.³⁶⁸ The main structural features of the district, such as are described in the first part of this paper, indicate that the origin of this synclinal valley is due to this, and satisfactorily explain the presence of the numerous longitudinal diabase dikes encountered in the

out the greater part of South Africa, of olivine-dolerite, which is in a very fresh condition today, as is at once apparent when thin sections are examined under the microscope; it is, however, generally admitted that the mineralization of the bankets was long prior to either of these periods.

³⁶⁵The transverse dikes are younger, as is evident from the fact that they have faulted, and in many cases considerably displaced, the longitudinal dikes.

³⁶⁶The writer has pointed out that carbon not only occurs in these dikes; but also, according to Harger, in the Ventersdorp diabase, to which the Klipriversberg amygdaloidal diabase belongs, as he ascribes the origin of another form of carbon, namely the Vaal River diamonds, to this rock. ('The Occurrence of Diamonds in Dwyka Conglomerate and Amygdaloidal Lavas, and the Origin of the Vaal River Diamonds' by H. S. Harger, *Trans. Geol. Soc. So. Af.*, Vol. XII, (1909) pp. 129-158.) The writer also showed that the sheet of amygdaloidal diabase found at a fairly constant horizon (but often split up into several bands) in the Upper Witwatersrand beds, between the Kimberley and Bird Reef series, on the far East Rand is intrusive and is macroscopically, microscopically, and chemically similar to the Klipriversberg amygdaloid, with which it is certainly connected. Also, that an amygdaloid dike occurs in the Saxon gold mine, on the West Rand (see 'The Main Reef Horizon on the Eastern Edge of the Witpoortje Break,' by J. P. Johnson. *Trans. Geol. Soc. So. Af.*, Vol. IX, pp. 17 and 18); and, that Geo. S. Corstorphine had told him of the occurrence of a dike of amygdaloidal diabase, 40 ft. wide, which can be traced for 1200 ft. in the Heidelberg district of the Transvaal. Further, the writer pointed out that there was no scientific reason why a dike should not be amygdaloidal, under given conditions, provided the temperature of the aqueous and other vapors that occasion the vesicular cavities remain above the critical temperature during the solidification of the rock, for then these vapors will exist as such and will not liquefy, although their densities may be greatly increased; hence amygdale-shaped cavities will be formed, which will eventually become wholly or partly filled by the deposition of silica, calcite, chlorite, or other secondary mineral matter. See C. B. Horwood (1905), *loc. cit.*, pp. 35-41; 1910, *loc. cit.*, pp. 39, 42, and 43; and (1910), *loc. cit.*, pp. 76, 77, and 81.

³⁶⁷Which belongs to the Ventersdorp series.

³⁶⁸As pointed out in part I of this paper.

mines of the Rand, as well as several other phenomena.³⁶⁹

Mineralization in the Pilgrim's Rest District

The origin both of the gold and of the mineralization generally in the bedded quartz deposits of the Dolomite, in the Pilgrim's Rest district have already been assigned to the neighboring intrusive igneous sheets and diabase dikes;³⁷⁰ and the writer's own observations in this district amply confirm this view. One basic dike can be traced for 1½ miles. It is considerably mineralized with magnetite, pyrite and a little chalcopyrite, which are apparently primary constituents. Assays of this dike give traces of gold. Concentration of the pyrite and copper pyrite has taken place on the fracture-planes produced by the cooling of the intruded rock; and, where there has been considerable concentration of these minerals, assays will yield up to 1½ dwt. per ton.³⁷¹

³⁶⁹C. B. Horwood, 'Notes and Analyses of Typical Transvaal Rocks,' *loc. cit.*, in which paper the writer pointed out that the strike of the Klipriversberg hills is east and west, that is, parallel to the strike of the Rand bankets; to the longitudinal dikes; and to the main structural faults, suggesting that they mark the site of a fissure of eruption, situated in the central portion of the Witwatersrand syncline. He also called attention to the fact that G. A. F. Molengraaff, in his 'Geology of the Transvaal,' has shown that the basin of the plutonic series of the Bushveld was produced by the sedimentary strata sinking under the weight of the intrusive masses withdrawn from below; and that, consequently the surrounding strata is pierced by numerous dikes and igneous intrusions from the same original magma, and all around the basin the strata dip inward toward a common centre. The present writer then showed that there is considerable analogy between the Bushveld basin and the Witwatersrand syncline; and similarity of origin not only explained the presence of the numerous ancient strike (or longitudinal) diabase dikes, but also, the main structural features of the Witwatersrand, such, for example, as the fact that, along the northern rim of the Witwatersrand syncline the main dikes strike east and west and dip south, while along the western edge of the syncline they strike north and south and dip east, and in each case the direction of their strike and dip corresponds with that of the strata, that is, the strike follows the contours of the syncline and the dip is always toward its main axis, which by analogy with the Bushveld plutonic basin, has evidently sunk under the weight of the igneous masses, in this case Ventersdorp diabase, withdrawn from below.

³⁷⁰'The Geology of Pilgrim's Rest Gold Mining District,' by A. L. Hall. Transvaal Mines Department Geol. Surv., Mem. No. 5 (1910), pp. 138-144. Hall pointed out that these 'reefs' have an essentially quartzose nature and are associated with metallic sulphides, notably iron pyrite. Also that a higher gold content and abundance of pyrite, decomposed or fresh, frequently go together, and that the more earthy (richer in hydrated iron ore) or spongy the ore the greater its value, pointing to the introduction of the gold being directly dependent on the presence of pyrite; the gold having been introduced by circulating underground waters carrying gold, iron, and silica in solution. He also called attention to the influence of shales on the gold deposition, several 'reefs' being situated in close proximity to horizons where shaley beds are associated with calcareous, or other more permeable, strata.

³⁷¹W. H. Randall, managing director of the South-East Africa Co., Ltd., gave the writer the particulars of this dike which is known as the Malidike (*mali* is the native word for money). It pierces the Black reef and Dolomite series and outcrops on the farm Graskop, just southeast of Pilgrim's Rest. Near the surface it is reddish-brown and much decomposed; in depth it is hard and is dark-green in color, and much fractured. In the decomposed zone the

The officials of the Cape of Good Hope Geological Survey have shown that the Ventersdorp diabase is intrusive in the Black Reef and Dolomite formations of the Vryburg district.³⁷² Carbon not only occurs in the dikes and in the auriferous bankets of the Rand, but also in the Black Reef banket; and in at least one of the bedded quartz veins of the Dolomite in the Pilgrim's Rest district. Metasomatic pyrite 'pebbles' are found not only in the Rand banket, but also in the Black Reef banket;³⁷³ and gold is asso-

ciated with pyrite in the interbedded ore-sheets in the Dolomite of the Pilgrim's Rest and Lydenburg districts.

Genesis of the Gold

Thus it would seem that the genesis of the gold (and of the pyrite, carbon, and other minerals with which the gold is associated) of the Witwatersrand banket, and of the Black Reef conglomerate in the Southern Transvaal, and of the bedded quartz veins in the Dolomite and also in the Black Reef formation of the Northern Transvaal, can be satisfactorily explained on the assumption of one period of mineralization and that the gold was introduced into the Rand conglomerates after, or during, the period when the dolomites were being laid down. Thus as previously foreshadowed³⁷⁴ the immense wealth of this richest of all goldfields is apparently a product of the period of eruptive activity to which the Ventersdorp series is due: the mineralization representing some of the final expiring stages of volcanic and eruptive activity characteristic of that period: the diabase dikes (genetically related to the amygdaloidal diabase of the Klipriversberg) and their underlying magma being responsible, directly or indirectly, for the gold.

magnetite remains unaltered, while the pyrite is converted into limonite; the decomposition of the chalcopryite being manifested by an occasional greenish stain.

For about a mile the surface of the dike has been extensively worked by sluicing, some of the workings being of great size and as much as 70 to 80 ft. deep. Between 1870 and 1880 considerable quantities of gold are said to have been won from a small stream known as Digger's creek, running below and parallel with, the dike. Large piles of debris and boulders and numerous channels cut to divert the stream from its original course testify to the activities of the old diggers, who, after working the gold in the creek, turned their attention to the outcrop of the dike itself.

Within recent years quartz veins have been located, both within the dike and on its contacts, below the level to which the outcrop of the dike had been stripped by sluicing. A small 5-stamp mill and cyanide plant has been erected; running intermittently it has produced some £12,000 worth of bullion. An analysis of an average sample of the dike made up from samples taken at regular intervals over a section of 120 ft. gave 15½ dwt. gold and 6½ dwt. silver per ton; besides iron, it revealed the presence of a small quantity of copper, bismuth, and a trace of nickel.

Concentration tests have proved that the gold is present in an extremely fine condition. Well defined lenses of vein-matter are sometimes found, on the contacts of the dike with the sedimentary beds, varying from a few inches up to 3 or 4 ft. thick and some hundreds of feet long. The veins sometimes leave the contacts and continue in the dike with sinuous courses. Profitable ore has been found on both sides of, and also within, the dike. The gold contents vary greatly within short distances, samples taken only 2½ ft. apart often giving very different results. High assays are more often obtained where the ore is colored a bright red with iron oxides; and below the permanent water-level the undecomposed pyrite gives good gold assays. The 'reefs' are not continuous throughout the length of the dike, either within it or along the contacts; on the latter there is often only a few inches of selvage matter. Within the dike there may be a regular stockwork of quartz leaders, but no defined vein; or there may be considerable bodies of white, fractured, barren-looking quartz which gives traces of gold; or sometimes a well defined lode with good gold contents. Rundall ascribes the origin of these 'reefs' to the dike intrusion and subsequent contraction, and to the circulation along the fractures thus produced of deep-seated mineralizing solutions.

³⁷²A. L. du Toit, 'Report of the Geol. Com. of the Cape of Good Hope' (1905); also A. W. Rogers in the 'Annual Report of the Geol. Com. of the Cape of Good Hope for 1906'; and also 'Geology of a Part of Bechuanaland West of Vryburg,' by George G. Holmes, *Trans. Geol. Soc. So. Af.*, Vol. VII (1905), p. 131. The present writer has recently shown that the Ventersdorp diabase is also intrusive into the Black Reef series in the Transvaal. 'Note on the Relationship between the Black Reef Formation and the Ventersdorp Diabase,' by C. B. Horwood, *Trans. Geol. Soc. So. Af.*, Vol. XV (1912), pp. 77 to 80.

³⁷³C. B. Horwood (1910), *loc. cit.*, p. 83, where he stated that Andrew Crosse informed him that the ore, which is of a pyritic nature, from the Theta reef from the Lisbon-Berlyn mine, near Pilgrim's Rest, contains carbon; and gave the result of a complete analysis, made by Crosse of a typical sample of rich ore from this mine which gave 1.28% of carbon; and 16 dwt. of gold and 114 dwt. of silver per ton.

At the same time he stated that Crosse had called his attention to the fact that "carbon exists in very appreciable amount in the Black Reef banket in the Machavie mine, between Klerksdorp and Potchefstroom." At this mine the banket is of a very pyritic nature and contains numerous 'pebbles' of pyrite. Crosse further informed him "that an appreciable quantity of carbonaceous or graphitic material is found in the highly pyritic silicious ore from the Mount Morgan mine on Moodies, near Barberton." Iridosmine also occurs in the auriferous banket of the Rand, and in that of the Black Reef formation at Klerksdorp. C. B. Horwood (1912), *op. cit.*, pp. 52 and 53.

N. B.—The Theta reef is near the top of the Dolomite formation, near its contact with the overlying shales of the Pretoria series.

³⁷⁴Notes and Analyses of Typical Transvaal Rocks,' by C. B. Horwood, *Trans. Geol. Soc. So. Af.*, Vol. XIII (1910), p. 43.

APPENDIX No. 1

CARBON IN THE WEST REEF DIKE, NORTH RANDFONTEIN MINE
Average dip of dike, 72°; average width of dike, 5½ feet.

Level.	Distance apart measured along dip of dike (feet)	Vertical distance below collar of shaft (feet)...	Fine gold present.		Carbon present, percentage	Remarks.
			Dwt. per ton.....	Percentage		
2nd	200 from surface	190	Nil	Nil	0.70	Soft decomposed specimen, light gray in color. The sample for gold was taken over the central 8 in. of the dike.
3rd	126	307	0.55	0.00009	0.12	Fissile, schistose structure, considerably decomposed; light gray slate color. The sample for fine gold was taken over the central 6 in. of the dike.
4th	205	407	0.73	0.00013	Trace	Soft decomposed specimen; light gray in color. The sample for gold was taken over the central 18 in. of the dike.
5th	106	508	1.29	0.00022	0.22	Fairly fresh; somewhat schistose structure. A good deal of mica observable in specimen. The sample for fine gold was taken over the central 12 in. of the dike.
6th	155	660	0.04	0.000007	0.08	Fairly fresh specimen; more so than from fifth level. A good deal of mica observable in specimen. The sample for gold was taken over the central 12 in. of the dike.
7th	203	859	0.80	0.00014	0.08	Fresh specimen; a little copper pyrite is present. The sample for fine gold was taken over the central 12 in. of the dike.
8th	201	1058	Trace	0.22	See analysis in column 1 in Appendix No. 2. The sample for gold was taken over the central 12 in. of the dike.
9th	158	1207	0.85	0.00015	0.02	Good fresh specimen. The sample for fine gold was taken over the central 12 in. of the dike.
10th	158	1357	Trace	0.04	Fresh specimen; but a little weathered on the surface. The sample for gold was taken over the central 12 in. of the dike.
11th	156	1504	1.46	0.00025	0.05	Fresh specimen. The sample for fine gold was taken over the central 12 in. of the dike.
12th	158	1653	2.35	0.00040	Trace	Fresh, very close-grained specimen. The sample for gold was taken over the central 24 in. of the dike.
13th	157	1803	0.25	0.00004	0.06	Fresh specimen; weathered on one surface. The sample for gold was taken over the central 24 in. of the dike.
14th	154	1950	0.30	0.00005	0.03	Fresh specimen, very close-grained. The sample for gold was taken over the central 12 in. of the dike.
15th	149	2090	3.00	0.00051	0.04	See analysis in column II, in Appendix No. 2. The sample for gold was taken over about the central 12 in. of the dike.

In the above, trace = under 0.01% for carbon; and 0.1 dwt. or under in the case of fine gold.

The samples for both gold and carbon were taken in the cross-cuts (with the exception of that from the 3rd level, which was taken in the West Reef south drive) over the central portion of the dike; the samples for the carbon analyses were in each case taken over the central 12 inches.

III. The big southern diabase dike from the eastern section of the Rietfontein mines.² There the dike is about 230 ft. thick and the sample analyzed was from the central portion, from 114 ft. inside the dike. The diameter of the core was 15/16 inch. The rock was of a light grayish-green color, close-grained and compact, but rather soft, being scratched with a knife. It looked considerably decomposed, and was covered with thin streaks and blotches of some white substance, which evidently represented some decomposition product, which effervesced strongly with dilute hydrochloric acid and was probably calcite; and it will be noticed that the analysis reveals the presence of 10% lime. It will also be observed that the analysis shows 0.03%

exist throughout the mines of the Rand; and that all the cyanide solutions which he has analyzed contained cobalt, copper, and nickel, there being generally a little more cobalt than copper; and, of course, less nickel than either. He discovered arsenide of cobalt from the Driefontein and Angelo mines by noticing a heavy substance come off a Wilfley table on the outer edge of the rest of the concentrate, which by analysis he found was cobalt arsenide.

²From bore-hole No. 67 (No. III shaft, 9th level, south cross-cut). The assays in Appendix No. 3 are from this same dike.

carbon. Another sample³ of this same dike from the eastern section of the mines was also analyzed for carbon and found to contain 0.2%. A further sample of dike⁴ from the central section of the mines showed a trace of carbon. It is worthy of note that the two samples from the eastern section contain more carbon than that from the central section, and it is in the eastern section of the mines that carbon is most abundant and the gold contents of the ore are highest. In this connection it may also be mentioned that the presence of carbon in the North Randfontein mine, where the West Reef dike is well developed, is a far more characteristic feature than it is in the Robinson-Randfontein mine, where this dike is only very poorly developed; and the former mine is richer in gold than the latter.

³From bore-hole No. 65, No. III shaft, 9th level; 4 east stope (see details of same bore-hole in appendix No. 3). The bore-hole passed through 190 ft. of dike and the core (15/16 in. diam.) used for the analysis was from a distance of 127 ft. inside the dike.

⁴From bore-hole No. 17, No. V shaft, 5th level, north cross-cut. The drill passed through 355 ft. of dike and the core selected for analysis was from a distance within the dike of 170 feet.

Coke-Making in China

The Chinese have always made a good deal of coke, as throughout the whole country the coal is commonly rather friable, and the loss by dusting and spilling in the course of transport over long distances would be prohibitive, while hard coke will endure handling. In some cases the coke is made into heaps which are covered up and burned, much as in charcoal-making in Europe. A more elaborate form of Chinese coke-ovens is shown in the illustrations. These ovens are filled with small coal, which is carried to the oven in baskets, having previously been washed in wicker baskets by hand. The charge consists of about 24 tons of two sizes of coal in layers; dust and about 1-in. pieces. The ovens are 14 ft. in diameter on top, 7 ft. on the bottom, and 6 ft. deep in the centre. The top 3 ft. of the sides is vertical, and the lower 3 ft. slopes toward the centre. There are 18 small draft holes in the sides of the oven and a larger hole on one side near the bottom. The lower half of the oven is beneath the level of the ground. Each layer is tamped by coolies wearing shoes having thick wooden soles. One charge makes about 12 tons of coke. The bottom three feet of the coke is of poor quality, but the rest is fair. After burning, the coke is quenched by water carried in buckets. It takes about four days to fill, two weeks to burn, and two days to cool an oven. According to figures given by Y. T. Woo in the *Transactions* of the American Institute of Mining Engineers for 1906, the coal used for coking at Tongshan is worth \$4.50 silver at the oven and the coke sells for \$18 to \$20 silver per ton, affording a good profit. The Tongshan coke made in this way contained 15.2% ash and 0.97% sulphur. Washing the coal and filling and discharging the ovens is done by contract labor, the laborers earning about 20c. silver each per day. More recently a washing plant and modern coke ovens have been built at Tongshan. The lower illustration shows one of two banks of Otto ovens at the Pingsiang colliery in Kiangsi. Here also the coal, which contains 25 to 30% ash, is washed before coking, and then yields a coke almost free from sulphur and low enough in ash to serve excellently in the iron blast-furnaces operated by the same company at Hankow. Two grades are made, foundry and smelting coke. The first contains: fixed carbon, 87.941%; ash, 10.94; and sulphur, 0.506. The corresponding percentages in the smelting of coke are: 88.06, 11.10, and 0.618 respectively. Considerable quantities of this coke comes to the Pacific coast states, as does also iron made with it. It has recently been proposed to remove this coking plant to the vicinity of the blast-furnaces, so that the coke oven gas can be mixed with the furnace gases for power production.

Revision of the Mining Law—A Critique

By ROBERT M. SEARLS

In the *Mining and Scientific Press* of October 18, 1913, there appears an article on 'Revision of the Mining Law—a Protest,'* which calls for comment. Largely because my conclusions upon the subject of mining-law revision coincide with those of the author of that article, I am moved to express my dissent from many of the premises which he assumes as a basis for his conclusions, and to offer what seem to me to be the cogent reasons why the fundamental principles of the federal mining law should not be changed, even if a few minor modifications are admittedly desirable.

Department Regulations

At the outset, the severe condemnation of Department officials indulged in by the writer of that article is surely unwarranted. There have been few abler men in the presidential cabinets of the past few years than those who have headed the departments of the Interior and Agriculture. If in the administration of the public land laws they have woven into the rules of procedure, which were entirely within their jurisdiction to make, somewhat onerous requirements as to what the miner must prove before he is entitled to his grant in fee simple from the government, it must be remembered that these officers are charged with the duty of protecting the government from imposters. There have been so many cases where speculators, 'land-sharks,' and unscrupulous public-service corporations have acquired valuable power-sites, timber lands, and a practical monopoly of water rights, under the guise of mineral patents, where no commercially valuable mineral in fact existed, that the government officers have not unjustifiably come to require a higher degree of proof than was formerly exacted. The honest miner, confident of the justice of his claim for a patent, naturally finds the departmental 'red tape' irksome to unwind; but the black sheep cannot always be segregated from the white, and he must bear his share of the burden of protecting all the people from imposition by an unscrupulous few.

Miners' Customs

The writer of the 'Protest' next suggests that miners' rules and customs afford ample protection against 'land-grabbers.' In the first place, under what theory should the disposition of the public domain—the domain of all the people of the United States—be left to the protection of miners' rules of the locality in which it happens to be situated? The federal statutes, it is true, recognize rules and customs of the mining districts, but surely Congress never intended to look to those districts to protect the public domain from wholesale land-grabs, or to deprive itself of the power to vest in the proper government officials the administrative power over the disposition of that domain under the general

laws. In the second place, miners' rules and customs have so far fallen into decadence that in most instances they have become entirely obsolete. They have been supplanted by state legislation, supplemental to the federal law, which in its more important features is practically uniform throughout the mining states. This state legislation serves to cover the local requirements for special rules in 'blanket lode' districts, and in a measure to reinforce the federal law as to assessment work. I shall speak further of the need of reform in this last subject later. If the federal law had nothing more to supplement it than the district regulations, in most places obsolete, the call for reform might have more justification.

Locators' Title

Again, the writer of the 'Protest' states that the mining laws confer a right of exclusive occupancy upon a locator for the purpose of discovering minerals. One infers from his statement that this occupancy is for all time—or at least so long as the claim is held as a mere location and no patent is applied for. Let us see what the law says. Section 2319, Revised Statutes, reads as follows:

"All valuable mineral deposits in lands belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase, and the lands in which they are found to occupation and purchase by citizens of the United States and those who have declared their intention to become such, under regulations prescribed by law, and according to the local customs or rules of miners in the several mining districts, so far as the same are applicable and not inconsistent with the laws of the United States."

Discovery

From the above section it will be seen that only the lands in which valuable minerals are found are open to occupation and purchase. In construing this, the courts have indeed given expression to the doctrine of *pedis possessio*, that is, that a miner who has taken the preliminary steps to locate a claim, and is proceeding with due diligence to make a discovery of mineral thereon, will be protected in his possessory right so long as he continues in his discovery work. This rule, made necessary to prevent physical conflicts, has been crystallized into a law in some states and a definite period allowed for discovery work. But nowhere does it appear that mere occupancy confers a locator's title, or that Congress ever intended that it should. The necessity of a discovery is everywhere upheld. In the case of oil placers, the California Supreme Court has well stated the rule in *Miller v. Chrisman*, 140 Cal., 440, 447, where Justice Henshaw said:

"To constitute a discovery, the law requires something more than conjecture, hope, or even indications. The geological formation of the country may be such as scientific research and practical experience have shown to be likely to yield oil in paying quantities. Taken with this, there may be other surface indications, such as seepage of oil. All these things combined may be sufficient to justify the

*Written by Russell L. Dunn for the *Mining and Engineering World*.

expectation and hope that, upon driving a well to sufficient depth, oil may be discovered, but one and all they do not in and of themselves amount to a discovery."

But the Court continues a little later:

"One who thus in good faith makes his location, remains in possession, and with due diligence prosecutes his work toward a discovery, is fully protected against all forms of forcible, fraudulent, surreptitious, or clandestine entries and intrusions upon his possession."

By the above rule, which is very different from that stated by the writer of the 'Protest,' the bona fide miner is protected during his actual possession and continues diligent search for mineral prior to discovery, while the Government is protected against 'paper locators' and persons who seek to acquire tracts of public domain for purely speculative purposes. No location title can be perfected until a discovery is made.

Rental System

Another assertion advanced is that the exaction of rentals for mining ground by the Government would constitute the imposition of an "unconstitutional federal tax" on the miner. This is legal nonsense. For a long period prior to adoption of the present mining laws, the federal government did lease the public mineral lands and no question of constitutionality was ever raised. As sole proprietor of the public domain, the federal government can impose such restrictions as it sees fit upon its disposal. The only question involved is one of policy. Some serious objections to the leasing system from the standpoint of policy may exist. But as a matter of law, there can be no doubt of the constitutional power of Congress to change its public-land policy in the manner suggested if it sees fit.

Extralateral Rights

One more erroneous statement made by the writer of the 'Protest' is as follows: "If the people consider that it is to their best interests that lode claims in their district should not have extralateral rights, they may make rules and regulations of lode-mining claims which limit them to their side boundary lines." Section 2322, Revised Statutes, guarantees to the locator the right to follow his vein on its dip and within the boundaries of parallel end-line planes, although such vein, lode, or ledge may so far depart from a perpendicular in its course downward as to extend outside the vertical side-lines of such surface location. Any district regulation abolishing the extralateral right would be in contravention of the above statute and consequently void. What the writer was probably thinking of was the situation which arose in the 'blanket lode' districts in Colorado, where the dip of the veins was nearly horizontal, and the locator of the apex would acquire a segment of vein running underneath the whole district. Although the courts held that if the locator could prove his apex he would be entitled to his extralateral right, in nearly every case the matter was settled practically by the jury's refusal to find any apex. With this tacit recognition of the situation, these districts were worked for the most part with vertical boundary claims, and no dispute has arisen for many years.

Timber Cutting

Finally, the writer of the 'Protest' asserts that officers of the Department of Agriculture have made it a rule that miners must buy timber of them for mining purposes, and that they may buy only what these officers choose to sell, although the statutes grant free timber for mining purposes. This statement is not borne out by the rules or practice of the Department. Miners are allowed to take free timber from their own claims to use for mining purposes on such claims. They are prohibited from taking timber from public land outside of their claims for use on such claims or from selling or otherwise disposing of for commercial purposes timber on their claims. All of which regulations are in entire harmony with the federal law.

With this criticism of various legal fallacies appearing in the above-mentioned article, which, if uncontroverted, might lead one to suppose that the opposition to revision of the mining laws has no sounder foundation, permit me to state briefly the objections to such revision which are being advanced by its leading opponents at the present day.

Confusion of Titles

First—The time for such revision, if it ever existed, has gone by. A fundamental change in the law at this time can only result in unutterable confusion in mining titles throughout the Western states. Rights which have vested under the apex law would be thrown into constant conflict with rights which would be claimed under a vertical-boundary leasing system. Titles which have been finally settled after years of litigation would again be subject to scrutiny, and the always difficult burden of proving his apex would again have to be taken up by the extralateral claimant. Forty years of decisions have served to mold the American mining law to fit the actual physical conditions which have arisen. It is comparatively seldom now that a case involving interpretation of the federal law comes into the appellate courts. An occasional conflict—not many—arises between rival claimants to the underground segment of a vein, but it usually stops with the finding of facts in the trial court. The districts in which the apex law worked a real hardship in earlier days have settled their mining titles to their own satisfaction. The requirement of discovery and improvements sufficient to act as a guarantee of good faith, properly enforced by the land department prior to granting patents, protects the Government against impostors. Where a change to a leasing system might open to prospecting a few lode claims which are illegally held under color of a locator's title, it would cause dismay to thousands of miners who have in good faith located and worked claims for years past, not always profitably, but always with hope of ultimate success. Many of them would be put to the expense of litigation to defend what is now conceded to be theirs. I have been speaking more particularly of lode claims. The same thing is true of placers, and in a greater measure in some respects. The present locator of a placer subdivision, not having his boundaries marked where he is on surveyed land, would be un-

der the necessity of submitting to the leasing system and paying rental to the Government or being constantly put to the necessity of proving his location against a prospector armed with a government lease. Slight modifications in the present law can remedy the existing evils.

Economic Considerations

Second—To substitute the judgment of the average government surveyor, passing hurriedly over large tracts of public land, for the judgment of the prospector who painstakingly examines each subdivision for the mineral he seeks, would not help, but hinder, the mining industry. An arbitrary classification of public lands will be a detriment to its proper economic development. There is an old saying in the mining country that "gold is where you can find it." And it is usually necessary to engage in considerable prospecting work to find even indications of metal. Only the prospector, actuated by economic motives, will devote the necessary time, labor, and money to a proper determination of the character of the land. Such a fundamental change in the law as will eliminate the requirement of a "discovery" as a basis for determination of mineral character, and substitute therefor the judgment of the average government surveyor, however conscientious he may be, is contrary to the best interests of the industry it is sought to develop and not to retard. The needs of posterity have been amply cared for by the extensive withdrawals already made of oil, coal, and timber lands. The "ploughed furrows" and "shotgun patrols" in the oilfields, to which the editor of the *Press* recently alluded, can be obviated by the requirement of permanent boundary monuments in the case of placers as well as lodes, and a proper policing of the oilfields.

Suggested Modifications

In other words, the opponents to the proposed mining legislation believe that the need is not for new and radical changes in our mining laws, involving the substitution of bureaucratic classifications and regulations for economic principles, but rather the enforcement of the spirit of the existing laws, with one or two modifications necessary to make the intent clearer and its enforcement easier.

I have already indicated that the requirement for permanent boundary markings should be one of these modifications. Mexican requirements in this respect could be profitably followed. The other greatest need is for a better assessment-work statute. The suggested payment of annual rentals to the Government in lieu of annual labor might swell the public treasury, but it will not help the development of the land. A man should not be allowed to hold a claim for over a year after location without working it, as the "calendar year" law now permits. The year in which the location is made should be included as a year in which labor must be performed. Some means of supervision should be devised to insure its being performed in fact, and not merely a formal proof of labor recorded.

Conclusion

In conclusion, I believe that the opinion of a ma-

jority of the men who know and understand mining conditions and the needs of the mining country is against a fundamental revision of our mining laws. The original policy of the Government was to encourage the maximum development of our mineral resources along economic lines, subject to just sufficient regulation to insure good faith and honest development. The magnificent growth of our mineral-producing states is a tribute to the wisdom of this general policy. The evils which have been attendant upon its administration have been due to a subversion of the spirit of the law, not to errors in the policy on which the law was based. At this late date, after forty years of judicial interpretation have firmly established the principles of this mining code as applied to actual conditions, let us not change its fundamental basis and have two systems of law to administer. Let us rather seek with the aid of minor modifications, if necessary, to enforce the spirit of the present law to the wisdom of which the prosperity of our mining states so strongly bears witness.

Safety in Tunneling

At times even experienced men believe the roof of a tunnel to be sound, when suddenly and without warning a large block crashes down. This is generally regarded as an accidental occurrence; yet even the danger from such a block in many cases might have been discovered in time if there had been a systematic and regular examination of the roof of the tunnel. For this reason a miner should form the habit of examining the roof as he passes through and test all places that appear to be unsound.

It should be said in this connection that sounding a roof is not a proper way of determining its safety; there are numerous cases on record where the roof gave a satisfactory sound and appeared solid even to experienced men, but in which a block or boulder was actually loose. A better method of testing the roof, which is used by many large mining companies and is recommended by the Bureau of Mines, is to strike it with a pick or heavy stick, at the same time touching the doubtful piece with the free hand. If any vibration is felt, the rock is unsafe and should be taken down or supported at once. If the rock is too high to reach with the hand, a stick should be held against the doubtful piece while it is being struck, and if it is loose the vibration can be felt through the stick.—*Miners Circular, Bureau of Mines.*

Pennsylvania, Ohio, Illinois, and West Virginia are credited with over 40% of the total mineral production of the United States. Pennsylvania outranks all other states, producing nearly 25% of the total, West Virginia comes second, Illinois third, and Ohio fourth. California, with no standing as a producer of pig iron, iron ore, or coal, stands fifth in rank among the states, owing to its heavy production of gold and petroleum.

Dividends paid by mining companies in Western Australia, during the first nine months of 1913, amounted to \$3,030,000.

Dredging at Natoma, California

By M. W. VON BERNEWITZ

In Sacramento county, the work of the Natomas Consolidated of California is well known, and much of its operations has been dealt with in the technical press from time to time, so the following notes cover certain details not usually considered, though of great importance.

Scattered over a length of about twelve miles, the Company has 10 large dredges at work on the south

NATOMA NO. 7 DIGGING INTO THE PAY.

bank of the American river. Some time before the visitor to Natoma reaches there, are seen large piles of tailing consisting of gravel of all sizes, and here and there among them is the gantry of some dredge just visible above the waste. At Fair Oaks is a large rock-crushing plant,* producing several sizes of stone from the tailing, which is shipped to all parts of the state for ballast and road construction. The crushing plant which the Company has maintained at Natoma is temporarily shut down. The ground attacked by the dredges differs considerably from time to time, but during one month's operation the performance of the dredges was as follows:

	DREDGES									
	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
Bucket capacity, cubic feet.....	13.5	8.5	8.5	13.5	9	9	9	15	15	15
Height of bank being dredged:										
Above water, feet.....	4	3	6	2	12	6	20	10	3	16
Below water, feet.....	16	23	20	18	44	54	42	53	58	21
Daily operating time, hours.....	19	20	19	21	21	21	20	19	20.5	19
Gravel dredged, cubic yards...	232,014	232,644	124,440	205,274	159,294	150,553	170,690	142,529	238,004	253,376
Power consumed, kilowatts.....	221,440	143,520	137,600	192,600	238,800	219,600	272,000	346,800	362,400	282,000

It will be seen that the banks being dredged vary from 20 to 63 ft. in height, but the operating time is fairly even throughout. The gravel handled by No.

*Described in *Mining and Scientific Press*, November 6, 1909.

1. 2. 3. 6. 7. 8. 9. and 10 boats was for October; by No. 4 during September, and by No. 5 during May. the latter having capsized during that period, but has since been righted, overhauled, and is in full working condition again. A study of the yardage against the power consumed, the latter being in the same months as given, shows at once the physical character of the gravel being attacked. In the case of No. 2 the power used is only 0.62 kw., against 2.4 kw. per cubic yard by No. 8 dredge.

Boat No. 10

A day's study of No. 10 boat, the hull of which is of steel, under full operating conditions, shows what a powerful machine it is. On the ladder is a bucket-line of 82, 15-cu. ft. buckets, each weighing 4200 lb. This is driven by a 400-hp. General Electric motor, belted to a countershaft by a 32-in. leather belt, in turn driving the gear of the top tumbler by a 32-in. rubber belt. The 9-ft. revolving screen is driven by

STACKER OF NATOMA NO. 8 DURING RECONSTRUCTION.

a 75-hp. motor of the same make. For keeping the buckets against the gravel bank or stepping ahead are two steel-plate, box-construction spuds, weighing 45 tons each. A 50-hp. motor drives the 42-in. rubber stacker-belt, being placed right at the discharge end; while a 50-hp. variable-speed motor drives the winches for lateral movement of the boat. The following centrifugal pumps are used: a 14-in. high-pressure for the revolving screen; a 14-in. low-pressure for the gold-saving tables; a 12-in. for two giants which wash down the bank, and a 6-in. for general work. The dredge complete weighs 750 tons. At the time of my visit the dredge-men were engaged in building a dam of mud and gravel at the back of the boat, in order to prevent water flowing away through the tailing, and to deepen the pond, as it was found that bedrock was rising rather rapidly. This work takes time and is done by skillful manipulation of the buckets and stacker.

At Natoma, a large and complete machine-shop is

maintained, where new buckets are assembled and old ones repaired, tumblers are relined, and all necessary repairs are effected for the 10 dredges. During September, the Company's boats yielded gold worth \$198,621, the profit being \$94,864.

Mining and Milling at the Vulture Property

By W. M. Wood

The property of the Vulture Mines Co. is about 15 miles southwest of Wickenburg, Arizona. The holdings consist of twenty claims, a well equipped mill, and all the necessary paraphernalia for operating a modern mine. About 500 people make their homes at the mines, and approximately 200 men are on the payroll of the Company. The original location was made about 1863 by John Wickenburg, who founded the town of Wickenburg and gave it his name. Mr. Wickenburg and others mined the rich oxidized ore from near the surface and hauled it to mills on the Hassayampa river where the gold was extracted to the satisfaction and enrichment of the owners. This kind of work was continued until 1880.

The Mill

In 1881 an 80-stamp mill was built on the property by George B. Treadwell and associates. The stamps weighed about 750 lb. each. All the machinery for this mill was hauled to the mine from Ehrenburg, on the Colorado river, a distance of about 100 miles. The treatment was by amalgamation. A large tonnage of tailing was produced, about 30,000 tons of which was leached by a succeeding management at a supposedly good profit. The present management acquired the property in September 1908. Twenty stamps in the old mill were put into commission and run for about a year, in order to arrive at definite conclusions as to the proper treatment for the ore and the kind of mill to erect. The new mill was erected in 1910 and placed in operation in September of that year, the use of the old mill being totally discontinued. The new mill consists of twenty stamps of 1650 lb. each, with a capacity of 100 tons per 24 hours when crushing to 40 mesh. Amalgamation is effected inside the mortars, the ore being crushed in a cyanide solution. Both sand and slime are concentrated, 4 Wilfley and 3 Deister tables being used. The tailing from the tables is sent to the cyanide tanks, consisting of 4 large Dorr thickeners. The gold is precipitated by the Merrill zinc-dust process. The concentrate is shipped to the El Paso smelter for final treatment. The regular mill feed will average about \$20 per ton in gold, and the saving is effected approximately as follows: amalgamation, 60%; concentration, 20%, and cyanidation, 20%. The greater portion of the fuel used is crude oil and distillate. Six-ton motor-trucks are used to haul the fuel oils, and are loaded with concentrate on the return trip. Haulage expense has been reduced about 50% by the use of the truck in place of teams. The trucks use distillate for power. The main working shaft is 750 ft. deep on a 40° incline. It is a single compartment with two skip tracks. Because of faulting of the orebody, the present workings are about 400 ft. east of the main working shaft. There are about three miles of underground work. The main working shaft is timbered throughout with 8 by 8-in.

square sets, being 5½ by 10 ft. in the clear. The ground is good and easily held, no trouble having been experienced in the shaft for several years. The hoisting equipment consists of an Ottumwa double-drum steam hoist, handling skips of one-ton capacity, which dump automatically into bins. The ore is then trammed by hand to the crusher bins, about 150 ft. distant. From there it goes through a No. 5 Gates crusher which reduces it to 2-in. size. It is then elevated on a Robbins belt conveyor to the fine ore bin, from which it is sent by a four-ton rope skip to mill-bins, from which it is fed by gravity to the stamps. Development work is being pushed eastward and vertically below the 1000-ft. level, keeping the ore reserves well in advance of mill requirements. The ore is principally white quartz, carrying galena, and iron pyrites. The method of mining consists of breast stoping and back-filling. The power-plant consists of two 500-ft. Sullivan power compressors, driven by two 150-hp. Nash gas-engines, using distillate as fuel, and two 300-ft. Sullivan steam compressors. The power for operating the stamp-mill is also supplied by two 150-hp. Nash gas-engines. The water-supply for camp purposes and the boilers comes from a 1000-ft. well, while water for the mill is pumped from the mine, which furnishes an adequate supply.

The total value of the mineral production of Alabama, exclusive of the value of the pig iron, but including the value of the iron ores, was \$30,641,983 in 1912 and \$28,005,785 in 1911, approximately two-thirds of which is represented by the output of the coal mines and one-fifth by the output of iron ore. The iron ores of Alabama, while inferior in quality to those of Lake Superior, have the advantage of being near deposits of good coking coal and of the limestone requisite for fluxing, so that Birmingham, the Pittsburgh of the South, can manufacture pig iron cheaper than any other district of the world.

Gold, silver, lead, and copper output of Charters Towers, Queensland, in October was worth \$115,000. The Deep Sinking Commission has finished its work and furnished a report. Briefly the report recommends a reduction in the diameter and depth of the proposed shaft, and an increase in the capital to be provided. It remains to be seen how this recommendation will be dealt with by the Queensland Government and Mr. Mills.

After a lapse of eight months, the British Australian Oil Co.'s shale mines at Murrumbidgee, New South Wales, Australia, and works at Newcastle, are resuming operations. A new company has been registered in London, with a capital of £300,000, and it is proposed to recommence at once the manufacture of crude and refined oils, sulphate of ammonia, candles, and all products of coal shale oil and petroleum.

During September the Mt. Bischoff Tin Mining Co., Waratah, Tasmania, produced 100 tons of tin oxide, from the treatment of 20,806 tons of crude ore by the concentration plant. All the open-cuts are producing average-grade ore.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—You have been good enough to ask me to contribute to a discussion on Mr. C. B. Horwood's articles on the 'Rand Banket' now appearing in the *Press*, and as this is a subject to which I have given much attention, and on which I have written not a little, I have much pleasure in acceding.

On main principles, Mr. Horwood and I appear to be in accord: thus he agrees with me that the gold has been introduced after the deposition and cementation of the pebble beds that now form the conglomerates.¹ In regard to some minor matters, however, there are points of difference between us, as I shall endeavor to show later.

Mr. Horwood gives prominence to the question of the origin of the so-called pyrites pebbles, and rightly, because their existence in the banket has been one of the chief arguments brought forward by the supporters of the alluvial theory. We are agreed that rolled pebbles of pyrites—that is, pebbles of pyrites formed by attrition with the quartz pebbles of the conglomerate—do not exist in the banket; further that certain flattened or ellipsoidal pyrite pebbles which are microcrystalline and entirely devoid of radiate structure, are pseudomorphs after quartz pebbles. But this variety of pyrites pebble is exceedingly scarce in the banket; the bulk of the nodules and pellets of pyrites shows a distinct radiate or concentric structure, and are ordinary concretions of pyrites. Such concretionary pyrites is quite common in the banket, and although it may be in part of metasomatic origin—that is to say, during its introduction it may have replaced a portion of the silica of the groundmass of the banket—I cannot agree with Mr. Horwood in regarding this particular variety of the nodular pyrites as pseudomorphs after quartz pebbles; nor do I understand his explanation of the radiate structure, which, in the cases I have seen and described, is a property of the pyrites itself, similar to that of other well known concretions of that mineral, and not a septarian structure.

Mr. Horwood has done good service in collecting, and in reproducing by photography so much valuable material, which will be of great assistance in making clear the nature of the process by which the pyrites has been introduced into the banket. But he cannot be given all the credit for the discovery of its metasomatic origin. This has been the work of several. Even the possible pseudomorphism of pyrites after quartz pebbles was simultaneously sug-

gested by several observers; although the idea only assumed concrete shape when Mr. C. R. Young brought the microscope to bear on it. Mr. Horwood bases a claim to priority for this discovery on a paper read before the Geological Society of London in March 1907, and states² that the "view was a new one, advanced for the first time, and it met with a considerable amount of opposition." Unfortunately the paper was not accepted for publication, consequently all that appears in the *Quarterly Journal* of the Society is its title and a footnote setting forth that it was "withdrawn by permission of the Council."³

As the subject is of some importance, perhaps I may be permitted to review briefly the whole discussion. The existence of pyrites 'pebbles' or pellets in the banket has been known for a great number of years, and their origin has been the subject of much discussion. The so-called 'buckshot pyrites' of the Rietfontein series was described by myself in the 'Gold Mines of the Rand,' a joint production of the late J. A. Chalmers and myself. Then came

²*Mining and Scientific Press.*

³A brief abstract of the papers read before the Geological Society is circulated to the Fellows immediately after the meeting. The one referring to Mr. Horwood's paper is No. 841, March 5, 1907, p. 54. As these 'Abstracts of the Proceedings of the Geological Society' are not everywhere available, it may be useful to reprint the abstract of Mr. Horwood's paper. It is as follows:

"THE OCCURRENCE OF PSEUDOMORPHOUS PEBBLES OF PYRITES AT THE CROWN REEF MINE (WITWATERSRAND), by C. B. Horwood.

"Reference is first made to the existence of calcite 'pebbles' in the Main Reef, which Julius Kuntz believes to be due to the replacement of quartz by calcite. Pellets of iron-bisulphide known as 'buckshot' occur at the Rietfontein 'A' mine in the Buckshot Reef; they exhibit radiate fibrous structure, and are probably of concretionary origin. At the Crown Reef mine a few 'pebbles' of pyrite—some measuring as much as an inch in length—occur in a narrow band of conglomerate at the contact of the reef with a basic dike. It is conjectured that the mineralizing solutions which deposited the pyrites (together with some, if not all, of the associated gold) ascended along the fractures due to the intrusion of the dike, and found an easy course along the small conglomerate bed, where they replaced some of the quartz pebbles with pyrites, being kept up by a band of shale underneath the conglomerate."

The only discussion which took place at the meeting consisted of the following remarks made by myself:

"Dr. F. H. Hatch said that the abstract of the paper read by the secretary did not contain any facts tending to show that any of the pyrites nodules in the Witwatersrand conglomerate were really pseudomorphs after quartz pebbles; nor was there any suggestion offered as to how such a replacement might be supposed to have taken place. The specimens on the table contained abundant examples of pyrite nodules with radiate structure, which were evidently of concretionary origin. The speaker had not, however, noticed on the table any specimens that showed clear evidence of pseudomorphous origin. Pyrites occurred in the Witwatersrand conglomerate in three forms, namely: (1) in crystals; (2) in concretionary nodules with radiate structure; and (3) in flat pebble-like bodies of amorphous structure. The last named had been described by Becker and others as 'rolled pebbles of pyrites' and it was no doubt to those that the author referred as 'pseudomorphous pebbles.' Anything approaching a proof of their pseudomorphism would have a bearing on the mode of origin of the gold in the conglomerate."

"Gold Mines of the Rand," Hatch and Chalmers 1895, p. 51.

¹See Hatch: 'The Geology of the Southern Transvaal,' *Quart. Jour. Geol. Soc.*, Vol. 54 (1897), p. 81; and Hatch and Corstorphine: 'The Petrography of the Witwatersrand Conglomerates, with Special Reference to the Origin of the Gold,' *Trans. Geol. Soc. So. Af.*, Vol. VII (1904), p. 145.

(in 1897) Becker's⁵ description of the pyrites pebbles as of detrital origin, which he used to support his argument that the gold was of alluvial origin. In 1904, in conjunction with my friend, Mr. Corstorphine,⁶ I again took up the cudgels against the alluvial theory, and in support of the infiltration theory. We recognized the importance of the origin of the pyrites pebbles, and devoted especial attention to the examination and distribution of a number of typical specimens from the Buffelsdorn mine and from the Rietfontein mines, noting the radiate, and, in some cases, the concentric structure. We also examined a great number of slides made from specimens obtained from different mines, in which, while we described the pyrites as of all shapes, we pointed out that the spherical predominated, although some of the particles were sharply angular and showed crystal facets. We expressed our opinion that the bulk of the so-called rolled pyrites was of concretionary growth; and added that if rolled pebbles of pyrites really occur, we had not seen any to which we could assign such an origin. The same views are stated in our joint work on the 'Geology of South Africa.'⁷ Later on we came across pyrites 'pebbles' that showed no concentric or radiate structure and possessed a curiously flattened or ellipsoidal shape, and we admitted that these certainly did recall the appearance of true pebbles. The possibility of this being pseudomorphs after quartz pebbles suggested itself,⁸ and was freely discussed among those interested in the subject at that time in Johannesburg; but it remained a mere supposition until it was proved by the careful microscope work of C. R. Young,⁹ which was embodied in a paper read before the Geological Society of South Africa on March 18, 1907. A few days previously, on March 5, 1907, Mr. Horwood's paper had been read before the Geological Society of London; but it contained no proofs and was, as already stated, withdrawn without publication.

The subject was again dealt with in the discussion on Mr. Gregory's paper on the 'Origin of the Gold in the Rand Banket,' read before the Institution of Mining and Metallurgy in October 1907. His paper contains a photograph of two of the flattened non-concretionary pebbles referred to. Mr. Gregory, being a strong supporter of the alluvial theory, appears to think that they have been worn by attrition to their present shape; but he does not deny the possibility of their pseudomorphous origin, although in that case he prefers that they should be pseudomorphs after ironstone instead of after quartz. That the idea of the pseudomorphous origin of the pyrites was in the air, prior to the reading of Mr. Horwood's paper, is further shown by the fact that Mr. Gregory also suggested it in a lecture at the Society of Arts

which was given on February 4, 1907.¹⁰

Finally the whole subject was reviewed by myself in 1911 in a contribution to 'Types of Ore Deposits,'¹¹ where I described the pyritization of the banket as a case of metasomatism belonging to a post-cementation period, since (as C. R. Young had already shown) not only are occasional pebbles, but also the cement of the banket, in part replaced by pyrites.

F. H. HATCH.

London, November 21.

Gold in Surinam

In Surinam, Dutch Guiana, gold-placer deposits have been worked since 1879, but there have been few improvements in the methods of operation from that time up to the present. The concentration of much of the gold in rich pockets has enabled the miner to work the placers by primitive methods and still make a good profit. The smaller and richer spots of the placers are profitably worked by many of the gold-diggers, for there is only a moderate overburden and the bedrock gravel is reported to carry about \$5 in gold per square yard of surface.

The more extensive gravel deposits carry much smaller quantities of gold, but they might be profitably worked by improved modern methods, provided they were first carefully examined and prospected. The low grade of the large gravel deposits, together with the lack of water (or an excessive oversupply) make the exploitation of these fields impossible for the man of small means. The small rich spots in many of the placers do not seem to be exhausted, but still afford attractive opportunities for the energetic and optimistic gold-digger.

A recent official report, published in London, gives interesting details of gold-mining in this colony. Encouraging results had been obtained in the Kaituma and Barima rivers, but the outstanding feature of the year was the richness of claims located near Pigeon island, on the left bank of the Cuyuni river, the return of gold surpassing anything hitherto worked in the country. From one creek, in which 70 to 80 'toms'* were in operation, a day's work yielded as high as 60 oz. per 'tom', and on rewashing sand, 30 to 35 oz. per day; worked for a third time, 12 to 15 oz. per day was won, and the fourth time the diggers were rewarded with a return of 4 to 5 oz. for a day's work. Following these rich discoveries on Pigeon island, gold, it was reported, had been found over an extensive area at the head of the Caburi creek on the Mazaruni river. There was also a rich find reported in the upper Mazaruni, and if the statements of the finder could be given credence, a substantial addition to the gold output would result from the discovery. The gold output of the colony for 1912-13 was 62,098 oz., as compared with 49,607 oz. in the preceding year.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Coal sold by the Chinese Engineering & Mining Co. during its last financial year totaled 1,728,296 tons.

Products of mines, largely coal, account for 55% of the total tonnage handled by railroads in the United States.

Good wagon-roads and trails are badly wanted in Alaska. A prospector near Valdez, during the past season, had to pay from 5 to 12c. per pound to haul three tons of supplies.

Costs of producing 'blister' copper at Mt. Lyell, Tasmania, during the past half-year were: mining, \$2.50; smelting, \$2.54; and bessemerizing, \$0.28; a total of \$5.32 per ton of ore treated.

Fuse is frequently injured by falling rock or other causes. Such injury increases the burning rate, and there have been cases where fuse damaged in this manner have burned almost instantaneously.

'Pork-knockers' are placer miners who work on ground that belongs to mining companies in British Guiana, South America. Although they are trespassers, they are steadily producing a fair quantity of gold.

Two 120-hp. Crossley suction gas-engines, driving a 20-stamp mill and 10-drill air compressor, respectively, at the Central Red, White, and Blue mine, Bendigo, worked the last half-year without any stoppages due to the engines themselves.

There is danger in using frozen or chilled explosives. Most dynamite freezes at a temperature of from 45 to 50°F. Priming or the placing of a detonator or electric detonator in dynamite should not be done in a thawing house or magazine.

Quicksilver ores, after being sorted to some extent, are generally treated direct in furnaces. Lately, however, there have been plants erected for crushing and concentration of these ores, especially when low grade. Although cinnabar has a specific gravity of 8.99, the millman must be careful not to crush the ore too fine, otherwise there will be a considerable loss from whatever type of concentrator is installed.

Fire in the North Lyell mine, Tasmania, necessitated its being flooded late in 1912. Early in June 1913 unwatering was completed, having taken 4½ months to bail 41,500,000 gal. of water. The precipitation plant recovered 146 tons of precipitate containing 63 tons of copper. In addition, 109 tons of precipitate, with 16 tons of copper, was cleaned up in the mine workings, representing the copper precipitated by steel and ironwork, etc., out of the water with which the mine was flooded. Although the loss by the disaster was \$201,000, there was re-

covered \$27,000 of copper precipitated during the flooding of the mine.

Unit is a word employed in smelting contracts and means 1% of the metal or other constituent of the ore to which the word is applied. Thus, a 'unit' of lead or of iron means 1% of these metals, or 20 lb. of lead or iron per ton of ore. The smelters usually make payments per 'unit' for the desirable constituents of an ore, and charge the shipper for each 'unit' of the substances which they do not want. For example, many smelters exact a 'zinc penalty' of 40 or 50c. per 'unit,' which means that an ore containing 10% zinc would be subject to an extra charge of \$4 or \$5 per ton.

Gold mining in Hungary is mostly done in Transylvania, in the eastern portion of that European country. At Boieza there are eight separate mines, according to Newton B. Knox. The ore, as a rule,

PLANT AT THE BOIEZA GOLD MINES, HUNGARY.

is free milling, containing from \$4 to \$12 per ton. There is only one mill, with 50 stamps, remaining in the district, and gold recovery is low. The accompanying halftone shows the character of the country and surface buildings at Boieza.

Important minerals of commercial value occurring in the Joplin district are galena, cerussite, sphalerite, calamine, and smithsonite. These are better known locally as 'lead' for galena; 'blende' or 'rosinjack,' 'rubyjack,' 'steeljack,' or 'blackjack' for sphalerite; and calamine and smithsonite are classed together under one term as 'silicate.' Closely associated with these minerals are pyrite, marcasite, chalcopyrite, calcite, dolomite, and, in a few mines, small crystals of quartz. These minerals also have their local terms, such as 'mundie' for the iron sulphides, 'tiff' for calcite, and 'spar' for dolomite. Besides these, in a few of the mines there are small deposits of the hydrocarbons, which are termed by the miners 'coal tar' or 'asphalt.' This substance occurs in small openings or crevices, and is usually viscous at the ordinary temperature of the mines. A yellow to light-brown clay also occurs, especially in the 'soft-ground' deposits, and, although it is not a definite mineral, it in many places contains considerable zinc silicate. Other minerals occur throughout the district, but are less common and important.

Special Correspondence

AUCKLAND, NEW ZEALAND

LABOR TROUBLES AGAIN.—THE YEAR'S RESULTS AT THE THAMES, COROMANDEL, KARANGAHAKE, AND WAIHI DISTRICTS.—GOLD MINING IN THE SOUTH ISLAND.—COAL, OIL, AND KAURI GUM.

It is unfortunate that labor troubles have again interfered with the output of minerals in New Zealand. It is estimated that the loss during the year to shareholders in mining companies through strikes was about \$240,000, and to the employees quite three times that amount. The regrettable point is, that such figures appear to have little weight with those who start disputes, as toward the close of the year the men were once more called out from the coal mines, and the trouble spread to other trades. The result was that the ports were closed for a few weeks, until the farmers got anxious regarding the shipment of their produce and resolved to ride into the towns and assist the authorities. In Auckland about 1500 farmers came to town bringing their own horses, and nearly 1000 citizens were also sworn in as special constables. This resulted in peace, and when the strikers found that they were not entirely masters of the city, work in the port was resumed. The total value of the gold and silver exported from New Zealand from 1857, the year in which the first discovery was made, until the end of 1912, was \$395,500,000, to which may be added about \$6,200,000 for 1913. To November, five mines in Ohinemuri county in the Hauraki peninsula produced \$3,370,000, as follows: Waihi, \$1,330,000; Waihi Grand Junction, \$720,000; Waihi-Paeroa Extraction Co., river dredging, \$160,000; Talisman Consolidated, \$940,000; and New Zealand Crown, \$120,000. These properties have already paid over \$27,000,000 as dividends. The year 1913 has been somewhat disappointing, as far as mining was concerned, in the Auckland district. It was naturally thought that when the strike terminated in Waihi, in October 1912, there would be a revival of interest in mining. Such, however, was not the case. It would appear as if investors had their eyes opened by that strike, and are less inclined to spend money in an industry in which labor troubles have to be added to the ordinary risks. That there have not been any important new finds on the Hauraki peninsula during 1913 is hardly to be wondered at, seeing that little prospecting has been done, owing to the fact that there has been plenty of work at good wages for ordinary laborers.

In the Thames goldfield, the most important work has been the continuation of the cross-cut at 1000 ft. for the purpose of testing the deep levels. Over \$96,000 has now been spent on this work. In November, operations had to be stopped, owing to a heavy inflow of gas and water, supposed to be the result of the proximity of the Moanatahuri fault. There is, however, an equal probability that this may prove to be the Waiotahi vein, but this will not be proved until more work has been done. The Kuranui-Caledonian company, which has its headquarters in London, has reconstructed in order to provide capital to develop that property, as soon as the drift gets near its shaft. The Waiotahi mine, which adjoins, has started sinking its shaft to 1000 ft. The May Queen is driving at that depth to cut the Vanguard vein, and the Saxon has opened No. 7 level to reach the Cardigan vein. The Watchman mine at Thames has been systematically developed for a few years, and 1000 tons of ore treated at the Waiotahi mill proved that it is a paying proposition. A stamp-mill has therefore been acquired, and this is being overhauled for regular work. The New Sylvia mine has been producing fair-grade ore for several months, yielding a profit on each return. A long low-level adit driven at great cost by the Waitangi Consolidated company, failed to find the veins at depth, so that operations were resumed at the upper levels, where recent assays showed the ore to be profitable. In the Kuranui mine, important developments took place toward the end of the year. The

directors abandoned the old policy of prospecting in the upper workings and started to continue what was known as the Magazine adit. In the first 100 ft. no less than three veins were cut, all being of a promising character, and five more veins are known to be farther on. In November a stringer showing gold was cut, so that there are hopes that the other veins will prove profitable.

Mining has been dull throughout the year at Coromandel, and at the present time only about three companies are carrying on active operations. One is the Hauraki Reefs, which adjoins the Old Hauraki, and from that mine several unfavorable reports have been rendered at intervals. The Mt. Welcome mine, at the Tokatea range, is driving a lower adit to enable work to be resumed in winzes,

from which some good ore was extracted until the men were driven out by water. The other mine being worked is Bremners Freehold, at Tiki, where it is hoped that gold may be found in the Tiernans vein. At Kuaotunu, the New Waitaia mine is yielding regular shipments, the ore ranging from \$43 to \$57 per ton.

In the Karangahake district, three companies are carrying on operations, the principal one being the Talisman Consolidated, whose mine is opening well on the lower levels, and is paying regular dividends. The total output from this mine to date, November 1913, reached \$9,700,000, out of which \$4,080,000 has been paid in dividends. The New Zealand Crown Mines Co. has not done anything of note during the year, the returns ranging from \$9700 in January to \$14,000 in May, and \$12,000 in September. As the ore treated for the latter month was 1323 tons, it will be seen that the ore is not high grade. The total output from the Crown Mines to November is \$4,300,000. Adjoining the Talisman mine, a local company is developing the Dominion property, where a large vein on the surface, which gave promising assays, is expected to be cut before long in the low adit now being driven.

Rather important developments have taken place at Waihi during the year, particularly toward the close of 1913. When operations were resumed at Waihi in October 1912, after the strike, it was thought that a barren zone existed at No. 10 level. This theory has since been entirely disproved. A vein was cut on that level, which has been named the 'Dreadnought,' and has shown by average assays that the ore is profitable. This discovery

at a depth of 1300 ft. gives hope that gold contents will be found deeper. The vein has since been found in the level above, but was smaller and poorer. This may be taken as an indication that it is an orebody which extends downward and improves in value as depth is attained. The Hora Hora electrical scheme, which has been carried out by the Waihi company at a cost of \$720,000, will shortly be ready for work, enabling the ore to be handled more economically. Up to November 1913 the Waihi mine has produced \$49,000,000, out of which \$2,100,000 has been paid in dividends. The latest report from the mine is to the effect that the Edward vein is opening splendidly at a depth of 1150 ft., both in respect to width and gold content, and the other veins were also looking well. It would therefore seem as if the dark days for the Waihi company were passed, and that there is still a good future for the greatest mine in New Zealand. Even more important were the developments in the Waihi Grand Junction mine, in the lower levels. When driving on the Empire vein, a fault was found, and on the other side, what was thought at first to be the same orebody was cut. Subsequent work showed this to be an entirely new vein, and the Empire was found again after a cross-cut had been driven 100 ft. The ore was opened for some distance

Cassius, Morning Star, and Excelsior companies were working, 11,543 oz. of gold was recovered in 35 days. Exclusive of the returns from the ordinary small claims, the output for about 32 weeks was valued at \$430,000. Subsequently, the Mont d'Or Sluicing Co. recovered 40,700 oz. from Ross Flat, and one man named Cassius got 22,000 oz. in two years, while at the top end of the field, known as 'Jones Flat', over five tons of gold was extracted. Later on, for a period of over ten years, all mining was suspended, as the properties were inundated with water. In 1882, the first Ross Gold Mining Co. was formed, but was only able to work in the gravel for 35 days, and during that period 614 oz. was won. Then the water in the Cassius workings was tapped, with the result that the Ross mine was flooded out, as the plant proved unequal to cope with it. In 1905 the Company went into liquidation, and it was not until 1907 that the Ross Goldfields, Ltd., was formed with a capital of \$384,000. An electrical plant and other machinery was installed, but once more shareholders were disappointed, and it was not until a Diesel engine had been installed, with additional pumping plant, that the mine was again unwatered. In the past, no less than \$960,000 has been spent by four companies in trying to unwater this ground. In sinking the Ross shaft, eight strata of gold-bearing gravel were passed through in 392 feet.

Gold-dredging seems to have passed its zenith in the South Island, yet the 80 dredges in commission returned \$1,290,000 in 1912, of which only \$72,000 was received by shareholders as dividends. Toward the close of 1913 the Big River company paid several good dividends. By the systematic testing of gravel areas with Keystone drills, placer mining has been rendered less speculative. The Consolidated group of mines at Reefton has produced steady returns during the year and paid several dividends.

The output of coal from the various mines in New Zealand shows steady increase. A new state coal mine has been opened at Seven Mile creek, near Grey-mouth, which is estimated to be capable of yielding 2000 tons per day. The Westport collieries still supply large quantities of excellent bituminous coal, and the Westport Stockton is stated to have 9,000,000 tons in its area. In the North Island, the Taupiri Coal Co. is the main source of supply of brown coal for household purposes, but a new company, called the Waipa Collieries, is developing property farther up in the Waikato district. A railway is being constructed seven miles, and there is a good seam of coal which can be worked by adits. Another company, named the Pukerimu, is also opening a mine, so that the supply of household coal should be ample for years to come for the Auckland province. North of Auckland, a good deal of bituminous coal is mined by the Hikurangi and Northern companies. During November all coal mines were shut down on account of the strike.

An area of 1850 square miles has been set apart by the New Zealand government for the purpose of boring for oil. About fourteen companies are now drilling for petroleum in the North Island, and a refining plant has been erected at Motura, Taranaki, at a cost of \$120,000, which will have a capacity of 10,000 gal. per day. During 1913 the New Zealand Oil Wells Co. was formed in London with a capital of \$1,920,000. This Company has already secured the government bonus of \$12,000 for the production of 250,000 gal. of oil. Several of the companies are interested in the refinery that has been erected, and six are now drilling with modern rotary machines. Indications of oil have also been found at Marlborough, Buller, and Ross, in the South Island, and at Ohinemuri in the Hauraki peninsula. North of Auckland, at a place called Pungare, there is a large deposit of oil shale, which is also receiving attention from a company.

The kauri-gum industry continues to be an important one for the Auckland province. At the extreme north of

KARANGAHAKE, NEW ZEALAND.

The Crown and Talisman properties are in the cañon below the mountain, which is 1700 ft. high. Ohinemuri river in foreground drains the Waihi, Waitekauri, and Karangahake districts.

and proved to be 10 ft. wide, averaging \$20.60 per ton. The Royal vein at this level was opened in November to 34 ft. of profitable ore, so that the future of this mine seems bright. The total return to date from the Waihi Grand Junction is \$3,700,000, out of which \$280,000 has been distributed in dividends. The Komata Reefs mine, which has produced \$2,110,000, reduced the number of employees toward the close of the year, as the total return for the 10 months had only been \$38,000. The Silverstream mine, at Maratoto, is producing telluride ore, and shipments varying from \$177 to \$240 per ton have been sent to a smelter for treatment. There is also a large vein on this property, known as Cumola, which is 40 ft. wide. This is free-milling ore and has been opened for 450 ft. and is profitable for the whole distance. A raise was driven 50 ft., and a winze sunk, in both of which the vein assayed \$14 per ton. At Waiorongomai, near Te Aroha, the Waitawheta Gold Prospecting Co. had the misfortune to have its stamp-mill destroyed by fire early in the year, just as crushing had been started. A new plant is being erected and fitted with vanners and a complete cyanide plant, so that treatment should be resumed early in 1914. This Company holds a combined area of 343 acres, as well as machine sites and ditches. It is considered that enough ore has been opened during the last few years to keep the mill in full operation.

In the South Island the story of the Ross Goldfields company is one of persistence on the part of shareholders in the face of many difficulties. This mine is situated at Westland, and in the early days of that field, when the

the North Island a company is to systematically work an area recently acquired. The kauri-gum market has been good throughout the year, the total exports from Auckland, the only port in New Zealand near where gum is found, was \$2,160,000 up to November 1913, an increase in value on the similar period of 1912 of about \$816,000. The value of the kauri gum industry to Auckland may be gathered from the fact that the total export to date amounts to \$180,160,000.

MELBOURNE, AUSTRALIA

BIG DIVIDEND PAYERS.—OIL IN SOUTH AUSTRALIA.—VICTORIAN COMPANIES LEGISLATION.—OIL FROM COAL.—A RICH MINE REVIVED.—'PICKING THE EYES OUT.'

In contradicting a misstatement made by a Tasmanian publication, to the effect that the Mt. Bischoff tin mine has paid more to its shareholders in dividends than any other mine in the world, the *Australian Mining Standard* recently gave some interesting figures as to the dividend payments made by Australian mines. Among the companies that are still carrying on operations, the following have made the largest disbursements:

Company.	Metals produced.	Dividends.
Broken Hill Proprietary	Silver and lead	\$47,762,800
Mount Morgan	Copper and gold	39,426,460
Great Boulder	Gold	21,939,823
Ivanhoe	Gold	15,035,000
Mount Lyell	Copper	13,417,884
Mount Bischoff	Tin	11,717,600

Next to these, not mentioned by the *Australian Mining Standard*, because its editor only wished to name those having paid more than Mt. Bischoff, is the Oroya Links company, of Western Australia, which, with the old Brown Hill and Oroya Brown Hill companies, all the property now being controlled by the first named, has paid out \$10,409,269.

Considerable interest has been aroused in South Australia by a difference of opinion that has unhappily found further ventilation in the columns of the press, between the government geologist, L. K. Ward, and Mr. Basedow, who was at one time assistant government geologist and has since been assistant government geologist in the Northern Territory. Mr. Ward, in the early part of the year, issued a bulletin in which he doubted the alleged discoveries of oil-bearing material on the northern coast line of the state. This naturally checked the flow of capital for the proving of those supposedly petroliferous areas; but the hopes of those who were concerned were revived by support of their theories from Mr. Basedow, who contradicted some of Mr. Ward's conclusions and said it would be a scientific mystery if so extensive a system of fossiliferous Tertiaries as obtained throughout the areas in question should not contain subterranean reservoirs of petroleum. Unfortunately a good deal of personal animus has been imparted into the discussion, and it seems to the impartial outsider as if personal animosities have had no small weight in the establishment of the differences of opinion that have been ventilated. It is now announced that an independent authority is to be appointed to inquire into and report upon the probabilities of South Australia having unknown oil reserves.

A bill has at length been introduced into the Victorian Legislative Council for the amending of the present state law relative to mining companies (no liability). The bill is mainly based upon suppositions and recommendations made over three years ago by a conference of the committee of the Stock Exchange of Melbourne, the Chamber of Mines of Victoria, and the mining attorneys. Its object is the better protection of shareholders and the public generally, and it provides penalties for the issuing of a false prospectus. It contains a clause providing that, before a company is registered and incorporated as a 'no liability' company, two-thirds of the proposed capital shall be subscribed and 5% of the capital subscribed must be paid in cash. It will be the duty of the manager to pay money and checks into the bank within seven days. Verified copies of the half-yearly balance-sheets and statements will have to be lodged with the registrar-general. Books of

accounts, balance-sheets, and half-yearly statements are to be open to the inspection of shareholders in and creditors of companies. The manager will have to give all reasonable information to shareholders as to the working of the company. Another innovation is a clause providing that no director or manager of a company shall be personally interested in a contract for profit made on behalf of the company. This is one of the most important of the clauses, for the extent to which directors have pocketed secret commissions and sold machinery of their own to companies, the interests of whose shareholders they are paid to protect, has become a scandal. It is to be hoped that the measure will become law.

Newcastle, New South Wales, is not greatly alarmed at the threat that oil will invade the domain that has hitherto belonged to coal. In fact, it is even hoping to derive some benefit from the output of oil for motive purposes. Some weeks ago, a shipment of ten tons of three different local coals was sent to England to be tested under the Del Monte process for the production of motor oils. One of the coals, from the Rothbury colliery, about 35 miles from Newcastle, was said to be rich in oil, and good results are expected from the trial. If the tests prove satisfactory, steps will be taken to erect a plant to treat the coal locally for the production of oil and by-products. The Rothbury colliery contains a large seam of coal, and estimates of the quantity under the area which is being worked vary from 50,000,000 to 100,000,000 tons. The seam gets thicker with depth. In any case, there is an enormous quantity of coal of the same nature as that sent to England to be tested, and if it is oil bearing, then there is enough of the mineral at Rothbury and under the adjoining country to supply Australia with oil for many years to come.

J. B. Jaquet, chief inspector of mines of New South Wales, has been reporting upon a new tinfield 60 miles west of Wyabong, and about the same distance northwest of the Ardlethan field. Though little work has been done, too small indeed for the forming of any very definite opinion, Mr. Jaquet does not hesitate to pronounce a belief in the future of the field, on the ground that it is traversed by genuine fissure lodes. The tin occurs in quartz along the junction of granite and slate, and in one shaft, which is down 50 ft., the lode is 5 ft. wide, with well defined walls. That being so, the prospects of permanence are certainly better than they ever were at Ardlethan. The new field is called the Conapaira.

It is not often that an old mine, when unwatered, proves up to expectations, but that seems to be the case with the Golden Springs mines, near Blayney, New South Wales. A good deal of ore was apparently left standing at the 250-ft. level, and a mining engineer of repute, who has reported upon the property, states that considerable work has been done off the lode, so that there is a probability of further work revealing an extension of ore that may prove very profitable, to say nothing of developments at depth. All the samples of ore taken have given good assays, varying from \$6 to \$17 gold per ton. The amount of ore immediately available cannot yet be determined, but there can be no doubt that the prospects of the Company are unusually good.

The inspector of mines of the Northern Territory has been examining mines east and southeast of Pine Creek, and is of the opinion that the usual custom of 'picking the eyes out' is being pursued, and that soon nothing will be left but low-grade ore and collapsed workings. It is due to the administration of the territory not insisting on timbering the underground workings, so that the danger of collapse may be avoided. As regards the other evil, it is difficult to see how it can be legislated against.

DULUTH, MINNESOTA

A NEW DRILL.—FIRST-AID WORK.—THE MINNEWAS MINE.

Apparatus recently introduced on the Mesaba Range, that promises to be of great value to underground mining methods, is the jack-augur drill. This drill is of the jack-hammer type, but has both a rotary and percussive action, using an augur bit. It will operate in ground that is too hard for hand augurs, what is called 'poke-bar ground.'

A bit about six feet long is used, and a two-pronged augur. The operator holds the drill against the face, the augur screwing the cuttings out. The rate of advance in this ground averages about a foot per minute, and one man operating the drill and going to different faces in the mine will drill about 50 ft. of holes in a four-hour shift. Where hard spots are encountered, the ordinary cross-bit is used. Trouble is frequently met by small pieces which break in the hole, and, turning with the bit, prevent its further advance. If the spoon will not go in, a flat-ended steel is inserted in the hole and the hard piece is broken with a blow or two from a sledge. In favorable ground it is possible to break enough ground for a set of timber, so that if the holes are properly placed room will be squared out with one round for a set of timber. This means from 10 to 12 ft. of advance per shift if the timber can be placed to render the place safe. The introduction of the drill will probably result in the organization at the mines turning from miners, as they are now, into drillers, shovelers, and trammers, with special timber gangs. At present the miners drill, shovel, and tram their ore, and put up their timber with the assistance of timber-

STEAM-SHOVEL AT ONE OF THE OLIVER MINES.

men. The gangs are mostly made up of two men per shift, and the rate of advance in hand-auger ground has been at the rate of from 3 to 5 ft. per day. With the contract system, as established on the range, it is not expected that this will make any difference with the labor, especially in view of the present decrease in production.

Bureau of Mines Rescue Car No. 8 has just completed its first round of the mines in its territory and gone back to headquarters at Ironwood, Michigan. The territory included in its district embraces the states of Minnesota, Wisconsin, and Michigan. Its trip on the Mesaba range was to Aurora, Biwabik, Gilbert, and Eveleth. This is the first government car to be situated in a metal-mining district, and is probably the forerunner of others to be placed as soon as funds for their equipment and maintenance are provided. The work done by the cars is to give instruction in first aid to the injured, and train men in the use and care of mine-rescue breathing apparatus. This instruction is given without cost to the companies or the employees. The car spends a week at each large property or group of mines, and instructs the men in the vicinity who wish to avail themselves of the opportunity. For the men who complete the course a government certificate of competency is issued. During this trip to the Mesaba range about 50 men were trained in the use of the oxygen-breathing apparatus, and about 150 in first aid. Since the car was brought to the Lake Superior district in December 1912, five or six hundred men have been trained in the use of the breathing apparatus, and about 1500 in the first aid to the injured work. In addition to this, the mining companies have been training their employees in the work, so that at the present time in the entire district it would not be wrong to assert that there are at least 1500 men trained in the use of the breathing apparatus and 3000 or 4000 competent first-aid men. The work of the car has met with approval, and a great interest has been taken in the work. The results of the work have been apparent on several occasions. The company physicians say that since the 'first aiders' began their work, the cases of in-

fection have notably diminished. The use of the oxygen-breathing apparatus in metal mines has already prevented a great loss of property. In addition to the work of training, the district engineer has also visited probably 100 mines and made observations, chiefly with regard to equipment, methods, and conditions as to safety. The results of this work will be published in pamphlet form for free distribution. Nearly all the companies operating in the Lake Superior region now have safety organizations of some sort. Some have regular inspectors who look after the work and see that the rules are enforced. Some very comprehensive sets of rules have been published covering all classes of surface and underground work, and a great deal of money has been spent in protective devices. While in some cases the matter has rather been carried to extremes, the general result is beneficial, and with the campaign of education now being carried on it is thought that the percentage of accidents will be materially decreased.

The Oliver Iron Mining Co. is preparing to open the Minnewas mine, between Eveleth and Virginia. The Duluth, Missabe & Northern Railroad Co. has a steam-shovel at work grading for tracks, and foundations have been built for an engine and boiler house. This is a large property and will probably be operated as an underground proposition. The mine was worked a number of years ago, but only in a small way.

DEADWOOD, SOUTH DAKOTA

HOMESTAKE DIVIDENDS AND OPERATIONS.—DRILLING FOR OIL AT ARDMORE.

It is stated that the dividend rate of the Homestake Mining Co. next year will be 75c. per share per month, an increase of 10c. over the present year. The stock has recently sold in New York for \$120 per share, the highest on record. Economies in operation, due partly to the successful operation of the Spearfish hydro-electric plant, and also to the new caving system of mining the surface ores, have made large profits available for dividends. Preliminary work on the new boiler plant, which will operate the steam-driven electric plant and the new hoisting engines at the Old Abe shaft, is well under way. Buildings are being removed and grading will shortly commence. With the new equipment at the Old Abe shaft, skips will be used for ore hoisting in place of the cages now used. It is apparent that this will effect a decided economy in delivering the ore to the rock-crushers.

At Ardmore, in Fall River county, near the southern boundary of the state, the Ardmore Oil Co. is sinking a well in the hope of finding an extension of the Wyoming fields, which lie in the same formation, directly westward. The rig is one of the best in the district, has a 72-ft. steel derrick, and as the hole was started with a 12-in. casing, it is stated that it will be possible to go 4000 ft., if necessary. A well sunk some years ago by a railroad company at this point, in a search for artesian water, is 1500 ft. deep and in the Benton shales for the entire distance, except that there was 30 ft. of sandstone, which produced a poor quality of water. This well was abandoned when the tools were lost. The Ardmore company has five-year leases on 30,000 acres of land. The leases carry a clause allowing privilege of renewal for 25 years. It is expected that a depth of 1500 ft. will be attained shortly after the first of the year, at which time some interesting results may be expected.

CALGARY, ALBERTA

PROSPECTS OF OIL IN THE PROVINCE

Further details of the oil rush in the neighborhood of Athabasca landing, Alberta, show that the excitement was caused by the operations of O. T. Ross, an oilman from California, who had been making investigations for some months. These convinced him that a deposit probably existed on the Athabasca river, about 50 miles northwest of the landing. He interested W. T. Shillington, a financier who has been connected with Cobalt mining enterprises, in the project, and staked several claims. A stand-

ard oil-drilling outfit will be taken in this winter, and work will begin in the spring. Mr. Ross states that they will be prepared to go down 4000 ft., though he does not anticipate having to drill anything like this distance. As soon as the public heard of the enterprise, a rush to take up claims in the vicinity set in, until over 300,000 acres were taken up on the chance that the operations of Mr. Ross and his associates may be successful. In the meantime, the efforts of promoters to organize companies on the basis of the find near Calgary appear to have fallen flat. The public is by no means speculatively inclined at present.

NEW YORK

BUSINESS STAGNATION.—LABOR AT LAKE SUPERIOR COPPER MINES.—GRANBY CONSOLIDATED DOME MINE.—DREDGING IN COLORADO.—SOCIETY MEETINGS.

Conditions in various industries in the country are bad, and reports from the Middle West are discouraging. The National Lead Co. has laid off three-fourths of its men, the American Car & Foundry Co. has followed a previous reduction of 250 by laying off 300 more men, and the National Enameling & Stamping Co. has reduced its working force one-half. Both the American Steel Foundry, at Granite City, Illinois, and the Corn Products Refining Co. have entirely shut down, throwing 2700 men out of employment. The Illinois coal mines have only been working three or four days a week for some time, reflecting the depressed condition of the iron and steel business. Altogether, everything points to a hard winter, and the mining men can console themselves with the thought that they are at least much better off than anyone else. Newspaper reports state that the mining companies are planning to import large numbers of miners into the Lake Superior district after the first of the year unless the strike is settled by that time. The strikers demand recognition of the Western Federation of Miners, the eight-hour day, and the abolition of the one-man drill. The operators are ready to agree to the eight-hour day, but the absurdity of the demand to give up the use of the one-man drill is shown by the fact that its use has cut the cost of stoping from nearly 50c. down to 15c. per ton. As a result, mines which would otherwise have had to shut down long ago are able to continue work at a small profit. Thus instead of the one-man drill robbing men of jobs, it is actually the means of giving employment to a large number of men, for, except for the Calumet & Hecla, practically all the Lake Superior mines work very low-grade material at an extremely small margin of profit. Everyone who has impartially considered the matter agrees that the Western Federation is unworthy of recognition, but it seems unreasonable to maintain that no union will be recognized. The miners are obviously entitled to organize themselves if they want to, and if a union were formed and officered by men of character and intelligence it is probable that both the operators and the miners would benefit by it.

As a contrast to the state of general business, it is pleasant to speak of a company which is more prosperous now than it has been. The Granby Consolidated reports that its operating profits for the four months ended November 1 amounted to \$254,000. The work of building the new smelter is well advanced, and the date of beginning work is set at January 15. As an adjunct to the smelting work, a copper property, the ore of which carries excess lime, has been secured, and also limestone quarries for flux. The properties of the Snowshoe Gold & Copper Mines, Ltd., have also been taken over, the total investment in all these properties amounting to \$275,000. The development in the Hidden Creek mines has proved a reserve of 8,000,000 tons of 2.2% copper ore.

Much interest has been excited by the report of the Dome Mines Co., Ltd., which shows that in November the 13,820 tons of ore milled yielded \$121,100, or at the rate of \$8.76 per ton, while the October yield was at the rate of \$9.60 per ton, but from a less tonnage. As these yields compare with \$6.50 per ton in September and \$6.31 in August, speculation is keen as to whether the orebody of the 'big Dome' is showing a marked improvement which is likely to be persistent or whether the stopes are temporarily in ore of higher

grade. It is no secret that the Dome has been decidedly disappointing, on the whole, and it is to be hoped that the better returns will persist. The officials of the Company maintain a sphinx-like silence, but as that has always been characteristic of the International Nickel Co., it is not particularly significant. International Nickel is at last beginning to feel the depression in the steel industry and reports a recession in business during the past two months. The Company is in a good position to stand this, though, for earnings this year are above what they were for the same period last year, and expenditures for new construction have been less.

A development of great interest which has attracted little attention is the news that the Tonopah Placers Co., a subsidiary of the Tonopah Mining Co., has taken over five new placer claims, aggregating about 3000 acres, in the Breckenridge district of Colorado. The Tonopah company has been looking for good properties for some time, and its venture into the placer-mining field is interesting both for that reason and because Colorado placers have not been much in the public eye of late. There are four dredges in the Breckenridge district, but only three were working last year, the Colorado Gold Dredging Co., a subsidiary of the General Development Co., having partly dismantled one of its 9½-ft. boats. This Company handled 1,270,400 cu. yd. in 1912, with an average recovery of 16.4c., at an average working cost of 5.6c. per cubic yard. The other two dredges are the *Reliance*, a 9-ft. boat working in French Gulch, and the Bucyrus boat of the French Gulch Dredging Co. As the total gold yield of the county in 1912 was only \$426,000, these two boats cannot have contributed much to the total.

Cordiality of the relations existing between the Mining and Metallurgical Society and the American Institute of Mining Engineers, was well shown last week when the New York section of the Society and the recently organized coal and coke committee of the Institute met in adjoining rooms in the Engineers Club. The president of the Society, H. M. Chance, was chairman of the committee. After the committee had concluded its business it adjourned, in response to an invitation, to the next room and took part in the general discussion of the one-man drill, which was the topic of the evening.

JOPLIN, MISSOURI

PRODUCTION AND PRICES FOR 1913 COMPARED WITH 1912.—
OVERCOMING HEAVY WATER IN SHEET-ORE DISTRICTS.—
WORKING ABANDONED MINES.

The year 1913 will give an aggregate valuation for zinc and lead ores from the Missouri-Kansas-Oklahoma district close to \$15,000,000, which makes it one of the big years of the district's history, despite the fact that unusually low prices have prevailed. Compared with past years, this figure, \$15,000,000, is a good one. Only 1912 exceeded this output, the total valuation being slightly over \$18,000,000. The year closes with zinc-sulphide concentrate selling for \$35 to \$40 per ton, basis of 60% metallic zinc; while premium grades, high in metallic zinc, sell as high as \$42. Spelter at East St. Louis is weak at \$4.90 to \$5 per 100 lb. For the corresponding period of 1912 zinc sulphides brought from \$53 to \$56, basis of 60% metallic zinc, with the choicer grades selling as high as \$59. Spelter was then quoted firm at \$7.15. Calamine ore is in weak demand at \$18 to \$20 per ton, basis of 40% metallic zinc, with choicer lots selling up to \$24. For the corresponding period of 1912, calamine brought \$27 to \$30, with the choicer lots bringing as high as \$36.50. Lead ore is unsteady at \$48 per ton, basis of 80% metallic lead; while pig lead, East St. Louis quotations, is unusually weak at \$3.85 to \$3.90. For the corresponding period of 1912 lead ore brought \$53, and metal was quoted at \$4.15. Several important development undertakings were launched this year. New mineralized areas have been opened in several parts of the district. The importance of soft-ground mining has been a great factor in maintaining a fair average for the district, as sheet-ground operations have lagged to a great extent, due chiefly to the low prices which have prevented this work at a profit.

The North Webb City sheet-ground field continues to be a good producer of zinc ores, although production has been curtailed to a great extent by low prices. In the average sheet-ground mine it is possible to extract the richer ore-bodies, leaving the thinner ground to be mined out when prices are at a figure permitting profitable development. Heavy water has forced the North Webb City operators to coöperate in the cost of maintaining a central pumping plant, which is being operated at the Providence mine. The shutting down of the Yellow Dog mine, early in 1913, caused water to rise in the abandoned drifts until the overflow is finding its way into the adjoining properties on the south, where operations are conducted at a depth of 200 feet.

After large companies have given up a lease, it is often profitable for individuals to go into the old ground and continue production. Often the restrictions of mine liability are such that a large company cannot afford to continue work in treacherous ground, fearing heavy losses from injuries to workmen; yet these same workmen, if employed on their own responsibility, will not hesitate to go into the same ground and mine out the rich deposits that have been left. They will face the risk of personal injury where big profits are assured. An instance of an old mine being a good money-maker for individuals is that of the Kramer company at Cave Springs, Missouri, where a large mill was operated for some time. Not that the ground was dangerous did the Company suspend work, but because ore prices became so low that a great bulk of the thin 'dirt' could not be handled at a profit. The individual operators, however, to whom the property has now been leased, are enabled to go into the old drifts and work only the richest pockets of ore that remain, and thus they are making the old mine a paying one again. The reduced cost of management is one of the chief reasons why individual workmen can operate profitably where a large company, with a big expense, could not succeed.

The mill of the Pocatella Mining Co., on the Snapp land at Thoms Station, has begun operations and is producing steadily. The ore contains a high percentage of metallic zinc and regular turn-ins are being made.

RHODESIA

RESULTS OF MINING OPERATIONS IN 1913

The year now drawing to a close has been quite similar to 1912, in so far as mining operations in Rhodesia are concerned. There has been a further material, though not great, advance in mineral production; and also a continuation of the efforts initiated about three years ago, which are to bring six important gold mines to the productive stage in the near future. The situation in regard to native labor has shown no marked changes, but on the whole the position in this regard may be said to have improved somewhat. During the first nine months of the current year there has been £2,162,477 of gold produced. Other minerals were £180,172, making a total of £2,342,649, against £2,964,597 for the whole of 1912. The 1913 output may be figured at about £3,125,000, a record production for the country.

Trial runs of the new plant at Antelope mine, capacity 3000 tons per month, have been made, and both this property and the Beil mine will enter the producing list by the end of the year. There has not been such a serious scarcity of water as there was in 1912, and this has undoubtedly contributed toward the larger output.

There have been no sensational discoveries made during the past twelve months. Prospecting has continued with great vigor, but while numerous lodes, hitherto not located, have been opened, nothing that promises to develop into a large and profitable orebody has been found. In this respect the past year was an exceptional one, as in most of the past years there have been one or more reports of a sensational discovery, and which have in one or two instances been confirmed by subsequent development, but which in the majority of cases have proved to be quite uncalled for. In addition to the knowledge of the various mineral belts of Matabeleland and Mashonaland that is continually being added to by individual prospectors and small syndicates, the Geological Survey of Rhodesia has extended

its sphere of investigation and has collected considerable valuable data.

H. B. Maufe, the director of the Survey, has closely examined the association of gold deposits with igneous rocks, and the results of his work are embodied in an important bulletin issued about the middle of the year.

In regard to the older and more or less established producing mines of the country, it must be admitted that 1913 has given many disappointments, the bitterness of which is reflected in stock exchange prices. The Eldorado Banket company, operating at Lomagundi, has had to reduce its yield and profit, as result of less favorable developments in the lower levels. The Giant company proposes to acquire the Cam block of claims hitherto belonging to the Cam & Motor company, and distinct from the Motor lode. This enterprise on the part of the Giant company's directors has been construed into an admission that all efforts to re-locate the faulted orebody in the Company's mine at Gadzema, have failed.

As to the leading producer of the country, the Globe & Phoenix at Que Que, while revenue, profits, and ore reserves have been fairly well maintained, there has prevailed a spirit of uneasiness among shareholders. For the reputation of the Company, it is good to learn that the directors have now agreed to accept a smaller percentage of the profits. It must be admitted that in the past their fees were very high. The Company has recently ordered extensive equipment for the new shaft and evidently further development will be undertaken. As to other gold mines, the Lonely Reef has had another satisfactory year. At the end of June the ore reserves aggregated 134,000 tons averaging over one ounce per ton. The Rezende mine, which now includes the Penhalonga, also had a good year, recent profits having been at the rate of £2600 per month. As to the new and large gold mines which are expected to enter the producing stage within the next month or two, there appear to have been some delays in the delivery of machinery; but at both the Shamva and Cam & Motor construction work has reached an advanced stage. The essential features of these plants have already been described. Each proposition is in a strong position as regards development. At the end of June last, the Shamva's ore reserves amounted to 2,300,000 long tons worth \$5 per ton; while in the Cam & Motor there are nearly 1,000,000 tons of over \$10 ore blocked out. The Falcon, a large gold-copper property in the Gwelo district, is also being equipped and should help to swell the mineral output of Matabeleland next year. This mine has recently come into one unfortunate notoriety on account of discrepancies in assays between sampling made by the owners of the mine, and Messrs. Ackermann and Pickering of the British South Africa Co.'s mining department. Ore reserves at the end of June last year were stated officially to be 817,000 tons, valued at \$11.76 per ton. In regard to the smaller gold mines of the country, those operated by syndicates, working owners, and limited liability concerns, with small capital, reference must be made to the continued good returns by the Pickstone gold mines in the Hartley district, and the high yields of the Criterion, Bulawayo.

The production of minerals other than gold has been principally made up of coal and chrome iron ore. The Wankie company's mines, in northern Matabeleland, have again been the only producing collieries in the country, and in addition to supplying the larger number of important mines in southern Rhodesia with coal, these collieries have also during the past year sent considerable quantities of coal and coke to the Tanganyika Concession's copper mines at Katanga, Belgian Congo. The Selukwe mines continue to export chrome ore. Production is regulated by shipping facilities at the port of Beira. In August chrome ore worth £26,143 was exported. During the first eight months of the year, diamonds worth £1759 have been found on the Somabula 'diggings.' There have also been satisfactory outputs of lead, silver, and asbestos, as in former years.

As to labor, it is worthy of remark that the Rhodesian Native Labor Bureau has first decided to remove from Bulawayo to Salisbury, and thus reduce expenses.

General Mining News

ALASKA

CORDOVA

The *Cordova Daily Alaskan* gives the following distances to the new placer districts. McCarthy to Shushana is the winter route. From Cordova to McCarthy, on the Copper River & Northwestern railway, the distance is 191 miles. The distance from Chitina to Chisana or Shushana is 225 miles.

Miles.		Miles.	
Chitina	0	McCarthy	0

JUNEAU

A bonus dividend, No. 104, of \$1 per share will be paid by the Alaska Treadwell Gold Mining Co., on December 29.

ARIZONA

Mining men of Arizona are pleased with a recent ruling of the General Land Office which requires that when an application for patent on a mining claim has been made, the proof submitted therewith shall be considered on its merits, and a certificate issued if it is found regular, regardless of any protests that may have been filed. Heretofore when an application has been presented, regular assessment work has been required till all protests were passed upon and patent issued. This assessment work, in addition to the work necessary to secure a patent, has in many cases worked a hardship. After this an applicant shall receive a certificate upon making his application, though the patent is withheld till protests are passed upon. No additional assessment work is required.

GRAHAM COUNTY

(Special Correspondence.)—The Stanley and Aravaipa mining districts cover an area of over 6 by 30 miles, and as the surface showing on the various copper claims is promising, the claim-holders continue to work in the hope that there will be better communication for the districts. Freight by wagon, 18 miles from San Carlos, costs 1 cent per pound. Several miners are extracting ore which averages 12% copper and 5 oz. silver, and hope to make this pay by shipping to El Paso. A good road can be easily constructed a distance of 25 miles, making direct connection with Globe to Bisbee.

Stanley, December 13.

MOHAVE COUNTY

The Copperville mill is in full operation. The distance between Yucca and the mines is 25 miles, covered in four hours by auto-trucks. Crushing in the 150-ton plant is done by a Symons disc machine and Hardinge ball-mill, while concentration is by 14 Overstrom tables. Power is generated by a 150-hp. generator driven by a Metz and Weiss oil-engine.

YUMA COUNTY

A carload of ore from the Bouse & McMahon mine, six miles southwest of Bouse, returned gold worth \$11,500 at the Selby smelter, near San Francisco. There is consid-

erable activity about this place, which has been named Goldzone.

CALIFORNIA

AMADOR COUNTY

A circular has been issued by the Keystone Mines Co., of Amador City, containing the position of affairs as given by the manager, C. R. Downs. An ore-shoot was opened on the 900-ft. level north drift, 700 ft. from the main cross-cut. A raise is up 40 ft., and the vein is well defined with profitable ore. It was decided to reopen the 1200-ft. level on this vein, and ventilating pipes were placed in position. The north drift was badly caved, and after 180 ft. of repairing, it was too difficult for further work, so a new drift was driven in the foot-wall of the old workings. On December 17 this was in 265 ft. The 2600-ft. level was sampled and assayed, and it was decided to drive an inclined raise on the vein, as it was figured that it had faulted. At 40 ft., this theory was proved to be correct, and there is 10 to 12 ft. of good ore, with promising conditions. A total of 871 ft. was driven and cross-cut, in addition to the raise, since the last report.

ZEILA MINE AND MILL, NEAR JACKSON.

The secretary, C. L. Culbert, states that receipts from June 10 to December 10, 1913, were \$36,372, and cash on hand at the latter date was \$3829.

With the exception of installing motors, the tailing-disposal plant at the Kennedy mine is complete. It is reported that Oakland people have secured an old mine in the county, and intend developing and equipping it at once.

BUTTE COUNTY

The South Banner Mining Co., owning quartz and gravel mines six miles from Oroville, in the Morris Ravine district, has secured further capital from London to develop its property.

ELDORADO COUNTY

It is reported that 1200 acres of land, between a point several miles below Plymouth and the Cosumnes river, and extending toward Latrobe, have been bonded by the Gugenheim interests, who will build a large dredge in the near future.

INYO COUNTY

A California company is about to drill for potash at Ryan, in the centre of Death valley. E. V. Gamble, head driller for the Railroad Valley Company of Nevada, is in charge of operations.

A fine-grinding and cyanide plant is to be erected at the Bishop Creek mine, equipment being supplied by the Colorado Iron Works. The remodeled mill will be as follows: 10 stamps, 45-in. Akins classifier, 5 by 16-ft. tube-mill in closed circuit, thickeners, agitators, and a 12-ft. Portland filter. E. Walter is superintendent.

MODOC COUNTY

There will only be about 40 men in the High Grade district during the winter. In the Modoc Mines Co.'s 50-ft. level a vein has been opened for 150 ft., and at 100 ft. depth the drift is in 75 ft. in fair ore. The main shaft is 200 ft. deep. Twelve men are employed. The Consolidated Mines Co. has four men working. The Dandy, Bergen, White Star and Mineral Springs, Evening Star and

Alturas, Tamarack, and others, will be developed by their respective owners during the season.

NEVADA COUNTY

A mass of gold and quartz, valued at \$700, has been extracted from the Red Ledge mine near Washington. The specimen was exhibited at Grass Valley. At the Oustomah, sinking is still in progress. At the Golden Center, Grass Valley, 17 men are employed. The shaft is down to 500 ft., and rapid progress is made in using Leyner drills. A new stamp-mill is being built by Robert Hathaway, of Nevada City, and early in January it should be ready.

PLUMAS COUNTY

The owners of the Plumas-Eureka claims at Johnsville are preparing to increase the yield next spring. Six miles from Portola, rich copper ore has been discovered. Work is to be resumed in the Poker Flat shaft, which is down 800 ft. in lava. The Claybank gravel claims are being developed again. The Black Diamond quartz mine, on the ridge between Hopkins and Slate creeks, has been bonded to M. Duvall.

SHASTA COUNTY

Various reports have been current regarding the new mill for the Mountain Copper Co., which is to have a capacity of 250 tons per day, and will include concentration and probably the flotation process.

TRINITY COUNTY

The Weaverville *Weekly Trinity Journal* of December 6 has a special supplement illustrating the mineral and other

GLOBE MILL AT DEDRICK, TRINITY COUNTY.

resources of this county. In 1912 the gold yield was valued at \$723,503. There were 85 producing mines and 59 placer properties, the former yielding 57,307 tons of ore and gold worth \$257,357, and the latter \$466,146. The Headlight mine, at Carrville, is the principal deep mine and is equipped with a 250-ton mill and cyanide plant. Other mines are the Blue Jay, Golden Eagle, Deer Lick, Rams Horn, and Golconda. At Coffee are the Battle Peak, Gold Ridge, and Mule.

At Deadwood are the Brown Bear and Readjuster, the former being opened by long adits. The Globe is at Dedrick, while at Denny, Douglas City, Lewiston, Minersville, Quinby, and Trinity Center are numbers of small mines. The Alta Bert Dredging Co. has the most productive placer property. This at Trinity Center. At Weaverville is the well known Lagrange hydraulic mine. Other placers of importance are the Big East Fork hydraulic, at Dedrick; Browns Ranch hydraulic, Trinity Consolidated hydraulic, at Douglas City; Chapman hydraulic, at Junction City; Trinity Dredging Co., at Lewiston; Sykes hydraulic, at Trinity Center; and Five Cent mine of the Trinity Consolidated Hydraulic Mining Co., at Weaverville. In Trinity county, as in Siskiyou, there are no restrictions requiring the impounding of the mining debris, as these counties are outside the drainage basins of Sacramento and San Joaquin rivers, where the government restriction applies to this character of gravel mining on navigable streams. These details are given in a report recently issued by the U. S. Geological Survey, and were compiled by Charles G. Yale.

The Trinity Consolidated Mining Co. has started work on fitting up its placer mines for the season, and has employed all the available miners. Its properties consist of what are known as the Hupp and Union Hill mines.

TUOLUMNE COUNTY

(Special Correspondence.)—A 4-stamp mill, purchased from the owners of the Nervi mine, is being installed at the Sonnet mine, above Columbia, operated by R. C. Davis and associates. The long 8 by 8-ft. adit to drain the workings of the Springfield Tunnel & Development Co., near Columbia, has been driven 50 ft. during the progress of the work of installing the compressor and other machinery at the site. The working force will be greatly increased soon, when better progress will be made. A certificate showing that the Company has increased its capital stock from \$200,000 to \$500,000 was recorded in this county this week. It is reported that a body of high-grade ore has just been opened in the 500-level drift at the Dreisam mine, at Arastraville. The property is operated by James E. Conde, the owner. The Street mine, at Tuttletown, is being dewatered for inspection by T. J. Russell, who, with others, will resume operations at the property if satisfied with prospects. B. W. Rhay, G. A. Waddle, Robert Jameson, and John Brill, of Marysville, are developing a mining property on the App ranch, near Jamestown, and this week inspected operations to determine the advisability of conducting work on a more extensive scale. Some high-grade ore was recently uncovered in the Carlin mine, near Jamestown, operated by the Jamestown Exploration Co. A sufficient quantity of the ore is in sight, it is said, to insure the continuance of development operations. The property of the Cherokee Gravel Mining Co., situated at Cherokee, north of Tuolumne, is to be reopened for further development. The long adit started years ago will, it is understood, be driven to cut an old shaft, the bottom of which had reached a rich gravel deposit. Unable to handle the water which entered the shaft, the early-day miners were forced to abandon the undertaking before much gold was taken out. The owners of the property are confident of ultimate success, but considerable money will have to be expended in dead work before reward is theirs.

Sonora, December 6.

The Gold Ridge group of claims, locally known as the Jones' properties, situated a little northeast of the Shawmut mine, is being examined by W. H. Adams. The property was recently bonded by Henry T. Gage, ex-governor, of California, at a purchase price of \$60,000, with time privilege of payment.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Hendrie & Bolthoff, operating a property near Dumont, are grading for a 100-ton mill that is to be erected soon. A new boarding-house has just been completed. W. H. Barrick is manager. Shipments have been started from the Captain Jack property, situated on Ohio mountain. The smelting ore is worth \$40 per ton in gold, silver, and lead. J. R. Richards is

manager. Hayden & Co., leasing on the Young America, on Red Elephant mountain, are shipping ore that mills \$75 per ton in silver and lead. Work is being conducted through the White adit. Shaffer & Co., leasing on No. 14 level of the Gem mine on Seaton mountain, is shipping an average of 1000 tons of mill ore per month. The product is being consigned to the Newton mill. G. W. Ford has secured a lease upon 500 ft. of ground on the East Bellman vein. Operations will be prosecuted through the Central adit. Work was resumed this week on the Lake property, one of the former heavy producers of the district, and work was started last week on the Argus property, situated on Chicago mountain. The adit that has been driven 1100 ft. will be continued on into the hill. J. T. Mallalieu is manager. Rendahl & Co., leasing on the Anamosa mine on Columbia mountain, is making large shipments of 140-oz. silver ore. Stoping is in progress on a shoot that is 14 in. wide. R. D. Blair, owner of the Castle Rock property at Freeland, is doing development work. A new cross-cut has been started that is figured to undercut the shaft workings by 150 feet.

Idaho Springs, December 7.

GARFIELD COUNTY

On December 16, 38 miners were killed by an explosion of gas in the Vulcan coal mine at Newcastle. Relief work was rushed as soon as possible, but too late to save anybody. Two men, out of 40 on shift, escaped from an upper level of the mine.

PARK COUNTY

It is reported that the Mineral Park, Camp Bird, and Weber claims are to be opened in the spring. The Columbian is being worked under lease.

TELLER COUNTY (CRIPPLE CREEK)

The annual report of Stratton's Independence, Ltd., contains the following:

Ore treated, tons	130,110
Gold output	\$302,000
Profit	115,000
Ore sales on Company account, profit.....	67,000
Ore sales on lessees' account, profit	53,000
Dividends	120,000

Mine development opened no new ore-shoots, and lessees' production declined, and is likely to decrease. A working profit of \$7000 per month is all that is figured on for the future.

At the beginning of December the Roosevelt drainage tunnel was yielding 6700 gal. of water per minute. A new measuring weir is to be constructed at the portal. The Dexter shaft on Bull hill is down 1217 ft., and a station is being cut at 1200 ft. Lessees are shipping ore regularly to the Golden Cycle mill.

IDAHO

The total mineral production of Idaho in 1912 was \$21,816,390, according to E. W. Parker, of the U. S. Geological Survey. The increase over 1911 was \$3,374,845. Lead constitutes about 60% of the total mineral output of the state, the production for 1912 being valued at \$12,788,355, an increase of \$523,311 over that of 1911. About 94% of the refined lead came from the Coeur d'Alene district, in Shoshone county, the centre of the mining industry of the state. As a lead producer, Idaho ranks second among the states, Missouri being first. Second in importance in the mineral products of the state is silver, the value of which in 1912 was \$5,101,268, an increase of \$757,316 over the value in 1911. Shoshone county yields 91% of the silver output. The value of the gold produced in 1912 was \$1,381,214, against \$1,372,387 in 1911; that of copper was \$1,236,205, against \$644,117 in 1911; and that of zinc was \$959,479, against \$475,394 in 1911. Idaho also produced in 1912 non-metallic products valued at \$339,716, consisting of clay products, coal (lignite), gem materials, lime, mica, phosphate rock, salt, sand, gravel, sand-lime brick, and stone. The non-metallic resource of greatest promise is phosphate, large deposits of which occur in the southeastern part of the state and extend over into northeastern Utah and southwestern Wyoming. As the agricultural industries of the

Western states are developed this necessary fertilizer should become one of the important items in the mineral production of Idaho.

SHOSHONE COUNTY

The Stewart Mining Co. will pay a dividend of 10% on December 29. The land in the Pine Creek district is more valuable for mineral than for any other purpose, according to the decision of the federal land office at Coeur d'Alene in the case brought by the Constitution Mining Co. against H. Lester Gilliland, who filed a homestead claim on the property, the mining company protesting. The decision in part reads: "Without setting forth in detail the testimony as to the mineral character of the land, we find that the evidence is sufficient to show that the land embraced within the American Girl, Percy, Fred, Defender, Crescent, and Comet lode claims is more valuable for mineral than for any other purpose, and we recommend that segregation survey be ordered."

MICHIGAN

HOUGHTON COUNTY

Having to tram its ore over a long distance, the Champion Mining Co. has decided to install electric locomotives underground. Ten have been ordered and six have been delivered by the General Electric Co. Hardinge mills are being installed in the mill.

NEVADA

EUREKA COUNTY

The Buckhorn mill is complete, and will probably be started before the end of the year.

HUMBOLDT COUNTY

Ten carloads of ore, totaling about 350 tons, having a gross value of \$10,500, is shipped daily from Rochester to custom works. Rich ore has been opened in the Cole, and lessees are doing well.

The Kramer mine at Golconda has been sold for \$350,000 to J. T. Sullivan and J. Berger and others of San Francisco and Seattle. The property consists of six claims. S. H. Crittenden is surveying the mine.

LYON COUNTY

The Casting Copper orebody of the Nevada-Douglas mine continues to yield 130 tons per day of ore containing 8.5% copper. The development work for the past week has extended the orebody about 50 ft. in a southeast direction. It is extending on a flat dip into the limestone mountain with the ore remaining the same grade. Raises are being driven from the 200-ft. level to cut this ore on its dip.

LINCOLN COUNTY

The right of way for the new tramway of the Day-Bristol company is cleared, and grading for towers has been completed. This line will connect the mines on the Bristol side with the terminus of the Pioche-Pacific railway, on the other side of the ridge. The line is 9125 ft. long, has a rise of 300 ft. to the summit, then a fall of 900 ft. to the railway. A 15-hp. Alamo oil-engine will drive the ropeway, which has a capacity of 15 tons per hour. It is constructed on the Broderick & Bascom system.

NYE COUNTY

At Pioneer, the Pioneer Consolidated mill is in operation treating from 50 to 60 tons per day. During November, the following outputs were made:

	Tons.	Yield.	Profit.
Belmont	14,825	\$266,618	\$161,388
Jim Butler	1,500	7,153
Tonopah	12,011	220,775	137,470
West End	4,539	36,605

STOREY COUNTY

The annual report of the Ophir Silver Mining Co. contains the following information: The mine produced 4455 tons of ore yielding \$24.62 per ton, and there was 2227 tons of tailing treated at the cyanide plant. The total yield was valued at \$163,552. On No. 16 level the southwest drift was retimbered, and parts of the 1800, 2000, and 2300-ft. levels were repaired. Development was done on the East and Hardy veins at 1600 ft., but stopped through lack of funds.

An understore on a shoot of the Hardy vein at 2400 ft. yielded good ore. A fair amount of work was done on the 2500-ft. level. The cyanide plant treated 21,509 tons of tailing from nine different sources, yielding \$99,494. The cost of treatment was \$1.75 per ton. Average recoveries were 92.91% of the gold, and 75.01% of the silver, based on actual bullion produced.

WHITE PINE COUNTY

The safety department of the Nevada Consolidated reports 72 accidents during November, 34 at the mines, 17 in the mill, and 21 at the smelter and shops. There was only one death, a man being crushed by cars at Copper Flat.

OREGON

JOSEPHINE COUNTY

(Special Correspondence).—At the Oriole mine, in the Galice district, a large number of men is busy with deep development and erecting a new 10-stamp mill. J. C. Mattison is manager. In addition to the reduction plant, concentration and cyanidation is also to be used. Power will be supplied by water and steam, and the mill will be crushing ore within 60 days. As the ore of the Oriole is soft and friable, the 10 stamps will easily reduce from 40 to 50 tons per day. The Oriole has now a mile of underground workings, and is one of the best developed quartz mines in the Galice district. In opening the property a considerable quantity of shipping ore was extracted, and this has been shipped to Tacoma for treatment. There is enough profitable ore in reserve to keep the new plant running for a considerable time.

The Silver Creek district, in the western part of the county, is showing unusual activity this season, both in quartz and placer mining. F. L. Mangum, manager of the Old Glory, is employing men on development through the winter. The Old Glory is a large low-grade proposition, containing gold, copper, and silver, gold being the predominating metal. F. V. Metts, owner and manager of the Metts hydraulic mine, of Silver creek, reports that his property has been in steady operation for some time, and that the present season promises to be an excellent one, not only for the Metts, but for many of the placers of western and southern Josephine county. It is figured that the falling off of the surface gold yield, as shown by last year's figures, will more than be made up this season, because of the extended run and richness of ground on which many mines are operating.

Deep snows are putting a check on the development of claims on the Siskiyou range, particularly in the upper Sucker Creek districts above Holland, where a number of rich discoveries were made late in the fall. Work on these will be resumed in the spring. The snow is proving of great benefit in maintaining a steady water supply for the placers, and assure an extended run in the spring.

Grant's Pass, December 20.

SOUTH DAKOTA

FALL RIVER COUNTY

(Special Correspondence).—The Ardmore Oil Co., at Ardmore, started well No. 1 on November 1. In the neighborhood is some oil seepage and the characteristic shales of the neighboring Wyoming fields of Salt Creek and Lander.

Ardmore, December 15.

LAWRENCE COUNTY

While the gold production of the Black Hills district of South Dakota is smaller for 1913 than for the previous year, economic results, measured in dividends, are the greatest in the history of the area. Among the dividend payers the Homestake heads the list, with a total distribution in 1913 of \$2,167,620, as against \$1,310,400 in 1912. Wasp No. 2 paid \$55,000, and a large number of close corporations and small operators and lessees accumulated profits which have not been made public.

Considerable new work is planned for next year by the Homestake company, among the most important of which will be an auxiliary steam-driven electric-generating station and a new hoisting engine for the Old Abe shaft. Both of these will be driven from a centrally placed boiler

plant. The new hoisting equipment will be the finest in the Black Hills, and will be capable of handling material from a depth of 5000 feet. It will be installed at the Old Abe 5-compartment shaft, which has recently been equipped with an electric pumping system, a most complete installation with all units in duplicate. With the new hoist in operation skips will replace the cages so long used for hoisting ore at this property. It is estimated that improvements contemplated for 1914 will cost nearly a quarter of a million dollars. The Wasp No. 2 operated 8 months and 20 days in 1913. The property was closed during March, owing to cold and stormy weather, and on October 20 a shortage of water forced a suspension of work for the balance of the year. The Golden Reward mill at Deadwood was operated continuously at full capacity through the year. The Company owns a large territory in the Bald Mountain district. A good area of this property is operated by lessees, the Company milling the ore for them. The Company will soon erect a new mill, but whether it will be at the Astoria mine, where a large orebody has been developed, or at Deadwood, has not been decided. The Astoria ores differ materially from anything previously found in the district, and to treat them a Wedge oil-fired roasting furnace has been erected. Some tests have been made, but the plant is not now in operation.

PENNINGTON COUNTY

(Special Correspondence).—At Keystone, mica and the lithia minerals are being mined. Regular shipments of scrap mica are being made from a number of properties in the district, and the present good market promises a continuation of activity. The Etta mine in 1913 produced the lithia minerals, spodumene, lepidolite, and amblygonite. They are shipped to Jersey City for treatment. The Continental Copper Co. resumed work on its property late in the fall. The 800-ft. shaft is to be continued. The Otho Co., at Spokane, is erecting a mill which it is hoped to have in operation early in 1914. The Gold King company in the Rohford district, did considerable development work, with encouraging results.

Keystone, December 15.

UTAH

SUMMIT COUNTY

On December 23, the Silver King Coalition Mines Co. of Park City paid 15c. per share, making a total of \$2,347,385 by the present Company, and \$13,022,385 by this and the old company.

WASHINGTON

FERRY COUNTY

Ore mined in the Republic district is the largest since it was opened. Increased tonnages are coming from the Quill, Surprise, Lone Pine, Ben Hur, and San Poll. On the 600-ft. level of the Ben Hur, \$9.20 ore has been opened.

OKANOGAN COUNTY

Rich gold-bearing ore has been discovered at Chesaw, 125 miles northwest of Spokane, chiefly at the Eagle and Reco properties.

STEVENS COUNTY

A small furnace was blown-in on December 14 at the Copper King mine, near Chewelah, to determine whether the ore was self-fluxing or not.

WYOMING

FREMONT COUNTY

(Special Correspondence).—The American Fireproofing & Mining Co. has been organized to operate some of the partly developed gold claims in the Lewiston district. Charles M. Hampson, of Denver, has been retained as consulting engineer, and has just completed a series of tests to determine the best treatment of this peculiar ore. While the gold is to all appearances free, it has been ascertained that amalgamation will save only 10% of the content, yet there is so much coarse gold that it is impracticable to cyanide the entire product of the mine; therefore it is probable that a combination treatment will be resorted to. The ore will be crushed to 12 mesh and amalgamated, the pulp reduced to 150 mesh, and the continuous agitating

cyanide process will be adopted. Over \$1,000,000 in high-grade ores is estimated to be available for milling. Much of the ore in the Bobtail claim will average about \$100 per ton, and tests show that 97% can be saved by the process mentioned. A small mill will be at once erected with a capacity of 50 tons per 24 hours, and plans at once commenced for a larger plant. A hoisting and compressor plant is already on the property.

Denver, Colorado, December 12.

CANADA

BRITISH COLUMBIA

Zinc ore and concentrate from the Slocan district in November was 2773 tons, and a total of 6545 tons for the 11 months. The Queen Victoria mine, near Nelson, shipped 25,946 tons of ore to the Greenwood smelter during the same period. A dividend of \$2 per share has been declared by the Consolidated Mining & Smelting Co., which operates several mines in the province and a smelter at Trail. Distributions during 1913 totaled \$464,352. High-grade silver-lead ore has been opened in the Treasure Mountain mine, in the Leadville district.

ONTARIO

(Special Correspondence.)—The Associated Gold Mines of Western Australia has taken an option on the North Thompson, and, when the Crown Reserve allowed its option on the Vipond to lapse, the Associated took an option on the Vipond. On the North Thompson, two diamond-drills are at work, and a shaft is being sunk on the extension of one of the rich Vipond veins, that in the shaft is showing considerable free gold. The Nipissing Mines Co., which has an option on the St. Paul, Hewitt & Hull claims in Bartlett and McArthur townships, has completed new camps, and is going ahead with the preliminary development of the above claims. The Lally gold mines, in Turnbull township, has finished the construction of a winter road from Sandy Falls, and as soon as the weather is suitable, will

CROWN RESERVE MINE, COBALT; KERR LAKE, WHICH HAS BEEN DRAINED, IS IN THE FOREGROUND.

take in machinery and supplies for continuous development work during the winter months. The Wittsky-Cling Syndicate, which owns claims in Whitesides township, has commenced the construction of a winter road to its claims, which are about fifteen miles west of Bristol Landing, on the Mattagami river. A 50-ft. shaft has been sunk on a vein traced about 700 ft., and which shows gold content varying from \$4.90 to \$63 per ton.

The extraordinarily mild and very unseasonable weather is retarding development work in the outlying districts, owing to the impassibility of the trails. The Mattagami river is clear of ice again, and almost all the snow has disappeared.

Mattagami Helghts, December 4.

The Dome milll treated 13,820 tons of ore in November, yielding gold worth \$121,100. This makes a total of 90,860 tons and \$829,202 since April. Diamond-drilling on the 200-ft. level of the Hollinger has proved an extension of the main orebody. During December the Company paid two dividends totaling \$180,000.

The Kirkland Lake Proprietary, Ltd., has been formed in London with a capital of £200,000. C. A. Foster, of

Haileybury, is largely interested. The Teck-Hughes Co. has been acquired by the Company, and other transactions are pending. The Hurricanaw gold-mining district is near Keniwisik, 55 miles south of the Transcontinental Railway. People who have recently returned from there, speak well of its possibilities.

COLOMBIA

Withdrawal of the concessions of the Pearson syndicate has opened a wide oil territory to other interests, and several American syndicates are already in the field. One of them is headed by William Potts, of California. Another, the Colombian Land & Industrial Co. of New York, has secured large holdings in the Magdalena valley. The American Colombian syndicate, headed by C. E. Holaby of New York, is buying land, as are also the Colombia Syndicate, Ltd., the Standard Oil Co., and the Caribbean Oil Co. Both public and private lands are available for development.

The General Development Co. of New York has taken an option on a large area of alluvial ground on the Neché river south of Pato.

COSTA RICA

The Abangarez Gold Fields company reports as follows for October:

	October.	Year to date.
Ore crushed, tons	5,958	54,435
Tailing leached, tons	540	5,332
Slime treated, tons	4,970	44,759
By amalgamation	\$ 9,356	\$108,133
By cyanidation	40,516	366,017
Total bullion	\$49,872	\$474,151
Cost of operation, marketing, and administration	46,986	500,889
Profit	\$ 2,886	*\$ 26,738
Betterment expenditure	\$5,587	\$66,767
*Deficit.		

During the same period of 1912 the deficit was \$92,370, and \$194,769 was spent on betterments.

KOREA

The Oriental Consolidated Co. reports the following results in October, 1913:

Stamps working	240
Time, days	27.4
Ore crushed, tons	27,178
Gross receipts	\$137,626
Operating costs	88,287
Operating profit	\$ 49,339
Cost of improvements	7,545
Net profit	\$ 41,794

MEXICO

SONORA

The Tigre Mining Co., operating at El Tigre, reports the following output during November:

Stamp-mill crushed, tons	5525
Cyanide plant treated, tons	6942
Revenue from shipping ore, concentrate, and bullion	\$127,675
Total expenditure	77,685
Estimated profit	49,990

On December 4 bonds worth \$23,000 were purchased, leaving \$49,600 outstanding. On December 20 a dividend of 6c. per share was paid.

At La Cobrizza mine, at Noria, about 100 miles south of Nogales, a furnace of 150-ton capacity will be blown-in early in January. A 100-ton concentrating plant will also be erected to treat the low-grade copper-silver ore. Fifty men are employed under Robert Mitchell.

The following ore shipments were made through the 'port' of Agua Prieta during November: Nacozari, 13,491 tons; El Tigre, 214; Swamp Queen, 8; La Sonora, 101; La Alemana, 48; San Carlos, 10; San Pablo, 18; Monte Cristo, 10; La Union, 25; Good Enough, 19; Crestonclito, 4; Santa Rosa, 41; Ventana, 42; and El Vaguero, 27; a total of 14,058

tons. El Tigre shipped 62 bars of gold and silver bullion weighing 9748 lb. Estimated values, in Mexican money, of ores and bullion were: copper, ₡2,119,400; silver, ₡806,700; and gold, ₡259,600; a total of ₡3,185,700. The Greene Cananea has paid a dividend of \$1 per share. Four furnaces are running and a total of 2500 men are employed in the district.

NICARAGUA

At the annual meeting of Camp Bird, Ltd., in London on November 17, some details were given regarding this Company's interests in the republic. A 40% interest has been accepted in a syndicate of the Canadian Agency, Ltd., of New York. The properties have been examined on two occasions by the Camp Bird company's engineers and have been favorably reported on by them, and their reports have been entirely endorsed by R. J. Frecheville. The properties consist of five groups of mines in Nicaragua, known as the Bonanza, Mars, the Lone Star, Siempre Viva, and Colona. The Bonanza and the Mars have mills and plant of 75-ton daily capacity and have, during the past 10 years, produced

MAP OF NICARAGUA.

over 200,000 tons of ore at a yield of about \$1,920,000. Operations, being handicapped by lack of funds and by expensive transportation, have only been on a small scale, the light equipment not being sufficient to treat the hard material after exhaustion of the soft surface ores. Orvil R. Whitaker was commissioned by the directors to make an exhaustive examination of these properties, and after visiting the properties with a staff of engineers, he strongly recommends their purchase and further development. Mr. Whitaker reports that the aggregate length of known ore-shoots in these groups is 20,500 ft., the average width of the veins being about 15 ft., and that there are now in sight above drainage level approximately 2,400,000 tons of positive and probable ore, all of which can be mined by means of open-cuts and adit levels, of an average grade of \$6.66 per ton, from which a profit of \$5,000,000 should be obtained. There is no payment for working the bond and lease of the claims for a year, only a rental of \$6000 per month. Provided all titles are clear, the syndicate must pay \$369,000 at the end of the first year, and if all is satisfactory the balance of \$753,600 is to be paid a year later.

PHILIPPINE ISLANDS

Australian dredging companies in the Philippines promise well, according to *The Bulletin*, Sydney. The Gaumus company is getting \$38,000 worth of gold per month from gravel worth from 48 to 60c. per yard. The Philippines Dredging Co. has 1000 acres, and is working one small dredge on 48c. ground. Three other dredges are building to work gravel worth 24c. per yard. Excellent prospecting work has been done by the Umeari company, which has 1600 acres on the Umeari river lower than and adjoining a Manila company which is getting 96c. per yard.

Personal

R. G. HALL is at Boston.

WILLIAM HAGUE is in New York.

SPENCER C. BROWNE, Jr., is in San Francisco for the holidays.

J. B. TYRRELL is in England, but is expected home before Christmas.

A. D. WILCOX, of Goldfield, is ill at the Lane hospital in San Francisco.

H. P. HENDERSON has removed his offices to 66 Broadway, New York City.

G. A. DUNCAN has gone to Santa Monica, California, from Nelson, Nevada.

C. W. VAN LAW, of Pachuca, Hidalgo, Mexico, is now in Boston, Massachusetts.

A. D. SPROAT, formerly of Chillicothe, Ohio, has moved to San Antonio, Texas.

C. B. WHITWELL is examining the Red Cross mines, at Dobbins, Yuba county, California.

FRANK R. PORTER, owner of the Porter Placer Co., at Grass Valley, has gone to Pasadena, California.

JESSE J. MACDONALD passed through San Francisco this week on his way to Los Angeles from Garfield, Utah.

LOUIS EMANUEL is now superintendent of the smelter of the Arizona Consolidated Copper Co., at Humboldt, Arizona.

F. G. FARMAN and H. E. HALL have formed a partnership to engage in general mining and consulting engineering work, with offices at 220 West 42nd street, New York City.

W. G. PAGE, president of the Kelsey Mining Co., of San Francisco, has been visiting Portland and making arrangements for the operation of a placer property in Curry county, Oregon.

JOHN R. RUTHERFORD has resigned his position on the engineering staff of the Hollinger Gold Mines, Porcupine, to accept a position as superintendent at the Motherlode Gold mine, Sheep Creek, British Columbia.

GEORGE S. BAILEY, superintendent for the Anaconda Gold Mining & Smelting Co., has been appointed by Judge E. K. PENDERGAST, of the Superior Court, receiver for the Republic Mines Corporation, controlled by J. L. HARPER.

J. M. CALLOW, of the General Engineering Co., of Salt Lake City, Utah, is at Superior, Arizona, starting work on the construction of the concentrator for the Magma Copper Co. at that point. He expects to return to Salt Lake City shortly before Christmas.

PETROLEUM producers and others interested in the oil industry are invited to attend a meeting of the California section of the American Chemical Society in the Committee Room of the San Francisco Chamber of Commerce, Merchants Exchange building, Monday, December 29, at 8 p.m. The meeting will be addressed by Irving C. Allen, of the United States Bureau of Mines. Plans for a petroleum exhibit at the Panama-Pacific Exposition will also be discussed.

Obituary

JOHN O. HARRON, president of Harron, Rickard & McCone, of San Francisco, died on December 19, following an operation for appendicitis. Mr. Harron's death removes one of the notable figures in the Western machinery world. He commenced his business career as an apprentice at the Union Iron Works, and later became identified with the firm of Parke & Lacey, at that time one of the prominent machinery concerns of San Francisco. His advancement was rapid, and at the time of the death of B. P. Lacey, in 1901, Mr. Harron had become vice-president and general manager. He then associated himself with the late Thomas Rickard and A. J. McCone, and formed the firm of Harron, Rickard & McCone to take over the business of Parke & Lacey, under which name the business is still conducted. Mr. Harron was 54 years of age and left a widow and one son.

The Metal Markets

LOCAL METAL PRICES

San Francisco, December 24.

Antimony.....	10-10½c	Quicksilver (flask)	\$40

Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 24.—The copper market is stronger and an increased demand is being experienced. Standard is quiet, with December to March offered at 14.37½. A change for the better has taken place in the lead market, while spelter is quiet with quotations ranging from 5.25 to 5.50. The Chino dividend of 75c. per share will be paid on December 31, and a dividend of 37½c. will be made by the Ray Consolidated company at the same time. The share market is greatly improved and an upward tendency is to be seen in the majority of the stocks. Shares sold in New York on December 23 were valued at \$2,476,000 as against \$1,454,000 for the same day one year ago.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending
Dec. 18.....	57.75
" 19.....	58.00
" 20.....	58.00

June	61.29	59.03	Dec.	63.38

The outstanding feature of the week ended December 4 was the necessity for the Indian Specie Bank to close its doors. The huge speculations of this bank have been a source of much general uneasiness for some three years past, and the burden of carrying the large stock involved has been exceedingly heavy to those concerned. Negotiations have just been completed by which the entire unrealized stock, both in actual silver and also in the form of contracts for forward delivery, formerly held here by the Indian Specie Bank, has been acquired by a strong London syndicate. This step will prove of immense benefit in relieving apprehensions as to further disturbance of the silver market, as a consequence of recent events.

A sharp fall in prices during the week, according to Pixley & Abell's report, brought in large covering orders from China and India on December 2, and quotations advanced to 26½ and 26¾d., respectively. Since then, although business has been restricted, prices have recovered a little further. At the close the market was quite steady, supplies being small, while bears show a disposition to cover their commitments.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

The copper market was almost featureless during the week ended December 20. Most of the recent buying had been

on European account, but by December 15 even the European purchasers disappeared from the market. Large sellers were asking 14½c. delivered to the consumer, 30 days, but without any large sales. On December 16 and 17 buyers had completely deserted the market. On December 18 small European orders were placed, but none of any importance.

The following figures of German consumption of foreign copper for the first ten months of 1913 have been supplied by L. Vogelstein & Company:

	Tons.
Imports	193,457
Exports	8,076

Consumption

The consumption for the same period of 1912 was 169,551 tons. Of the 1913 total, 167,015 tons was imported from the United States.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

MINERAL PRODUCTION OF WYOMING

The mineral product of most importance in Wyoming is coal, the value of which represents nearly 90% of the total output of the state. The value of the products of all the mines in 1912 was \$13,374,088, of which coal, 7,368,124 short tons, represented \$11,648,088. The value of the other mineral products in 1912 was about \$1,700,000. The development of the extensive phosphate deposits in the southwestern part of the state gives promise of establishing an important industry there in the future.

MINERAL PRODUCTION OF TEXAS

The total value of the mineral production of this state increased from \$18,798,837 in 1911 to \$22,797,015 in 1912, an advance of \$4,000,000, two-thirds of which was due to the larger production of petroleum and natural gas, according to the U. S. Geological Survey. Details are as follows:

Oil, barrels	11,735,057
Coal, short tons	2,188,612
Cement, barrels	1,762,780
Value of clay products	\$2,886,068

MINERAL PRODUCTION OF MICHIGAN

The total value of all minerals in 1912 was \$80,062,486, against \$65,275,324 in 1911, according to the U. S. Geological Survey, which publishes the following:

Iron ore, long tons	12,717,468
Copper, pounds	218,138,408
Copper since 1810, pounds	5,200,000,000
Salt, barrels	10,271,715
Cement, barrels	4,000,000
Sand and gravel, short tons	2,185,165
Gypsum, short tons	384,297

MINERAL PRODUCTION OF GERMANY

The output in 1912 was as follows, according to a recent report:

Employees	755,888
Fatal accidents	1,777
Total mineral output, metric tons	246,623,289
Total value	\$524,763,000
Hard coal, tons	165,303,784
Brown coal, tons	65,803,959
Brown coal used in manufacturing briquettes, tons	55,000,000
Asphalt, tons	21,241
Petroleum, tons	87,443
Iron ore mined, tons	5,238,766
Zinc ore, tons	647,081
Lead ore, tons	135,366
Copper ore, (Mansfield Copper Co., 879,695 tons) tons	967,785
Manganese ore, tons	92,474
Sulphur ore, tons	233,397
Mineral salts, (potash, etc.) tons	8,071,114

Company Reports

MOUNT LYEELL MINING & RAILWAY COMPANY, LTD.

This well known Company operates copper mines, railways, smelters, and pyrite deposits in Tasmania, and superphosphate works in Victoria, South and Western Australia, under the general management of Robert C. Stiecht. The report covers the half-year ended September 30, 1913.

After the disastrous fire and flooding of the North Lyell mine, a return to the usual scale of mining operations was reached toward the end of the period. There are at present 1040 men employed in the mines, and all workings and equipment are in good condition. Development covered 2065 ft. At the Mt. Lyell property both surface and

	Copper,	
	Tons.	%.
Mt. Lyell, available for open-cut work.....	408,101	0.58
Mt. Lyell, available for underground work.....	1,794,234	0.52
North Lyell	1,086,112	6.00
The Mt. Lyell ore contains 0.0275 oz. gold and 1.96 oz. silver, and the North Lyell 0.005 oz. gold and 1.33 oz. silver per ton.		
At the smelter, an average of 2.3 blast-furnaces were in operation, resulting in the following production:		
Mt. Lyell ore, tons	93,470	
North Lyell, tons	36,255	
Lyell Comstock, tons	8,544	
Metal-bearing fluxes, tons	4,346	
Flue-dnst, tons	3,191	
First matte, tons	3,244	
Converter slags, tons	4,395	

MT. LYEELL SMELTER AT QUEENSTOWN, TASMANIA.

In the left corner is the converter plant; in the centre is No. 1 blast-furnace, now out of commission; No. 2 blast-furnace plant is on the right, and in the foreground is the granulated slag dump, which now covers the whole area where the houses are shown on the right.

underground work was continued without interruption on five overburden and three ore benches. No new development was carried out during the term, such not being necessary.

The South Lyell pyrite deposit, which is distinct from the parent mine, is being worked as one with the latter. Operations were confined to development, and, incidentally, some pyrite was recovered. This is lower grade than the Mt. Lyell ore. Prior to resuming stoping in the North Lyell, a great deal of work was rendered necessary by the flooding of the mine. New passes were made and diamond-drilling done. Pump-houses at 700 and 1000 ft. were rebuilt in concrete and steel. The Lyell Tharsis mine supplied silicious metal-hearing flux for the smelters. Ore extraction was carried on four levels in the Lyell Comstock mine, and a large amount of development was done. At the Crown Lyell nothing special was done. The Chester mine, in the North Pieman district, supplied 4400 tons of pyrite for the superphosphate works. Ore reserves are as follows:

Converter linings, tons.....	425
Total	153,869
Blister copper, pounds	5,470,080
Gold, ounces	4,050
Silver, ounces	187,097
Revenue from blister copper and superphosphates.....	\$1,180,000
Revenue from railway	81,600
Profit after paying all expenses	201,000
Surplus	2,300,000
Good progress is being made with the Lake Margaret hydro-electric power scheme, and \$180,000 has been spent so far, and contracts for machinery have been let amounting to \$307,000. Large tests, with the Minerals Separation process, on ore from the Comstock mine have given good results, and further work is under way in this connection. Rainfall in the various districts where the Company operates varied from 118 to 131 wet days with 43 to 65 inches. Including all claims for compensation, the North Lyell disaster cost \$202,000.	

MOUNT ELLIOTT, LIMITED

This Company operates in Queensland, Australia, and the report deals with the period ended June 30, 1913. The smelter was shut down for 135 days during the year, but results for the remainder of the time were as follows:

Ore reserves:

Ten per cent ore, tons	44,500
Three per cent ore, tons	350,000
Ore smelted, tons	41,633
Copper produced, pounds	10,373,440
Gold, ounces	8,757
Silver, ounces	7,285
Net profit	\$ 682,000
Brought forward from 1911-12	422,000
Dividends paid	965,000
Carried forward to 1913-14	129,000
Depreciation, written off	67,000

HAMPDEN CLONCURRY COPPER MINES, LTD.

This Company operates at Cloncurry, Queensland, Australia, and the report covers the half-year ended August 31, 1913. Development in the Hampden mine, on the 350-ft. level, has opened 161 ft. of pyritic ore containing from 6.5 to 21% copper, with a further extension. Its width is from 8 ft. upward. Operations resulted in the following:

Ore reserves, tons	255,000
Copper content, per cent	10
Ore smelted, tons	24,744
Copper produced, pounds	5,815,040
Gold, ounces	818
Silver, ounces	24,457
Operating profit	\$346,600
Net profit, including amount from previous term	461,000
Depreciation	39,000
Carried forward to next term	422,000

OROVILLE DREDGING, LIMITED

In this journal of October 25 was published the report of the above Company, dealing with operations to January 31, 1913. The present report covers the period up to July 31, 1913. The profit and loss account shows that the California properties returned \$162,806 during the full twelve months of the fiscal year just closed, after deducting all expenses, including the expenses of administration of Oroville Dredging, Limited. Of this amount, \$59,762 was set aside as a reserve for dismantlement of dredges, and \$103,044 was transferred to surplus, which was \$402,645 at July 31.

The report of W. P. Hammon, general manager, for the six months ended July 31, contains the following: The California units comprise the Boston & Oroville Mining Co., Boston & California Dredging Co., Oroville Gold Dredging & Exploration Co., Bear River Mining Co., and Boston Machine Shop Co., which are all situated in Butte, Yuba, and Placer counties. At February 1 there were five dredges working, but at the end of the period there were only three, on areas west of the Feather river at Oroville. A total of 1,612,519 cu. yd. of gravel, equal to 30.38 acres, was handled, the depth of banks being 31.1, 36.2, and 38.1 ft., respectively. The yields were 10.88, 11.11, and 7.41c. per yard from these depths, giving a total gold output of \$173,458. Costs were 6.78c. per yard dredged. Averages per acre were: 53,078 cu. yd., \$5709 yield, \$3604 expenditure, and \$2105 net profit.

The report gives details of the Pato dredge, in Colombia, recent returns from which were given in the news columns of this journal of December 13. During July the boat crossed and recrossed Pato creek, and handled as high as 5446 cu. yd. per day. From February 28 to July 31 the boat averaged 15.08 hr. per day, treated 2483 cu. yd., attacked a bank 24.4 ft. deep, and yielded 14.79c. at a cost of 12.49c. per yard. The net revenue was \$10,374.

Net imports into Germany for the 10 months of 1913 were £16,325,000. Gold reserves in India total \$30,000,000 out of a total arrival of over \$146,000,000.

COMPARATIVE STATISTICS OF LEAD, COPPER, SPelter, TIN, ALUMINUM, NICKEL, QUICKSILVER, AND SILVER. Metallbank und Metallurgische Gesellschaft, Frankfurt on Main, July 1913. P. 109. An annual compilation of figures of the highest value.

LONG SAULT RAPIDS, ST. LAWRENCE RIVER. By Arthur V. White. Commission of Conservation, Canada. P. 384. Ill., index, maps. Ottawa, 1913. An enquiry into the constitutional and other aspects of the project to develop power from the rapids.

CYANIDATION IN THE MERCUR DISTRICT OF UTAH. By L. O. Howard. Reprinted from the *Salt Lake Mining Review*. October 1913. P. 64. Ill. This series of articles gives an interesting account of the history of the properties owned by the Consolidated Mercur Co. and the development of the methods of ore treatment at Mercur. It was at the Sunshine mill that the difficulty of treating the slime first inspired George Moore with the idea of a vacuum filtration system, which was afterward used most successfully. With the dismantling of the Consolidated Mercur plant, now under way, this great property appears to have ended its long and profitable existence.

DETAILED REPORT ON CADELL, WAYNE, AND LINCOLN COUNTIES, WEST VIRGINIA. By C. E. Krebs and D. D. Teets, Jr. P. 483. Ill., index. West Virginia Geological Survey, 1913. Also a case of 9 maps, covering the soils, topography, and geology of each county separately. In addition to the description of all geologic features of the counties in question, the geologic maps give the structural contours on the Pittsburgh coal horizon, as also the location of the anticlines and synclines, showing their relations to the several oil and gas pools of the district. The soil maps and reports of the experts of the U. S. Department of Agriculture covering this great agricultural and tobacco region of the state should prove of especial value to the agricultural and horticultural interests. Price, with case of maps, delivery charges paid by the Survey, \$2. Extra topographic or geologic maps, 25c. for each county.

DETAILED REPORT ON MARION, MONONGALIA, AND TAYLOR COUNTIES, WEST VIRGINIA. By Ray V. Hennen and David B. Reger. P. 844. Ill., index. West Virginia Geological Survey, 1913. See notice above.

INGERSOLL-RAND PRODUCTS. Vest-pocket size, 2 3/4 by 4 in., cloth bound. P. 140. Ill., index. The Ingersoll-Rand Co., New York, 1913. This is an extremely useful little publication, issued by a firm well known throughout the world. The book contains the following data: steam, electric, and gasoline-driven air-compressors, with details of cylinders, valves, capacity, and space occupied; auxiliary apparatus for compressors; Cameron steam pumps for all purposes; machine-drills for mines; drill-sharpening machines; air hammers; uses of compressed air, density of gases, and considerable useful information.

Book Reviews

STRUCTURAL GEOLOGY. By C. K. Leith. P. 169. Ill., index. Henry Holt & Co., New York, 1913. For sale by the *Mining and Scientific Press*. Price \$1.50.

In this small book are brought together in convenient form data previously available only in separate reports and documents. The attempt is made to relate structural features from the genetic viewpoint and to get away from the old way of thinking of fractures, faults, flow structure, schistosity, and similar features as individual and unrelated. The geologists who have grasped the relations of these phenomena find it possible many times to use one to uncover others and in the practical work of determining structure in areas where the latter is complicated, as is usually true where ore deposits occur, the method proves extremely fruitful. The book serves a useful purpose and should be widely used.

HYDRAULIC TURBINES. By R. L. Daugherty. P. 151. Index. McGraw-Hill Book Co. For sale by the *Mining and Scientific Press*. Price \$2.

This work is intended rather for hydraulic turbine operators than for the designer or hydraulic engineer. It is recognized by the author that as the use of the turbine increases, it is desirable that men in charge of hydraulic turbine power-houses should have at least a fair working knowledge of the characteristics of the machinery that they operate. The data given are therefore chiefly fundamental, and while they may not throw any additional light upon the subject as understood by engineers and turbine designers, at the same time for students and power-plant operators, this work will be especially useful, as the author has endeavored to prepare the text in such a way as to make it easily understandable by men who have not necessarily had the benefits of a technical training.

THE MINERAL INDUSTRY DURING 1912. Edited by Charles Of. P. 1090. Ill., index. McGraw-Hill Book Co., New York, 1913. For sale by the *Mining and Scientific Press*. Price \$10.

The twenty-first volume of 'Mineral Industry' is the second one edited by Charles Of, and is similar to its predecessor. The articles descriptive of the numerous mineral industries with statistics of production, were contributed by 73 writers, among whom are noticed many well known college professors, mining engineers, and geologists. The articles on coal appear to have been written principally by state Coal Mine Inspectors. There is a reasonably complete bibliography of articles upon general mining and engineering topics which have appeared in the engineering journals during the year, in addition to the bibliographies attached to the regular articles in this volume. The number of special chapters is smaller than usual, but the article on 'Geology Applied to Mining,' by C. F. Tolman, Jr., is of timely interest. R. H. Richards contributes an exhaustive chapter on the 'Progress in Ore Dressing and Coal Washing.' The volume is an excellent and useful book of reference on account of the large amount of carefully compiled statistics which it contains.

THE AMERICAN FERTILIZER HANDBOOK. P. 352. Ware Bros. Co., Philadelphia, 1913. For sale by the *Mining and Scientific Press*. Price \$1.

At first thought fertilizers may seem somewhat out of the field of mining engineering, but the reverse is actually the case. The production of the raw materials for phosphate fertilizer manufacture involves interesting mining problems. The utilization of the sulphurous fumes of copper smelters for the production of sulphuric acid, to be utilized in fertilizer manufacture has been practised successfully in Tennessee and California, while the production of potash salts in this country is a subject of keen interest at the present time. As a result many metallurgists and mining engineers have a lively interest in fertilizers, and all such will find in this convenient hand-

book a mine of useful statistical data, as well as valuable technical articles on the fixation of atmospheric nitrogen, production and use of cyanamide, potash salts, and fertilizers, the occurrence and mining of potash deposits, the manufacture and utilization of sulphuric acid, and a great variety of related matters. The tabular matter contained in this volume is of exceptional value to anyone whose interests touch on these fields. A classified directory of fertilizer manufacturers and of firms engaged in allied lines of business completes the work.

A TREATISE ON PETROLEUM. In three volumes. By Sir Boverton Redwood. J. B. Lippincott Co., Philadelphia. P. 1198. Bibliography. Index. For sale by the *Mining and Scientific Press*. Price \$15.

This is the third edition of this standard work, the first having appeared in 1895. With the petroleum-producing world as a field, some idea may be obtained of the monumental labor involved in the preparation of a work of this character. This is no mere reprint of a previous edition, as the entire text has been revised, rewritten, and added to, bringing the subject-matter up to present-day conditions in the oil industry. The first volume is divided into sections as follows: Historical Account of the Petroleum Industry; Geological and Geographical Distribution of Petroleum and Natural Gas; Physical and Chemical Properties of Petroleum and Natural Gas; Origin of Petroleum and Natural Gas; Production of Petroleum, Natural Gas, and Ozokerite. The second volume covers: Refining of Petroleum; Shale Oil and Allied Industries; Transport, Storage, and Distribution of Petroleum; Testing of Crude Petroleum, Petroleum, Shale-Oil Products, Ozokerite, and Asphalt; and the Uses of Petroleum and Its Products. The third volume covers: Statutory, Municipal, and Other Regulations Relating to the Testing, Storage, Transport, and Uses of Petroleum and Its Products; Statistical Appendix; Marine Transport of Petroleum; Import Duties Levied in the United States; Petroleum and the Thames Conservancy. It is impossible to do justice in a limited space to a work of this character, as the book itself must be seen and read to be appreciated.

GOLD DREDGING. By T. C. Earl. P. 208. Ill., maps, index. E. and F. N. Spon, Ltd., London, 1913. For sale by the *Mining and Scientific Press*. Price \$8.

This is a little book on a big subject made attractive by its numerous instructions. The author has evidently attempted to write a simple work for the use of mining investors and company directors who wish to inform themselves somewhat concerning gold dredging without being bothered with too many details and technical terms. In this respect the book may be useful, although to the experienced engineer it will appear too sketchy, if not altogether superficial. Such subjects as 'Reporting on Dredging Areas,' 'Cost of Dredges,' and 'Working Costs' are dismissed with a single page, but the chapter on 'Fields for Dredging' is 65 pages in length. In many respects this last chapter is the most interesting in the book, as it gives short accounts of all of the principal gold-dredging areas in the various countries of the world, together with descriptions of the different dredges working and tables giving the gold production, yardage dug, and similar figures. The data are given in order "to attract the investor in gold dredging and induce him to investigate grants on new and partly unknown fields." Mr. Earl is apparently a most patriotic New Zealander, and a large part of his book has to do with New Zealand dredges and dredging practice, but his figures speak eloquently in favor of the California dredge. For example, he states that in New Zealand in 1911 one hundred boats dug 14,000,000 cu. yd., and recovered £312,500 worth of gold; while in California 61 boats dug 65,000,000 cu. yd., and recovered £1,635,416 worth of gold. The average working costs are given as 1.71d. per cubic yard in New Zealand and 1.82d. in California, but there is always a doubt as to the accuracy of New Zealand figures, because bank measurements are not the rule there as they are in California. The author gives little evidence of any great amount of experience or technical knowledge of the subject. Like most attempts at a popular work on a technical subject, it is a disappointment.

Recent Patents

1,072,753.—PROCESS FOR TREATING ORES. James Ainsleigh McLarty, Toronto, Ontario. Treating and reducing ores by heating a mixture containing a carbohydrate and a hydrocarbon to a temperature materially below a red heat, igniting the gases and vapors thereby produced and treating the ore with said ignited gases and vapors.

1,080,113.—HEATING MOLTEN ELECTROLYTES. Franz von Kugelgen, Holcombs Rock, Virginia, and George Oulton Seward, East Orange, New Jersey, assignors to Virginia Laboratory Co., New York, New York.

An electrolytic cell having a heating means, comprising a hollow body immersed in the electrolyte and means for heating the same by burning a combustible therein.

1,080,223. CENTRIFUGAL ORE CONCENTRATOR. Edward C. Latchem and Lewis W. Pollock, Oakland, California. A revoluble vessel for centrifugal ore concentrators comprising a body having a plurality of upwardly extending annular steps formed upon its outer wall, the upper surface of the outermost step being outwardly and downwardly inclined, and an upstanding flange formed upon the extreme outer edge of said latter step.

1,080,059.—PROCESS FOR PRODUCING CLEAN OR DEOXIDIZED METAL SURFACES. John Adams Hatfield and Charles Robert Yates, Newport, England.

Acting upon a metal surface while in a highly heated state with silica to clean the surface and to form thereon a removable protective coating, then coating with a metal to remove this protective coating, and uniting the cleaned surface with the coating metal.

1,080,102.—PROCESS OF REDUCING ZINC COMPOUNDS. Elisha B. Cutten, Erie, Pennsylvania. A process of reducing zinc compounds free from slag-forming materials which consists in subjecting them, in the absence of fluxing material but in the presence of carbon, to a temperature ordinarily sufficient to vaporize metallic zinc and under a pressure sufficiently high to prevent such vaporization, the zinc being thereby precipitated as molten metallic zinc, substantially as set forth.

1,072,992.—METHOD OF FORMING MOUNTINGS FOR METAL LEAF. Fred W. Rauskolb, Medford, Mass. Applying gold leaf by supporting the gold leaf upon a sheet having a non-adhesive coating to receive said gold leaf; protecting the outer face of said gold leaf with a coating of adhesive aizing sprayed thereon, and subjecting said gold leaf and said supporting sheet to a heated tool applied with pressure to the rear face of said supporting sheet against the work to receive the gold leaf.

1,073,271.—MINING MACHINE. Edwin Reuel Merrill, Columbus, Ohio, assignor by mesne assignments, to the Jeffrey Manufacturing Co., a corporation of Ohio. Side cut or long wall; the combination of a carriage, a cutter wheel projecting laterally from the carriage, a carrier for the wheel adjustable relatively to the carriage on a transverse horizontal axis, and a train of devices for adjusting said carrier, the said train having a flexible spring controlled connection between two elements thereof through which power for operating the carrier is applied, substantially as set forth.

1,079,362.—ORE-SEPARATOR. Albert M. Plumb, Platteville, Wis. An ore separating apparatus consisting of a separating chamber having a level, reticulated bottom and provided with means for maintaining separate columns of material communicating only at a point near the bottom of the separating chamber and with a discharge opening for each column, the lowest of these discharge openings being substantially higher than the highest point of communication between the columns; these discharge openings being so positioned that the weight of the columns of material, when each extends to the level of the discharge opening, will be equal per unit of cross sectional area;

means for supplying material to be separated to one of said columns and means for applying intermittent impulses of air to the entire bottom of the separating chamber.

1,072,977.—STOP FOR MINING CARS. James A. Nolan, Bowerstown, Ohio. In combination, a vertically moving platform, a stop mounted upon the platform and adapted to arrest the movement of a carrier, a trip mounted upon the approach to the platform and located in the path of the carrier, a cam mounted independently of the platform, connecting means between the cam and trip, and a lever mounted upon the platform and movable therewith and having one end arranged to operate the said stop and having its opposite end adapted to be engaged by the said cam whereby movement of the trip effects a depression of the stop.

1,078,779.—PROCESS FOR THE TREATMENT AND SEPARATION OF COMPLEX SULPHIDE ORES. Tormod Reinert Forland, Broken Hill, New South Wales, Australia. A process for chloridizing sulphide ores, of zinc, lead, iron, copper, nickel, arsenic, silver, and the like, which comprises treating the ore with chlorine gas, at a temperature at which the metals, with the exception of silver, are converted into chlorides, and certain of the chlorides are volatilized, and chloride of sulphur is formed and volatilized; passing said volatilized chlorides, together with any remaining chlorine and chloride of sulphur, and other gases into contact with a further amount of said ore, at a temperature at which the chloride of sulphur will attack said metal sulphides, and form chlorides of said metals except silver, and free sulphur and at which temperature certain only of said chlorides are volatile.

1,080,053.—CONCENTRATOR. John S. Finlay, Wallace, Idaho. A horizontally disposed shaft, means for simultaneously rotating and reciprocating it, a frusto-conical drum having an integral closure at its larger end and open at its smaller end, auxiliary mounted on the shaft for movement therewith, and wholly unsupported and interiorly unobstructed save by said shaft, an annular rib formed integrally with and interiorly of the drum and in slightly spaced relation to the closed end thereof to provide upon one side in connection with the drum an annular treatment chamber triangular in section and upon the other side in connection with the drum and closed end thereof an annular discharge chamber, the bottom of which is inclined at the same angle as the bottom of the treatment chamber, being in fact a continuation thereof, the bottom of said discharge chamber being provided intermediate of its width with a plurality of circumferentially spaced apart, radially directed discharge passages, and means for separately delivering pulp and water to the inside of the drum.

1,080,344.—PROCESS OF SMELTING METALS. John D. Hilliard, Albany, New York, assignor to New England Metal & Machine Co., Boston, Massachusetts, a corporation of Massachusetts.

Producing a purified metal which consists in the following steps: (1) mixing the necessary material directly at normal temperature; (2) feeding the mixture continuously directly into a constantly traveling body of heated gases; (3) maintaining a regular, continuous, and retarded advance of the mixture for a considerable distance through and in opposite direction to the flow of heated gases, so as to progressively absorb heat therefrom; (4) continuously agitating the material throughout its entire path of travel so as to expose every portion thereof to the action of the gases; (5) passing the mixture in its final heated condition, due to the action of the gases, into an enlarged generating and reducing chamber, without interrupting or retarding the generation or flow of gases therefrom into the preheating space of kiln; and (6) raising the temperature of the heated mixture so as to effect complete reduction, by means of electrical energy continuously conducted therethrough, while maintaining constant, free, and unimpaired flow of the gases therefrom over the incoming stream of material throughout its entire path of travel to the point of introduction.

Tube-Mill Discharge

Tube-milling is made more efficient by removing the ground particles as quickly as possible from the machine, immediately they are reduced to the required size. The Chalmers & Williams adjustable quick discharge is claimed to operate on this principle. It consists of a set of four lifter plates which are set between a perforated diaphragm plate covering the entire end of the mill and the discharge head. These lifters pick up the pulp which passes through the submerged portion of the perforated end plates, and the passage of the pulverized material through the mill is thereby accelerated. The total product from the tube-mill is then returned to a classifier, where the

ADJUSTABLE QUICK TUBE-MILL DISCHARGE.

oversize is again returned to the mill, while the undersize becomes the finished product. Each lifter is pivoted at the ends so that it can be turned like a shutter, by means of adjusting bolts, extending through the head as shown in the accompanying cut, so as to vary and regulate the quantity and size of material ground, thus making an adjustable quick discharge. When the lifters or shutters stand at right angles to the head as shown, they are at closed position and exert a maximum discharging effect; and when turned from this position, by the bolts, gradually to a position nearly parallel with the head, they are in the full open position, and the discharge effect of the lifters is diminished until entirely eliminated. Thus is obtained a wide range of product.

A Portable Sub-Station

The Berwind-White Coal Mining Co., of Windber, Pennsylvania, has recently added a 400-kw. Westinghouse portable sub-station to its equipment and is making an interesting use of it. A sub-station consists of apparatus for changing alternating current into direct current, and is necessary in mining work because direct current must be used for haulage in mines but cannot be transmitted economically over long distances. Hence, when the mine is situated at a distance from the power-station that serves it, electric power can be transmitted more efficiently as alternating current at a high voltage and then transformed to direct current in the sub-station.

The Berwind-White company is developing its outlying properties rapidly and needs direct current at points where permanent sub-stations are not yet erected. In order to prevent delays in the development, the use of a portable sub-station was decided on. This sub-station has the same equipment as a permanent installation, namely, transformers to step down to a moderate voltage the high-voltage current received from the transmission line, a switchboard, and a rotary converter, which receives alternating current and delivers direct current. This apparatus is mounted in a car resembling an ordinary freight car.

When the work at a new property reaches the point where direct current is necessary, the portable sub-station is hauled out to the workings, connected to the alternating current transmission system, and is started to work generating direct current. When the permanent sub-station is built, the portable one becomes unnecessary and is taken to the next development. A further use of the sub-station is to provide insurance against shut-downs. If accidents occur at any of the permanent sub-stations, the portable

outfit is sent to carry the load until repairs are completed. One portable sub-station, therefore, is practically the equivalent of a duplicate set of apparatus at each permanent sub-station.

Preventing the Spread of Flames

In spite of the advent of so-called fireproof buildings, the days of fires have not yet passed. No matter what precautions are taken, the lives of the workers have frequently been jeopardized by the rapid spread of flames through inflammable material, even though the blaze has been confined to a single floor. This condition indicates that the real solution to the problem of safeguarding life and property is to provide adequate means for extinguishing the flames before they have a chance to gain headway. One type of extinguisher, which is known as the 'J-M Fryo,' discharges, by means of compressed air, a liquid gas claimed to be 40 times as effective as water. No mechanical force is required to operate it, there is no pumping, no tearing off of caps, no unscrewing of nuts, and no turning upside down. All that is necessary is to hold it in an upright position and turn a small valve-wheel. This little fire-fighter, which measures 3 by 15 in., can be aimed and operated almost as accurately as the pointing of a finger. In many extinguishers the stream has such a force that it is often shot through the flames, a large part of it going to waste. The 'J-M Fryo' device throws a spray as well as a stream; the spray can be thrown a distance of 10 ft., the stream 25 ft. The spray will cover the entire blaze of the average incipient fire so that all of the liquid gas volatilizes. In so doing, the gas forms a dense combustion-arresting 'blanket' which is five times as heavy as air, and quickly envelopes the flames, displacing oxygen and extinguishing the fire. As the extinguishing fluid contains no moisture, it is a non-conductor of electricity and can be used in electric fires without danger of short-circuits. It can also be used on gasoline electric fires. The fluid is non-corrosive and will not cause rust. The 'J-M Fryo' extinguisher is manufactured by the H. W. Johns-Manville Co., New York, which Company has recently issued an interesting little book on the subject of fires, and will be glad to mail a copy to anyone interested.

Catalogues Received

The HESS FLUME Co., Denver, Colorado. Leaflet. 2 pages. Illustrated. 3½ by 6 inches.

JOHN A. ROEBLING SONS' Co., Trenton, New Jersey. 'The Wire Rope at Panama.' 12 pages. 9 by 12 inches.

HYATT ROLLER BEARING Co., Newark, New Jersey. Card, 'Hyatt Bushings.' Illustrated. 6 by 8 inches.

INGERSOLL-RAND Co., 11 Broadway, New York. 'Air Compressors: Steam, Belt, Electric.' 20 pages. 6 by 9 inches.

NATIONAL TUBE Co., Pittsburgh, Pennsylvania. Leaflet, 'The Kawnee Union.' 4 pages. Illustrated. 5 by 7½ inches.

The ENGLISH IRON WORKS Co., Kansas City, Missouri. Bulletin No. 200, 'Samson Junior Holst.' Leaflet. Illustrated. 8½ by 11 inches.

The BROWN HOISTING MACHINERY Co., Cleveland, Ohio. Catalogue E, 'Brownhoist Buckets and Tubs.' 63 pages. Illustrated. 6 by 9 inches.

SPRAQUE ELECTRIC WORKS, OF GENERAL ELECTRIC Co., 527-531 West 34th street, New York. Bulletin No. 247, 'Round Type Direct Current Motors.' 23 pages. Illustrated. 8 by 10½ inches.

AMERICAN ZINC ORE SEPARATING Co., Denver, Colorado. Booklet, 'The Profitable Handling of Ores Containing Zinc.' Describes the Huff electrostatic process. 10 pages. Illustrated. 6 by 6¾ inches.

The DENVER ENGINEERING WORKS Co., Denver, Colorado. Bulletin No. 1061, 'Open Front Stamp Mortar. Improved Ore Feeder.' 3 pages. Illustrated. 8 by 10½ inches. Bulletin No. 1062, 'Ovoca Classifier.' 7 pages. Illustrated. 8 by 10½ inches.
